

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

---	--

**W**ASPS, hymenopterous insects, typically belonging to the family *Vespidæ*, in which the head-shield is square and the mandibles or greater jaws short and toothed at their tips. The wings are folded once longitudinally when at rest. The antennæ of the males are 13-jointed, those of the females and neuters or workers 12-jointed. The abdomen is egg-shaped and often borne on the thorax by a slender stalk.

The true wasps differ considerably in appearance and greatly in habits. Some of them live in pairs and construct simple cells of mud which are attached to twigs, beneath stones, etc., and stored with paralyzed spiders and insects upon which the larvæ feed; others burrow into the stems of plants or the ground and provide for the young in a similar manner. All such are known as solitary wasps, to distinguish them from the social or colonial wasps, and are sometimes separated as a distinct family (*Eumenidæ*). The true social wasps are all paper-makers and their nests are sometimes of large size and shelter a great many individuals. Unlike the solitary wasps which are of perfect males and females only, the social wasps produce in addition a caste of "workers" or infertile females.

*Eumenes fraternus* is a well-known solitary wasp, easily recognizable by the long and slender pedicle formed by the basal segment of the abdomen, the short square thorax, and long jaws. Its nests are dainty spheres about half an inch in diameter constructed of mud pellets and attached, often several in a row, to twigs or walls, and sealed after being provided with a fertilized egg and a supply of caterpillars. *Odynerus* and several related genera having very similar habits have the abdomen sessile. They are often gaily colored and some of them place their mud cells within hollow galls or the deserted nests of other insects. *Raphiglossa* forms burrows in the pithy stems of briars and stores its cells with the larvæ of weevils.

Of the social paper-wasps the species of *Poistes* somewhat resemble *Eumenes* in the slender more or less petiolate abdomen. All of the numerous species build a single tier of cells supported by a central pedicle and unenclosed in a covering. Several of these species are very common and well known. The nests, which begin with a single cell, around which others are added with a large disc two or three inches in diameter, hang from a support by the stem of the original cell, so that the nest resembles an

inverted short-stemmed wine-glass. The grubs hatch from the egg laid in each cell as soon as it is finished, and the cells are lengthened somewhat as they grow. They are fed by the mother, and mature and fly in about three weeks. Those first born are females, and these daughters at once begin to assist the mother-wasp in caring for the young hatched later. In the winter nearly all the wasps die, but a few fertilized females hide in shelter-crevices and survive to found new colonies in the spring.

In *Vespa*, the hornets, the abdomen is broad, robust and sessile, and most of the species, which include the hornets and yellow jackets, are brightly striped with yellow on a black or brown-ground color. The members of this genus exhibit the largest and most highly developed wasp communities. A common large species is *Vespa maculata*, the white-faced hornet which builds the large oval grayish paper-nests so well known. Externally they consist of several loose covering layers pierced by an aperture at the lower end. The interior is occupied by horizontal tiers of combs, like floors in a house, supported by columns, and with passages between. Each cell is hexagonal, as in the combs of bees, but the material is paper. These tiers of cells are built in succession, the upper ones first. Sexually wasps are of three kinds, males, females and neuters, the two latter armed with an exceedingly venomous sting. The last are the workers in the hive; they also go out to bring in provisions for the community. Wasps are nearly omnivorous, feeding on honey, jam, fruit, butcher's meat, and any insects which they can overpower. A share of these viands is given to the males and females, whose work lies in the vespiary and in providing for the future progeny of the colony. The cells of a large nest may amount to more than 15,000. In these the females, which are few in number, deposit eggs, hatched in eight days into larvæ. These go into the chrysalis state in 12 or 14 days more, and in 10 more are perfect insects. The males do not work. Most of the workers, all the males and the old females, die at the approach of winter, and in the spring each surviving female, having been impregnated in autumn, looks out for a suitable place to form a new vespiary, and builds a few cells in which are deposited eggs destined to produce workers. The latter then assume the duties of nest-building, and the number of cells is rapidly increased to provide places for the eggs which the female continues

THE  
ENCYCLOPEDIA  
AMERICANA

NEW YORK

CHICAGO

trouble begins. In all cases noxious fumes are produced and escape unless the temperature is 2,000° F. or more, and freedom from offensive odors is gained only at the expense of fuel. The organic fumes must be decomposed and destroyed within the furnace itself and, therefore, the process must be one of complete combustion and not mere evaporation or distillation. When a small amount of garbage is mixed with a large amount of paper, excelsior, shop sweepings and waste coal and clinker the incineration process is neither difficult nor costly; and is permissible in the outskirts of a town or city where there are no neighbors within a mile to be troubled by the fumes which in practice always escape with the chimney smoke and come to the ground at a greater or lesser distance according to the force of the wind. Many city incinerators for this kind of waste destruction are in use in the United States and Canada; many of practically the same class have been in use in England for a long time, and from there the practice has extended to Hamburg and some other places; but none of these incinerators endeavor to burn pure garbage, but always the mixture above mentioned. As a matter of fact, there is enough heating power in a pound of dry garbage to evaporate the water from the next pound, and, therefore, there is no reason why a furnace cannot be so constructed that each pound of garbage may dry the next succeeding pound, and garbage thus be made to burn itself, with only enough added fuel to insure the destruction of fumes. The practice in cities which use incinerators is to collect household ashes with the garbage. These ashes average 20 to 25 per cent of unburned coal, and this is ample for the complete destruction of the garbage at a suitable temperature.

Garbage utilization processes all aim to extract the grease by cooking in steam or solution in naphtha, after which the solid material or fibre is dried and ground to form a fertilizer base. The recoverable grease amounts to about 60 pounds per ton of raw garbage, and is salable at about three cents per pound. The dry fibre averages 540 pounds per ton of winter garbage and derives its value from the presence of ammonia — 18 pounds @ 8c. = \$1.44; phosphoric acid — 18 pounds @ 1c. = 18c.; potash — 6 pounds @ 3½c. = 21c., or a total recoverable value of \$3.63 from a ton of raw winter garbage. Summer garbage is less valuable because it contains more water and less grease and fibre. The cost of treatment, when the quantity is large, is less than the value of the material recovered. In American cities the amount of garbage collected averages about a half pound per citizen per day; in Europe it averages less than a quarter pound. Many people object to keeping separate garbage cans because of the odors which arise unless the water is absorbed by a mixture of ashes, paper and other waste; but in a large city where garbage is collected daily, it is evident that material which has come from the table within 24 hours must be odorless and unobjectionable, and that the odors arise solely from the cans, and from them only because they are not regularly washed and kept clean. Some cities require the wrapping of garbage in substantial paper parcels. This not only makes for cleanliness but renders incineration very much easier. The per capita production of garbage in the United States varies

from 80 pounds (Buffalo, N. Y.) to 240 pounds (Rochester, N. Y.) per annum. In nine of the larger American cities the daily output of garbage varies from 331 pounds to 875 pounds per 1,000 of population. In 1914 the city of New York entered into a contract by which it was to receive \$62,500 for its garbage the first year; \$87,500 the second year; and \$112,500 annually for three years thereafter.

The cost of incinerating garbage in the United States ranges from \$250 to \$1,000 per annum per 1,000 of population, the average cost being about \$600. At Minneapolis the city's wastes are used to produce steam, which lights and heats the charities and corrections buildings, and in addition lights 31 miles of streets.

(4) Ashes are always available for lowland filling and steam ashes are particularly sought by builders for use in fireproof floors, as a foundation for the cement floors of cellars and as a substratum for sidewalks and flagging. The ash output amounts in the northern part of America to nearly three-quarters of a cubic yard per citizen per year and many efforts have been made to utilize its various constituents so as to save the cost of carting or boating it away for filling purposes. Ordinary household ash from anthracite coal consists of: Fine ash, 50 per cent; coarse ash, stone and clinker, 30 per cent; coal, 20 per cent. Such recovered coal has a ready cash sale, and while the daily value of the ash from a single building is probably too small to pay for its separation, yet the process may be profitable when conducted on a large scale, in proper buildings and aided by mechanical means of separation. This recovered coal has an average heating value of about 75 per cent of that of new coal and has many advantages as household fuel because of its ease of ignition and its freedom from dust, clinker and slate. In the borough of Manhattan, New York, the annual output of ash is per capita, 1,162 pounds, or 3,175 pounds per 1,000 inhabitants daily. This amounts to an average of 12,999 cubic yards in summer and 18,558 cubic yards in winter. The total amount to be handled annually is not far from 5,500,000 cubic yards, or 4,200,000 tons, and the amount of recoverable coal contained therein is not far from 1,050,000 tons. The cost of handling, on the basis of an average haul of three-fourths of a mile, is 96 cents per cubic yard. If the ash collections are kept free from street sweepings and garbage, the recovery may be made by a machine capable of separating coal from clinker; and the value of the recovered coal will be nearly sufficient to meet the expense of ash collection and disposal.

(5) The class of waste including general rubbish — cans, bottles, old rubber, paper, rags, bits of metal, etc. — is a perennial delight to scavengers, who withstand dust and smells in order to pick out these things from a mixed mass of animal and vegetable refuse. But since city authorities have learned to keep the different classes of waste separate, this rubbish has become a source of revenue to the city even after paying the cost of collection and sorting. Old cans are sold at \$5 per ton for their solder, tin and value as material for cheap castings. Bottles are of two classes, "registered" goods — bottles which have the proprietor's name blown in the glass — and plain bottles without names. The average

price, at the place of collection, for "registered" bottles, which by law may be sold only to their original owners, is one cent each. Plain bottles are put into barrels and sold to dealers at \$1.50 per barrel. Broken glass, too, has a market value of 10 cents per bag. Rubber scrap is worth 15 cents per pound at the rubber reclaiming factories. Waste paper, when clean, is worth from \$4 per ton for newspapers to \$40 per ton for fine white paper, the average price for the paper collections of a city being about \$9 per ton. Rags vary in price, as do papers, many of the rags being used for paper stock. These materials have such value that only a small proportion reaches the carts of the department of street cleaning. The large proportion is collected by house-to-house visitation by junk-cart men, of whom there are in the borough of Manhattan, for instance, some 400, whose purchases amount to about \$1,000 per day; and only the balance is collected by the department carts. In many cities the privilege of picking over the "dump" is sold to the highest bidder. In smaller places the pickers are free to exercise their trade for what they can make. An idea of the extent of the trade in these waste materials may be gained from the statement that the yearly collection of old rubbers in the United States amounts to about 17,000 tons, of which some 600 tons per year, worth \$50,000, are collected in the borough of Manhattan. Some of the other yearly collections in Manhattan are as follows: "Registered" bottles—principally syphon bottles, milk bottles and those used for carbonated waters, soda and beer—2,000,000, worth \$20,000; plain bottles, 30,000 barrels, worth \$45,000; waste paper, \$2,000,000 worth; rags, \$75,000 worth; bits of carpet, string, iron, brass, etc., to the amount of several thousand dollars more. Though, as said above, only a small proportion of these things goes to the waste heap, yet, since the department has provided separate carts for dry rubbish, the city has received annually nearly \$100,000 for the delivery of these collections to contractors at the docks. The various materials are delivered mixed from each cart, and some \$150,000 is paid annually by the contractors to laborers who sort the waste into separate piles, after which it is sold to various dealers. Allowing a reasonable profit to the contractors, it is probable that the amount received by them is not less than \$300,000. Therefore, these bits of scrap thrown away by the housekeeper have become worth \$100,000 by their collection at the receiving station, and have become worth \$300,000 by separation into their component parts. The city of New York now employs large motor carts with eight compartments for ashes along the sides and a V-shaped "story" above for rubbish. A crew of eight men operate the car. The garbage is collected separately by a smaller car, with a crew of three. Of the 50 largest cities in the United States, 37 require the separation by the household of garbage, ashes and rubbish. All the cities in New York follow this plan. Of the 158 cities listed in the last census of municipalities, 72 per cent collect their wastes by a municipal force, and 28 per cent let contracts for waste removal to private parties.

The problem of the general separation of waste materials is simple in the household, but

difficult in the community. It is all a matter of education in ethics and community economy and requires strict rules with sure penalties for infraction. If each member of the population would increase the salable value of his household wastes one-half cent per day by keeping these wastes separate, the total amount would be sufficient to defray all the expenses of the department of street cleaning in any city in the United States. (See STREET CLEANING). Consult Branch, J. G., 'Heat and Light from Municipal Waste' (Saint Louis 1906); Capes, W. P., and Carpenter, J. D., 'Municipal Housecleaning' (New York 1918); Matthews, E. R., 'Refuse Disposal' (London 1915); Morse, W. F., 'The Collection and Disposal of Municipal Waste' (New York 1908); Venable, W. M., 'Garbage Crematories in America' (New York 1906).

**WATAUGA ASSOCIATION**, in American history a name adopted by a party of settlers who established the first independent civil government in North America. In 1768, the Six Nations (q.v.) agreed to surrender all the lands between the Ohio and Tennessee rivers. The first settlers were largely from Virginia and the first settlement was made on the banks of the Watauga River in 1769. The Watauga Association, established in 1772 by John Sevier, James Robertson and others, subsequently grew to be the State of Tennessee. Under the title "Articles of the Watauga Association," a written constitution was drafted, the first ever adopted by a community of American-born freemen. See SEVIER, JOHN.

**WATCH HILL**, post-village in Westerly Township, Washington County, R. I., on the Atlantic Ocean, and about three miles southeast of Stonington, Conn. It is near Watch Hill Point, a promontory forming the extreme southwest point of Rhode Island. The place has a fine beach and ranks next to Newport and Narragansett Pier, in Rhode Island, as a popular summer resort.

**WATCHMAKING, Modern.** It is an accepted fact of horological history that the portable mechanism from which has been evolved the modern pocket watch had its origin in Germany. And until the last half of the 19th century the watchmaking industry was confined to a few European countries, particularly to Switzerland and England.

The methods employed by all European watchmakers involve a great degree of individual skill on the part of the various workmen, a skill which can be acquired only by years of application and experience. But as it is the custom in the watchmaking districts of Europe for the children of a family to adopt the line of work pursued by the parents, the acquisition of superior manual dexterity would tend to be both natural and easy. Such skill would, however, lie within narrow limits. For instance, the members of a certain family would for succeeding generations be engaged in the making of a given piece or portion of the watch, one family making wheels, another regulators, another dials, etc. The several parts produced by these various families being brought together by still others, who fitted them to each other and sold them in the form of completed watches. Practically the same methods were in use in the watchmaking dis-

tricts of England. But while watchmaking in England has to a great extent declined, the Swiss are still largely engaged in the business, but their methods have been materially modified through the introduction of American machines.

It may be properly said that Europeans made watches by long-used methods, while Americans made a radical departure from established ways and originated a system, the foundation of which may be briefly stated as the substitution of impersonal machines for the acquired skill of the individual workman. A half century of continued growth has given practical demonstration of the correctness of the theory on which this system was founded. It is conceded to have had its theoretical origin in the mind of Aaron L. Dennison, a young Boston watchmaker, who in 1849, after months of planning and endeavor, succeeded in enlisting the co-operation of Edward Howard and his partner, makers of accurate instruments of various forms. Having secured capital to the amount of \$20,000, they built a small factory in Roxbury, where about four years was spent in preliminary work and in the production of a few hundred watches. In 1854 a new factory was built in Waltham, Mass., about 10 miles from Boston. This factory, after numerous changes, and additions, now exists as the oldest watch factory in America and the largest in the world. Here really began the manufacture of watches on what is now known as the American system, so that it may fairly be said that modern watchmaking belongs peculiarly, if not exclusively, to America. We have said that the American system of watch manufacture employed machines as a substitute for the acquired skill of the individual workmen. The foundation of the system is that of practical uniformity in the form and dimensions of large numbers of any given parts of watch movements, so as to permit of interchangeability.

Manufacturing on the basis of interchangeability may be said to have been in its infancy at the middle of the last century. Doubtless that system had its finest exponent at the time in the United States armory at Springfield, Mass., where were manufactured muskets for the use of the army. Mr. Dennison believed that, notwithstanding the diminutive character of watch parts, as compared with muskets, it would be possible, by the employment of suitable machines, to manufacture large numbers of such parts of such exact uniformity as to be readily interchangeable. The original American watch factory was therefore planned on that theory. But to fully equip a watch factory with tools and machines capable of producing work in that systematic way, would involve the employment of very large capital. The original factory was not fortunate enough to command sufficient confidence of capitalists to enable it to do more than make a beginning, but accomplished enough to demonstrate the practicability of the system. Its development has, however, been continuous, until at the present time machine watchmaking has to a limited extent been adopted in Switzerland, while the old methods of manufacture in England have declined to such an extent that there now remains but a small per cent of the former business.

A watch is really quite a simple machine,

containing an average of about 150 distinct parts. By actual count it has been found that the production of all these parts requires over 3,700 distinct operations. It will, therefore, be readily understood that the manufacture of watches on an extensive scale is one of the most complex and exacting manufacturing problems ever undertaken. It calls for high grade talent in almost every direction, and involves an intricacy of detail which can be mastered only by years of study and experience.

This being the fact, it will be hopeless to attempt more than a brief and fragmentary description of a few of the manufacturing processes involved; and it should be understood that the methods employed and the means used are not identical in all American watch factories, but doubtless they are as diverse as the factories themselves. It will, therefore, be best to indicate the most advanced methods only, which in the nature of the case can be found only in a large factory, possessing the absolute requisite of plenty of capital; for high grade automatic machinery is of necessity quite expensive, while at the same time its productive capacity exceeds the requirements of a small factory.

Beginning then with the foundation of the watch movement—the "pillar plate"—it should be said that these larger parts (which in the cheaper grades of watches are of brass, and in the better grades are of nickel alloy) are made at brass mills, from dies furnished by the watch factories, and are received in the form of blank "punchings." After these blanks have been carefully cleaned they are placed in a tubular magazine located at one extreme of a "facing machine" directly beneath a "carrier," which is attached to the extremity of a swinging arm. When the machine is put in motion the carrier descends and grasps one of the plate blanks and lifts it clear of the magazine and swings around to a point directly in front of a suitable chuck or holder on a running spindle of the machine, which at that instant is not in motion. The carrier then descends until the blank is in exact line with the axial centre of the spindle. When in this position the chuck is opened to receive the blank, which is pushed into the waiting chuck, which immediately closes tightly upon it. The empty carrier then rises and swings to a position midway of its excursions. The spindle then begins to revolve at a suitable speed, and at the same time moves forward so as to bring the revolving blank into the path of a suitable cutting tool which at once commences to move toward the axial centre, cutting away a definite portion of the blank and leaving it with a perfectly flat and smooth surface. As soon as the cutting tool reaches the centre of the blank, it is withdrawn from contact and returns to its former position. At the same time a second carrier swings around from the opposite side and places itself directly in front of the chuck containing the faced blank; the grasp of the chuck is relaxed and the blank is pushed out of it and into the second carrier which at once swings around and deposits it in the chuck of a second running spindle—a duplicate of the first. In this second position the other side of the blank is faced; then a third carrier takes

5 Automatic Pinion Staff Turning Machine

the now double-faced blank and deposits it in a receptacle at one end of the machine.

As the movements of the three carriers are simultaneous, and the cutting tools move in unison also, it will be seen that notwithstanding the numerous operations which succeed each other, a completed blank is deposited at one end of the machine at practically the same instant that another one is taken at the other end. Slight modifications in parts of the machine provide for desired recesses on either one or both sides of the blanks. These machines do their work on plates at the rate of 1,800 per day, so that it will be seen that they are far too productive for any watch factory which is not organized for a large output.

Succeeding the facing operations, just described, comes that of drilling most of the numerous holes in the plate needful to receive the screws, pins, etc., for attaching the "top plate," "balance cock, pallet bridge," etc. The ordinary method of drilling has been to clamp the blank watch plate to a master plate or "drill jig," in which were the required holes of proper size and accurately located, which holes served as guides to the various drills required. But inasmuch as the number and location of holes in such a jig were necessarily quite limited there was involved the use of several jigs to complete the drilling on each and every watch plate. Of course also an operative was required to insert and remove the plates and to manipulate the drills. Following the operations of drilling there is required the "threading" or tapping of certain holes for the reception of screws. This operation involved the repeated handling of the plates.

D. H. Church, the mechanical superintendent of the American Waltham Watch Factory, in addition to other machines in great variety, invented an automatic plate-drilling machine capable of both drilling and tapping practically all of the holes in the watch plate, in which the only work of the attendant is to fill with blank plates the magazine at one end of the machine and remove them from a similar magazine at the other end, where they are automatically deposited, completely drilled and tapped. In some instances the operations performed on each plate number 135, and the plates are delivered at the rate of one in 90 seconds.

Following the drilling of the plates comes the turning of the required recesses in both sides to make room for some of the moving parts of the watch, such as the mainspring barrel and some of the wheels of the "train."

The automatic recessing machines are also provided with delivering and receiving magazines located at the extreme ends of the machines, and between them are a number of parallel heads each provided with a running spindle and "chuck," and in suitable relation to each a compound slide rest carrying a special cutting tool adapted to the work to be done. Carrying arms automatically take the plates from the magazine and the successive chucks and transfer them to the next in order. But this transfer must be done with the utmost exactness, for the plates must be so held in the various chucks that the axis of revolution shall in each successive operation be in a

new but definite part of the plate. Moreover, the plates are located and kept with utmost precision in their proper position by guide pins in each of the clamping chucks, which pins correspond in relative position with certain of the drilled holes in the plates. It is needful, therefore, that as the plate is presented to each succeeding chuck, its guide pins shall be exactly in the proper position to enter the hole in the plate. The attempt to attain the required exactness of movement was regarded at first as a bold one, but complete success justified the hopes and expectations of the inventor.

The other supporting plates of the watch are treated in the same manner as the pillar plates above described, their differing forms, of course, demanding correspondingly differing chucks and holders.

For numerous succeeding operations of boring, turning, milling, etc., special machines are provided, many of them being exceedingly interesting in their intricate movements, but impossible of any brief description.

The American system includes the production of every portion of the watch in one establishment, but in very few even of the American watch factories has this ideal been attained. The fact that certain components of the watch, such as dials, hands, mainsprings, etc., which do not demand extreme exactness in fitting, can be imported from Europe, or produced in special factories, has enabled a number of incomplete factories to turn out watch movements in considerable numbers, without the investment of large capital. But the original American watch factory is equipped for the uniform production of every part of the watch movement, down to the delicate little taper pins used to confine the ends of the hairsprings. By means of special automatic machines these little pins are made at a rate exceeding 50 per minute. Even the fragile enamel for coating the dials is manufactured from the raw materials; as also the pure gold ornaments used to embellish "fancy dials." These things, however, do not demand the extreme accuracy which makes watch manufacturing so extremely trying.

It may be proper at this point to speak of one feature of watch manufacturing which might seem to show incompleteness in the "system." For many years the original American watch company manufactured watch cases as well as movements. But as their watches grew in favor, new watch companies were created, and as those new companies did not attempt the making of complete watches, other factories were organized for the exclusive manufacture of watch cases. As movement making has increased, case factories also have been multiplied to an extent hardly warranted by the production of movements. All case factories, however, of necessity conform to the standards of measurement furnished by the movement makers, and those standards are so practically uniform that regular cases of all makers will fit corresponding movements produced by any of the regular watch companies.

This systematic method of manufacturing to standard dimensions is of exceeding importance to watch dealers, and the purchasing public also, as the customer is thereby enabled to

select a watch movement of any desired size or grade, and also to select from a variety of cases one of such style or weight as best suits his taste. The ability to make independent selections of movement and case is one of the advantages of modern watchmaking made possible by the American system.

The use of special machines was applied to the manufacture of the smaller portions of the watch much earlier than to the production of the plates, as above described; indeed, it may be said that some of the earliest machines employed were semi-automatic. But so radical have been the changes and improvements instituted within the last 15, and especially during the last eight years, that methods previously used can hardly be considered as modern watchmaking.

One of the most interesting of those which are strictly modern is one of the turning of the delicate arbor on which is mounted the most swiftly moving wheel of the entire watch, the "balance." The fact that this wheel moves with such rapidity, together with the fact of its location at the farthest point from the reservoir of power, in the mainspring, makes it absolutely essential that it should be subject to the least possible amount of running friction. Consequently the pivots of this "balance staff" are exceedingly minute. It is, of course, an absolute necessity that every portion of the staff, including the delicate pivots, should run absolutely true. Exact truth was a difficult attainment under the methods ordinarily used, although great care was used to avoid any stress or distortion of the staff, by a very gradual reduction of the blank, so that 10 to 14 separate turnings were required to complete a staff. By the most approved modern methods and machines, all of the required turnings, including the pivots, are performed before the completed staff is severed from the rod of wire from which it is made. So complete is the machine, and so accurate and rapid is its operation, that a staff is delivered from the machine each 90 seconds.

The pinions of various sizes, which compose so large a portion of the time train of the watch, are formed from the best quality of steel rods and, as this wire must of course have a diameter as great as the largest part of the pinion, it follows that a large proportion of the material must be removed to bring the pinion to its finish dimensions. An early method consisted in first cutting the wire into blanks of sufficient length, then to insert those blanks in a suitable chuck in the running spindle of a lathe and with a suitable tool to remove the metal from the projecting end so as to bring it to an accurate point or centre. The blank was then reversed in the chuck and the opposite end pointed in like manner. In some instances a portion of the excess metal was removed in connection with the operation of pointing.

Following this somewhat crude method of pointing and initial turning, came the invention and adoption of so-called "roughing out machines," in which a rod of wire is inserted in the machine which automatically cuts off, points and turns the blanks on both ends and delivers them uniform in dimensions and requiring only the slight finish turnings and the

cutting of the teeth when they will be ready for hardening and tempering.

A later form of machine has been devised, which takes a rod of wire at one end and delivers the pieces "finish turned" at the other end.

The finished blanks are then placed in a magazine or "feeder" in a cutting machine which automatically takes them one at a time and forms the teeth of the required number and shape, the work of the attendant being to keep the magazine supplied with blanks, and to examine the pinions occasionally in order to detect any imperfections; so that a single person can easily attend six cutting machines. For the greater convenience and comfort of the operator a chair is fitted to run on rollers on an iron track on the floor. These rolling chairs are also provided in connection with numerous other machines where a single person attends to a number of machines.

Within two or three years D. H. Church of the Waltham factory has created machines in which pinions are completely turned and the required teeth are cut. All the work being automatically performed, so that completed pinions are made, the last operation being to sever the finished pinion from the rod of wire from which it was formed. The exactness with which these machines operate makes possible the production of pinions which could not have been produced with tools and machines in previous use.

As each watch movement required from 30 to 50 screws it will be evident that for a daily product of more than 2,500 watches more than 100,000 screws would be required. By the earlier methods employed in American watch factories an active man could make from 800 to 1,200 screws per day so that more than 80 men would be required for the production of this large number. But within a few years screw-making machines have been devised which are capable of making from 4,000 to 10,000 screws each per day, and being entirely automatic in action, a single attendant is able to attend six or more machines.

The almost absolute uniformity in the operation of the most improved modern watch-making machinery insures a resulting product so uniform in quality and dimensions as to make needless the minute "fitting" operations which are indispensable in work produced by even the earlier American methods. So accurately is the work performed that many of the most delicate portions of the watch, whose exact performance is absolutely essential, do not come together until all the finished parts meet for the final assembling.

It may appear strange, but it is nevertheless a fact that, by modern methods, watches are not made by watchmakers, as that term is generally understood, but by machines, by which it is to be understood that the component parts of the watch are all fabricated by machines designed for that special use and purpose. When those individual parts are finished and collected so as to suffice for complete watches they are assembled for the first time and when each part is in its proper place and the watch is "wound" it is run for a period of one hour, which is sufficient to determine whether it is inclined to run faster or slower

than the standard rate. But when the numerous portions of the mechanism are made and assembled, the work of the skilled watchmaker begins; for he it is who by means of the skill and judgment, which are acquired by experience, is able to discover the individualities and peccadillos of each movement, and so remove any "crankiness" that its performance shall be satisfactory.

It has already been said that the manufacture of watches by modern, that is, by American methods, is a very complex business, involving the employment of large capital and demanding the highest executive and mechanical talent.

The enormous growth of the railroad business in the United States and the greatly increased speed at which trains are now run has made absolutely necessary a standard of time and a high degree of accuracy in the running of all time pieces which are in any way connected with the running of trains. These new and exacting requirements are met by high grade watches with special adjustments to position as well as temperature. The natural effect of the requirements of the railroad time service has been to establish a higher standard of accuracy in rate for watches for the general public.

It will be readily comprehended that the product of a well-designed and properly made automatic machine will be much more uniform in its measurements than could be possible with an individual workman, even one of the highest skill. But the most delicate parts of a watch demand a degree of exactness that is impossible of attainment by even the most delicate measurement of mere *size*. These delicate parts are those which constitute the "escapement" whose combined function is to control the speed of the entire mechanism. The demand for exactness in the vibrations of the watch balance wheel which govern its time rate allows of *no variation whatever*—it is *positive*. To obtain the required number of 18,000 vibrations of the balance per hour two factors are required to operate in proper co-ordination, viz., the balance wheel and its accompanying hair-spring, the requisite being the proper adaptation of the weight of the balance to the elastic force of the spring. But there are other factors which cannot be ignored in the attempt to secure the precise rate of balance vibration. The first of these is *temperature*. It is one of the laws of nature that metals expand under the influence of heat, and it is evident that with a given amount of driving power a large wheel cannot be moved as rapidly as a smaller one. This being the case it must follow that the speed of oscillation of a watch balance wheel must vary in rapidity as the size of the wheel is modified by the temperature changes which affect it, so that if nothing could be devised to counteract the normal effect of temperature changes, the speed of the mechanism would be constantly changing in conformity to varying temperatures. Fortunately a most ingenious form of construction of the balance wheel has made possible a means of self-correction, by which the form of the balance is made changeable, so that the expansion or contraction of the metals which compose the balance is so utilized

as to maintain the effective diameter practically constant.

The method by which this result is achieved will readily be understood by the help of the accompanying illustrations, in which Figure 1 shows two bars of metal of equal

Fig. 1.

lengths, when at normal temperature. The dotted lines indicate the relative amount of expansion of the two metals—steel and brass. Figure 2 shows the two metals joined by fusion. Figure 3 shows the effect of heat upon this bi-metallic bar—the greater amount of

Fig. 2.

expansion of the brass portion causing the bar to curve upward. If cold was applied instead of heat the bar would be deflected in the opposite direction (as shown in Figure 4). Figure 5 shows a watch balance, in which the arms

Fig. 3.

and the inner portion of the rim are of steel, the outer portion of the rim being of brass fused to the steel rim, the rim being severed at two points, near the arms, thus allowing freedom for the movement of the rim under

Fig. 4.

the changes of temperature. Figure 6 shows this balance when under the influence of heat. Figure 7 shows a complete balance, having a number of screws with relatively heavy heads located at varying distances around the rim of the balance. Figure 8 shows the finished

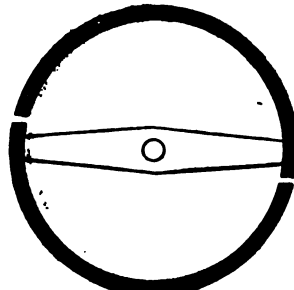

Fig. 5.

balance under influence of heat. The effect of heat is to curve the rim inward, thus reducing the size of the balance—the endeavor, of course, being to maintain the effective diameter unchanged. But the quantities involved are so extremely minute that additional and

more delicate adjustments must be provided. It will be observed that on Figure 8 the locations of the balance rim screws are numbered from 1 to 12 on each half of the balance. Also note that screws numbered 1 and 6 have shorter

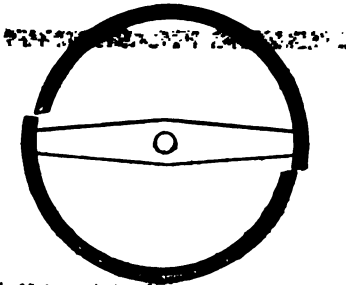

Fig. 6.

heads and longer bodies than the others. Also note that while these four screws are screwed in only part way, the others are screwed down to the head. These four screws are designated as "meantime screws," since by screwing

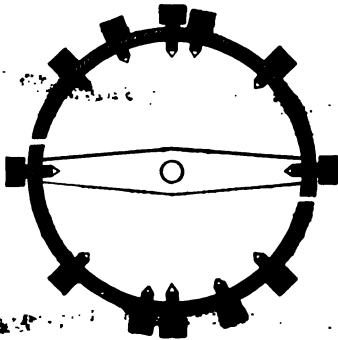

Fig. 7.

them in further the active diameter of the balance is reduced, that is, while the actual weight of the balance remains unchanged, a very minute portion of the weight is carried nearer to the centre of the balance, with the

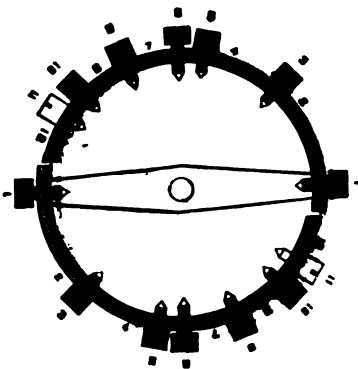

Fig. 8.

result of very slightly increasing the rapidity of its vibration. A watch balance vibrating precisely 18,000 times each hour will keep perfect time. But if it should vibrate 18,001 times an hour the watch would gain two and

two-fifths minutes in a month. Suppose that owing to a change in temperature the self compensation of the balance, as before described, should be insufficient, and the watch should lose, because of the increase in heat it would show that it was "under compensated." In such case it might suffice to simply change the location of some of the rim screws, for instance, to move screws number 4 to locations number 11. Such a change of location would not at all affect the actual weight of the balance, but would modify the vibrational weight, because when the screws were in location 11 they would be near the free end of the rim, and the distortion of the balance rim would carry more weight toward the balance centre and in effect maintain the effective diameter of balance and keep its speed of vibration unchanged. It must be realized that these changes are real, though so infinitesimal.

A second factor is that of position, as it affects the running friction through the influence of gravity, inertia and friction. These two factors of temperature and position are real, though somewhat intangible, and call for the exercise of the highest skill of the watchmaker and constitute what is called "Adjusting." The means for "temperature adjusting" have already been described, and as the processes of "position adjustment" involve such a variety of delicate manipulations of the balance and its pivots and also of the accompanying hair-spring, any attempted description of the process would be useless. It should be said that the obtaining of correct adjustment involves a series of 24-hour trials in the established extreme variations of 50°, i.e., between 40° and 90° Fahrenheit, and also in not less than three "positions" while the highest grades require to be adjusted to five positions.

A watch has been generally understood to mean a small timepiece in portable form, usually to be carried in the pocket. In later years, however, watches have been made in sizes and forms suitable for use as articles of convenience and ornament especially adapted for ladies' wear. One of the triumphs of automatic machinery has been the production of watch parts so extremely delicate as to make possible the construction of watch movements so small as to be covered by a dime. On the other extreme of size portable timepieces are made to run eight days. Movements of this size have come into extensive use on motor cars and as desk watches, etc. Movements of this size are also made of special grade and cased in the form of ship chronometers and are coming into extensive use for navigation, the United States government having hundreds of them in use.

A person who has not given careful thought or study to the matter of time-keeping can have but little conception of the extreme minuteness of the deviations from absolute perfection of rate which have been attained by modern timekeepers. On the other hand, to one who has given the subject careful consideration, it seems almost marvelous that mechanism can be created which makes possible the marking or determination of such almost infinitesimal time intervals as are taken into account in ascertaining the longitude of

any location for purposes of navigation, or even of securing safety in the daily movement of trains on our modern railway systems.

For these reasons it may be well to briefly mention some of the agencies which are employed in the complete modern watch factory, first for obtaining and indicating the exact standard time rate. It may perhaps be needless to state that the ultimate standard for the entire world is the *unvarying movement* of fixed stars across any given meridian. Nearly 40 years ago the Waltham Watch Company established an observatory equipped with a transit instrument and chronograph and also constructed two elaborate mean time clocks, which were most carefully mounted on special piers. In telegraphic connection with the observatory is the chronograph which is placed in the clock room, which is isolated from disturbing influences of vibration and noise and is also so arranged as to maintain automatically a temperature whose variation at all seasons of the year does not exceed one-half degree Fahrenheit. In taking the stellar observations the observer is able to record the exact instant of the passage of a given star across the local meridian upon a sheet of record paper which also records the vibrations of the standard clock, at one second intervals. So accurate do these clocks run that in a period of over two months their variation is less than three-tenths of a second. By means of an electric telegraph circuit the beats of the standard clock are given on telegraph sounders in all parts of the extensive factory. This method of time distribution is practically identical with that employed by the United States government in the naval observatory at Washington, D. C. In co-operation with the government wireless station at Arlington time signals were distributed throughout the entire country so that the standard time could be obtained by anyone who had a wireless outfit. On the orders of the government that all private wireless stations be dismantled because of the state of war existing with Germany, the Waltham Watch Company was compelled to resume the taking of its own observations for time, which had been discontinued when the government had organized its distribution of time signals by wireless means.

This feature of providing accurate timing standards is peculiar to modern watch manufacturing and so far as is known no watch factory in the Old World is equipped in this manner. But, on the other hand, the Royal Observatory at Kew, England, and the government observatory at Neuchâtel, Switzerland, undertake the testing of the limited numbers of watches submitted by the manufacturers of those two countries.

In conclusion, it may be said that notwithstanding the two or more centuries of priority and experience enjoyed by European watchmakers, their extreme conservatism has allowed them to be outstripped by the more progressive manufacturers of America, so that "modern watchmaking" is at the present time, and in its most advanced form, an exclusively American achievement.

E. A. MARSH,

General Superintendent American Waltham Watch Company.

**WATCHUNG, or ORANGE MOUNTAINS**, in New Jersey; a range of hills west of Paterson, Plainfield, and Orange, extending north and south, but curving westward at each end. Length, about 40 miles. There are three divisions of the range, each composed of trap-rock, which was a lava flow about the time other portions of New Jersey were in a more advanced stage of formation. The mud and sand covering followed and now the ranges are mostly shale and sandstone. The trap-rock, in places, forms elevations from 300 to 400 feet high, the soft sedimentary beds once enclosing it, yielded more rapidly to erosion. There is a similarity in the material composition of the Watchung Mountains and the Palisades, the difference being more in the direction of the original lava flow. The Palisades sheet was not a surface flow, but was forced between the sedimentary beds.

**WATER**, a universally diffused liquid, the true nature of which was not discovered till toward the close of the 18th century. In 1781 Cavendish carried out a series of experiments by detonating mixtures of common air and hydrogen or dephlogisticated air, as it was termed. He showed that by regulating the relative quantities "almost the whole of the inflammable and dephlogisticated air is converted into pure water." Although Cavendish showed experimentally that water is produced by bringing together oxygen and hydrogen, yet to Lavoisier, who received information regarding Cavendish's experiments, must be assigned the merit of interpreting aright the experimental results, and of proving that water was a compound substance—a compound of hydrogen and of oxygen.

Water may be produced by exploding a mixture of two volumes of hydrogen with one volume of oxygen at a temperature above 1190° F. Below that temperature the gases will not unite. It may also be produced by passing hydrogen over the heated oxides of several of the metals—and in various other ways. It exists, although never in a perfectly pure state, in immense quantities in nature. The composition of water has been determined by two distinct methods: (1) by volumetric synthesis; (2) by gravimetric synthesis. In volumetric synthesis of water measured volumes of pure dry hydrogen and of pure dry oxygen are mixed and the mixture is exploded by the electric spark while standing over mercury; the residual volume of gas is then measured; it is found that two volumes of hydrogen invariably unite with one volume of oxygen. In the second method a weighed quantity of a metallic oxide (usually cupric oxide) is decomposed by means of pure dry hydrogen at a high temperature and the water which is produced is weighed. The decrease in weight of the oxide gives the quantity of oxygen in the water formed; while the difference between the total weight of water and the weight of the oxygen gives the weight of hydrogen used. It is found that 16 parts by weight of oxygen are always united with two parts by weight of hydrogen to form 18 parts by weight of water. In the scale in which 16 is adopted as the atomic weight of oxygen the formula of water is H<sub>2</sub>O. The molecular weight of water has been variously

decided upon; first as 18, later as 36, and it is now accepted as probably 72.

Water is a tasteless, inodorous liquid, under usual conditions, colorless; but when a great thickness of it is examined, as in looking endwise through a pipe filled with it, it is found to have a distinctly blue tint. At all temperatures below 32° F. it is a solid and at all temperatures above 212° F. it is a gas. When water at 32° is heated it contracts until it reaches the temperature of 39.2°, after which it expands; conversely, when water at 212° is cooled it contracts until it reaches the temperature of 39.2°, after which it expands; 39.2° F. is called the point of maximum density of water; the specific gravity of water is greater at this than at any other temperature. The fact that water expands on cooling from 39.2° to 32° is a most important one. If a sheet of fresh water be cooled, the upper layers become more and more dense; they, therefore, tend to sink, and so fresh surfaces are exposed to the cooling influences. But when the temperature of the mass of water has reached 39.2° further cooling of the surface causes an expansion of the upper layers, which continues until these solidify into ice; these layers of cold water consequently float upon the warmer water underneath; hence it is impossible for the mass of water to suddenly freeze throughout. When water passes from the liquid to the solid state it expands to the amount of about 1-11th of its volume; that is, one volume of water forms 1.0908 volume of ice. This expansion is sufficient to bring about a large quantity of mechanical work, and to it the bursting of water-pipes during frost is to be largely traced. When solid water becomes liquid, or when liquid water becomes gaseous, a considerable quantity of heat is absorbed and disappears, or, as the expression is, is rendered "latent." Steam issuing from boiling water is no hotter than the water itself; water formed when ice is melting is no hotter than the ice itself; yet heat is being communicated to the ice and to the water. The latent heat of water is 79 thermal units; the latent heat of steam is 536 thermal units, although by the thermometer the temperature remains unchanged. In other words, in order to convert unit weight of ice at 32° into water at 32° a quantity of heat must be communicated to the ice, which, if communicated to unit weight of water at 32°, would raise its temperature to 79° C. In order to convert unit weight of water at 212° into steam at 212° such a quantity of heat must be communicated to the water as would suffice to raise the temperature of that weight of water through 536° C., or 536 times that weight of water through 1° C. Before water can become steam the upward pressure of its vapor must overcome the downward pressure of the atmosphere; hence it follows that the boiling point of water is conditioned by the atmospheric pressure. Water boils at a much lower temperature on mountain tops, where the pressure is comparatively small, than in the valleys. Water is almost incompressible. At 32° it is diminished in volume only by the fraction .0000462 for each atmosphere (15.7 pounds) of pressure added.

The solvent power of water is very large. As a rule hot water dissolves larger quantities

of solid matter than cold. Water is found in nature in many forms—vapor, dew, hoar-frost, rain, hail, snow; besides the several distinct variations of spring water, well water, river water, surface water, sea water, etc. As has been mentioned it is never found in a state of purity. Analyses of dew and hoar frost show from 2.64 to 8.00 parts of solid impurities in 100,000 parts of water. These are organic carbon, organic nitrogen, ammonia, nitrates and nitrites, chlorine, lime and magnesia. These substances have been held in solution in the vapor of water in the air. Snow will gain in ammonia content the longer it lies on the ground.

Rain water, when collected before it touches the earth, contains only such impurities as may be derived from the atmosphere, chiefly consisting of oxygen, nitrogen and carbon dioxide, with more or less nitric acid and ammonia in the case of thunder showers. The rain water of towns contains comparatively large quantities of sulphurous and sulphuric acids and of soluble salts. The amount of these substances may be taken as an estimate of the comparative purities of the atmospheres of different towns. Rain water collected near the sea is rich in chlorides. Samples of rain water taken in a farming country near the sea have shown 42.8 parts of solid impurities per 100,000.

River water varies greatly in so far as the nature and quantity of the substances held in solution by it are concerned. The soluble constituents of river water are chiefly such as may be derived from the rocks through which the water of the springs which have fed the river has percolated and the amount of surface water it has received owing to storms. The dilution of the original spring water by the continual influx of tributaries reduces the relative quantity of solid matter held in solution, while the escape of carbon dioxide during the exposure of the surface water to the air causes the precipitation of those salts which were held in solution by the aid of the carbonic acid. River water is often largely contaminated by the drainage of towns or of manufactories situated on the river banks.

Spring Waters.—The soluble constituents of spring waters are various. In some springs the quantity of dissolved solid matter is but trifling, while in others it amounts to 2,000 grains per gallon. Spring waters are usually divided into classes in accordance as one or other dissolved constituent predominates. See MINERAL WATERS.

Sea water is essentially an alkaline chlorinated water. The quantity of solid matter held in solution varies in the waters of different seas. Inland seas, as a rule, contain less solid matter than the ocean; thus the solid content of the water of the Black Sea amounts to about 1,760 parts per million, while that of the Baltic averages 17,700, and that of the Atlantic Ocean 36,000 parts per million. The substances held in solution in sea water are chiefly chlorides and sulphates of sodium, magnesium and potassium, together with iodides, bromides and carbonates, chiefly of potassium and calcium.

Use of Water.—In considering the suitability of a water for domestic use attention should be principally paid to (1) the source of the supply, (2) the total solid matter held

in solution by the water, (3) the organic matter held in solution and (4) the action which is likely to be exercised on the water by the means of supply. In examining the source of a water supply attention should be paid especially to the proximity of drains or sewers of any description, and to the likelihood of contamination from these sources. The nature of the soil through which the water percolates should also be inquired into. The solid substances held in solution by a sample of water may be estimated by evaporating a measured quantity of the water to dryness in a platinum basin heated by steam and weighing the residue. From a knowledge of the total solids in a water, unaccompanied by any further information, no reliable conclusion as to the suitability of such a water for potable purposes can be deduced. In seeking to determine whether a sample of water has undergone contamination with hurtful organic matter the following points are to be more particularly attended to: (1) Estimation of the amount of chlorine, whether existing as hydrochloric acid or as a chloride; (2) estimation of ammonia; (3) estimation of nitrates, and (4) detection and estimation, if necessary, of poisonous metals. The presence of an undue amount of chlorine generally points to contamination with animal matter. Pure waters do not as a rule contain more than three to four grains of chlorine per gallon. It must, however, be borne in mind that such waters as flow through a soil rich in chlorides—such, for instance, as the waters found in the neighborhood of salt-beds—always contain large quantities of chlorine. The sudden appearance of chlorides in a water previously free or nearly free from these substances points to animal contamination.

Ammonia may be obtained from most waters by distillation after the addition of a little sodium carbonate; when the whole of this ammonia has been driven off it not unfrequently happens that the addition of an alkaline solution of permanganate of potassium and heating results in the production of a further quantity of ammonia. The ammonia obtained by the first distillation is usually spoken of as "free ammonia," while to that obtained by the second distillation the name of "albumenoid ammonia" is given. The presence of even small quantities of albumenoid ammonia points unmistakably to organic contamination. Such ammonia is derived from the decomposition, by the agency of the alkaline permanganate liquid, of nitrogenous matter of animal or vegetable origin. Pure water should not contain more than 0.10 parts of "free" ammonia per million, nor more than 0.08 parts of "albumenoid" per million.

If nitrogenous matter has become thoroughly oxidized it gives rise to the formation of nitric and nitrous acids. The presence of these acids or of their salts, therefore, generally points to previous contamination of some organic nature. As, however, these things are the harmless—that is, in the quantities in which they occur in waters—products of the decomposition, and, therefore, of the removal, of hurtful substances, their presence, even when in comparatively large quantities, ought not of itself to condemn a water. The poisonous metals which are most likely to occur in drinking waters are lead and

copper. These may be easily detected and estimated even when present in exceedingly minute quantities. For details of the analytical methods of water analysis reference must be made to manuals of applied chemistry. It is evident that in a water analysis we look for symptoms of a disease; not for substances which are in themselves hurtful, but for substances whose presence is associated more or less invariably with others, the action of which upon the system cannot but be pernicious.

In storing water for domestic purposes the water may undergo contamination from the vessels containing it or from proximity to drains or other places emitting noxious gases. It is certain that water exercises a solvent action upon lead; but our ordinary leaden water pipes and tanks become coated with a comparatively insoluble compound of lead, so that the danger of contamination from this source is not great. Hot water should never be stored in leaden tanks; it very quickly corrodes and dissolves the metal. Aerated waters act rapidly on lead; for this reason they should never be prepared or stored in leaden vessels. The solvent action of water on copper is very small. The system of storing water for drinking or cooking in cisterns close to, or even communicating with, the house drainage system, is a very bad one. (See SANITARY SCIENCE; PUBLIC HEALTH). In some circumstances, as in the case of swimming-baths, large quantities of water have to be heated to a certain temperature and kept at the same for a considerable time while the water has to be maintained in a due condition of purity. For industrial purposes also most waters require purification of a kind, depending upon the processes of manufacture in which they are employed. The most common treatment is that known as "softening" for the removal of lime and magnesia carbonates, chlorine and other lesser impurities. See WATER SOFTENING; WATER SUPPLY.

#### WATER, ITS RELATION TO DISEASE. See WATER SUPPLY.

**WATER BABIES, The.** This story, by Charles Kingsley, written originally for the amusement of his youngest son "and all other good little boys," and published in 1863, remains perhaps the most popular of the author's works, with the possible exception of the historical novel 'Westward Ho.' It is on the face of it a fairy story. Tom, a little friendless chimney sweep, falls asleep in a fine house where he is working and is transformed into a water baby, being in most respects like a land baby, except for the presence of gills and other necessities of aqueous life. As a water baby he has many charming and attractive adventures of the kind since made more popular as well as more fantastic through Lewis Carroll's 'Alice in Wonderland.' In addition to these merely odd happenings, the book is, characteristically, a treatise on belief and education. As in 'Alton Locke,' 'Yeast,' 'Westward Ho,' 'Hypatia' and other Kingsley novels, there is a fundamental moral thesis. In this book it is that one must not be too prone to dispute the existence of this or that simply because he has not seen it. This idea comes out most clearly in the clever argument of Kingsley's to demonstrate the existence of water babies. From this

point of view the book is a vivacious argument for faith, designed on the one hand to make readers less assertive and dogmatic and also to render them more receptive of the underlying, if undemonstrable, mysteries of the Christian religion.

WILLIAM T. BREWSTER.

**WATER BALANCE**, an oscillating pendulous frame, having a series of troughs in vertical series and inclined in alternate directions, so that, as the frame oscillates, the water dipped by the lower one shall be poured into the next above, which, on the return motion, shall pour it into the next, and so on.

**WATER BAROMETER**. See BAROMETER.

**WATER-BEARS**. See TARDIGRADA.

**WATER BED**, a watertight mattress or bed for relieving any partial pressure of the body of a patient long confined to bed and so preventing the formation of ulcers which arise from such local pressure. One form is that of a trough half-filled with water, covered by a loose lining of india-rubber sheeting attached all around to the upper edge of the trough so as to be watertight, a mattress being laid between the invalid and the lining. Another form is that of a large waterproof bag which is laid upon an ordinary mattress and half-filled with water, the weight of the body resting upon this directly or with bed clothes between.

**WATER-BEETLES**, the numerous species of beetles which inhabit water. A common mode of life does not indicate blood relationship, and the various aquatic beetles belong to a number of quite distinct families. Besides those which are aquatic throughout their lives quite a large number of beetles live in or near the water only during the larval period. The strictly and permanently aquatic beetles belong chiefly to three families. The diving beetles (*Dytiscidae*) are predaceous throughout life and represent in the water the *Carabidae*, to which they are somewhat closely related, on land. The legs in these insects are adapted for swimming, the two hinder pairs being flattened and fringed with hairs. The body is oval and flattened. The mandibles are short and strong and the thorax is broad. The front legs are short and the antennæ long and filiform. In the genus *Dytiscus* the tarsi of the males are wide, flat and provided with sucking discs, while those of the females are unmodified. The females are of two forms, the one having the wing-covers smooth, the other grooved. The head is short and received into the thorax. *D. fasciventris* is the common water-beetle of our ponds. These insects carry a supply of air for breathing beneath the *elytra* or wing-covers. At evening they fly in the air. They are eminently carnivorous in habits and feed on other insects. The larvæ are active creatures and are also aquatic; their noteworthy rapacity has gained for them the name of water-tigers, which they well merit, for they will not hesitate to seize in their sharp sickle-like jaws any insect-larvæ, small fish or tadpole that comes within reach, and after draining its juices discard the dead body. The tail is terminated by a pair of respiratory tubes which are raised above the surface of the water to effect respiration. Be-

sides this large species the family numerous small ones having similar antennæ. The other two families have club-shaped of filiform antennæ.

The *Gyrinidae*, or whirligig beetles, 1 antennæ short, the front legs long, clav in the males provided with a spongy second and third pairs of legs very short and paddle-shaped, and the *elytra* do n the tip of the oval body. They deri familiar name from their peculiar habi scribing circles on the surface of the pe inhabit. When alarmed these insects the bottom and anchor themselves for by means of the strong front legs, carry them a small bubble of air on the abdomen. Owing to their smooth, p oily surface they are unaffected by ur The facets of the compound eyes are into two groups on each side, one ad vision in the water, and looking downw other for looking upward in the air— portant adaptation to the peculiar mod of these insects on the surface. When the whirligigs emit from the joints a strong-smelling milky fluid. Al *Dytiscus* larvæ, the young of the wu— predaceous, their appearance is tot ent; they are of slender form and, i a single pair of caudal respiratory gills, they bear 10 pairs of fringed la on the sides of as many abdominal Several other genera and species are in ponds.

The largest of the common wate belong to the family *Hydrophilidae*, v includes numerous small and inconspic uous. In the form of the body and the oar-like middle and hind legs they re *Dytiscidae*, from which all the member family are distinguished by their short clubbed antennæ. The eggs are deep silken cocoons attached to water-plants ried by the female. In general resemble water-tigers in form, the larvæ have thicker, solid jaws, much less prominent respiratory tubes and are less active, altho them, carnivorous. They pupate in bu the banks of the ponds which they The great water-beetle (*Hydrophilus laris*) is a pitchy black polished beetle and a half long, often seen flying at during the day rising to the surface weed-grown ponds for air and, un *Dytiscidae*, usually resting head upw adult life they forsake the predaceous and animal diet of their larvæ and scavengers, finding their food chiefly vegetable debris at the bottom of pon inhabitants of fresh-water ponds and are better suited to life in an aquari these beetles and few present a greater or more interesting habits. Consult works, especially Miall, 'The Natural of Aquatic Insects' (New York 18 Kellogg's 'American Insects' (New 1909). See FRESH-WATER INSECTS.

**WATER-BOA**, the anaconda snake. BOA.

**WATER-BOATMAN**. See B WATER-BUG.

**WATER BRASH**. See PYROSIS.

**WATER-BUG**, an aquatic bug of the hemipterous family *Notonectidae*. The hind legs are long and adapted for swimming by being provided with a fringe of stiff hairs. The body is prismatic in form, convex above and flat beneath, and the head is as large and as wide as the body. *Notonecta* is the typical genus of the family and *N. irrorata* and *undulata* are two of the common species. These and others abound in ponds and streams, where they rest on their backs at the surface, occasionally striking out with a vigorous oar-like movement of the hind legs, or dive to the bottom and cling to plants or stones. They are constantly buoyed up by a film of air which surrounds the abdomen, partly entangled in a coat of close fine hairs, partly held between the wings and the abdomen in a space into which the spiracles open and partly between the joints of the abdominal and thoracic segments. On land the water boatman are at a disadvantage and progress by a series of spasmodic leaps; but they are agile fliers. As larvæ, nymphs and imagoes they are predaceous and, besides strictly aquatic insects, young fishes, etc., they attack and suck the juices of flying insects which happen to fall into the water or approach its margin to drink. Various other hemipterous insects, such as the water-scorpions (q.v.), are aquatic. The croton bug is not truly aquatic, but is called a water-bug because it frequents water-pipes in cities.

**WATER-CLOCK.** See CLEPSYDRA.

**WATER-COLOR.** See PAINTING, TECHNIQUE OF.

**WATER-COLOR PAINTING**, in contradistinction to oil painting, the use of water generally interfused with gum arabic as a vehicle for applying colors, very often transparently, to a white surface. Anciently, there were three distinct methods of water-color painting, and these were known as tempera, encaustic and fresco. Tempera, or as it was sometimes called, distemper painting, was common in early Italian art. (See PAINTING). The colors were ground and mixed with the beaten-up white and yolk of an egg, or with the white juice of the fig tree, and sometimes with ox-gall. Encaustic painting was a process in which the colors were mixed with wax and laid in a thin coating, then fixed by the application of hot irons. The early Flemish and Dutch painters attained considerable success by the use of water colors in the medium of tempera, long previous to the invention of oil painting by the Van Eyck brothers. The Italian frescoes are painted in water color, on damp plaster and retained their colors scarcely impaired for centuries. See FRESCO PAINTING.

But when we speak of water-color painting in a modern sense we refer to the aquarelle. The ancient Egyptians used water-color to decorate their papyrus rolls, and the monks of the Middle Ages employed it to adorn vellum manuscripts; but this was all impasto, not the transparent washes, as in modern English work. This process and manipulation was the outgrowth of the methods worked out by Paul Sandby (1725-1809) and advanced by Alexander Cozens, creating an entirely new type of fine art productions known as aquarelles. The former treatment of the water-color work on

white paper was really a species of sketching in outline certain scenes then filling in the spaces with water-color (color printing). In the aquarelles the brush supersedes the pen (or pencil). Thomas Girtin (1775-1802) perfected the method and produced pictures disclosing consummate genius, and the novel charm of light and shade in nature as a fine art with transparent washes was revealed to admiring connoisseurs. These were the precursors of a talented English school. In the English school there has been no exclusive use made of what is known as body color. The lightness and darkness of each tint have generally been determined by the degree of their dilution with pure water, not by their modification through an admixture of Chinese white.

In early painting the pigments employed were generally mineral earths or juices pressed from plants. The colors found in antique frescoes were few but permanent in value. In the Middle Ages chemistry came to the aid of the fresco painter and supplied him with many brilliant and permanent tints, which in some instances vied with the lustre with which the church window maker stained his glass. The modern water-color painter has gained innumerable additions to the color range of his palette, and the freshness, crispness and unerring certainty of his touch have been largely due to the beauty, clearness and permanency of the colors in which he has worked. Manufacturers have, indeed, vied with each other in providing him with pigments which shall flow smoothly from his brush and stand projected with nature's beauty upon his paper. While the modern water-color painter aims at producing his effects by means of transparent washes, artists have not always considered it illegitimate to resort to the use of body color in their efforts to impart to their work the depth and solidity of oil painting.

**Technique.**—The necessary apparatus of a water-color artist's studio is simple and consists of paper, drawing-board and drawing-pins (push pins), palette, pigments and brushes. Many use an easel, but a number rest the drawing-board on their knees or on an adjacent piece of furniture (table, etc.). To avoid the paper from crinkling or cockling when the water washes are applied it is necessary to stretch the paper, by wetting it with water and fastening it firmly to the board by pins or mucilage around the border. While there are differences of opinion as to what paper to select, there is a limit to the number of makes acceptable to any artist. All used surfaces, grains, textures, etc., are comprised in the following list: Whitman, Allenjé, Michallet, David Cox, Creswick, Varley, cartridge, Van Gelder, white Canson and Burlington.

**Pigments.**—The colors used by the early aquarelle masters were made up into little hard bricks (cakes) and were rubbed out in water on a porcelain surface, but a more recent, perhaps more convenient, form of pigment preparation consists of moist colors, requiring less manipulation before being ready for the brush. Light-red, yellow ochre, cyanine blue, ivory black and burnt sienna are the colors which are the mainstay of artists. From these basic pigments can be produced every ordinary color effect in nature directly or by blending. But, in these days of rapid action, many or most artists add an

array of other paints to the color-box, care being taken that they are not such as fade quickly in the light, as do prussian blue, antwerp blue, etc. French ultramarine (pure ultramarine being altogether too expensive), Indian ink, rose madder, sepia, oxide of chromium, vermilion and naples yellow are considered safe for use. Brushes are peculiarly a matter of choice of individual artists, their sense of touch differing greatly. The number selected is not so much a matter of importance as their being kept *absolutely* clean and carefully dried after use.

But the full capacity of the water-color medium was not known before the pictures of Joseph Mallard William Turner (1775-1851) (an early student of John Cozens' works and a constant coworker with Girtin till the latter's premature death), were exhibited to the world. His early water-colors were, indeed, low in tone and gloomy, though forcible and convincing. What he came to do in the way of color is shown best in his Venetian studies, originally made on the spot in water-colors. Turner, however, did not confine himself to the water wash; when he thought it necessary he employed body color in parts of his work, and even, on occasion, pastels; or it may be pencil or pen. But he never revealed to anyone the secrets of a technique which made him the greatest landscape painter in water-colors which the world has ever seen. The foundation of the Old Water-Color Society, in 1800, and of the new society, in 1863, gave a great impulse to the art, among whose representatives may be mentioned Copley Fielding (d. 1855); Peter de Wint (d. 1849); Samuel Prout (d. 1852), the master of architectural painting; David Cox (d. 1859) and the brilliant executer of Oriental genre, Lewis (d. 1876). Taylor and Landseer, as animal painters, found this a successful and pliant medium, and among the Pre-Raphaelites who were eminent aquarellists may be mentioned Rosetti, Madox Brown, Burne-Jones, Holman Hunt, and Millais.

**Prominent Aquarellists.**—A partial list of the aquarelle artists of the English school whose works are appreciated by connoisseurs at sales must include the following; there are, of course, a number of noted artists who use the water-color medium as a side issue for "studies" but do not specialize on aquarelles. Earliest masters: Alexander Cozens and his son John Robert, Girtin, Turner, De Wint, David Cox, J. S. Cotman, Copley Fielding, S. Prout, Devis, Hearne, Bonington, Rooker, the two Cleveleys, W. Payne and N. Pocock. Belonging to the latter half of the 19th century we have F. Walker, G. J. Pinwell, Sir John Gilbert, G. Cattermole, E. J. Gregory, M. Bircket Foster, J. M. Swan. Recent artists: R. W. Allen, Mrs. Allingham, Wilfrid Ball, F. Braungwyn, Sir Alfred East, G. S. Elgood, W. R. Flint, A. Goodwin, A. Ingram, F. E. James, H. Marshall, E. Nohle, A. Powell, A. Rackham, A. Wardle, Sir E. Waterlow, J. R. Weguelin, J. W. West, M. Fisher, M. Hale, Hughes-Stanton, Lamorna Birch, A. W. Rich, C. M. Gere, C. J. Holmes, etc.

In France, among able landscape painters in water colors, were conspicuous I. B. Isabey (1767-1855); Hubert, J. Ouvrié, Sué and Fort. They pretty generally employed body color (*gomache*) in their composition, the transparent wash being much less frequently employed in

France. In portraits, Olivier Grand; in painting and still life, Redonté (1759-1818) the best painter of this class France has ever produced. But the art was not tried to its full capacity until the oriental sketches of J. M. Delacroix (1798-1863) proved to the art world that there was something to be gained for fresher and more inspiring than the frigid classicism of David. His lead was followed by Descamps (1803-60), one of the ablest colorists and most original painters of the modern French school, who taught his countrymen that it was possible to represent in water-color the broad blaze of open sunlight in the sand-plain; or in the streets of Smyrna and Constantinople. The powerful genres of *varni* (1804-66) made a sensation even in France, the native home of water colors.

The German school of water-color painting began with the illuminating or tinting of copper plate engravings. An independent and distinct department of aquarelle came into the history of German art. The first important aquarellists in that country were Karl von Schwan and Edward Hildebrandt of Leipzig and Edward Hildebrandt of Leipzig — Viermann, Otto, Graef of Berlin, Hei Stöckles, R. Stieles of Munich and a circle in Düsseldorf, including Scheuren and M. Schwanke. The Berlin school kept up the traditions of German water-color painting. A new path was struck out by J. M. W. Turner who obtained a great following. He had a broad, frank and dashing style which was much admired. The Berlin painters, such as Franz Skarbina and Paul Mayerheim, vie with him in this method of handling. But the French aquarelle has never been distinguished by the lightness of touch, the brilliant and transparent coloring, the powerful and vivid landscape effects which we find in the productions of the English and French artists. Italy and Russia have the other hand have many skillful adepts in water-color art. The vivid coloring of such masters as Corelli, Zezzos and Mainella has a liveliness all its own and the creations of these painters are worthy of comparison with the most eminent workers in their department of art in other parts of Europe. The same may be said of the Russians, B. M. Kozlov, Bergholz, Karafin, Heftler, Jeg Pissemski and Ehrenon.

Water-color painting has always found a very living section of American art life. Vassili Verestchagin, the great Russian painter, was in America, he was astonished according to his own account, that native artists were not more alive to the possibilities of American scenery and American life as subjects for the pencil. He was not sufficiently acquainted with the history of art in America to which he had come a stranger, to be aware of the fact that local art had long flourished there. The Hudson River School of painting produced many noble transcripts of American scenery of that river, mostly in large canvases and by employing oil as a favorite medium but several of them have also executed masterpieces of art in water-colors after the style of the best masters. Among those who have produced some good water-color sketching among the sublime scenery of the West may be mentioned Albert Bierstadt, some of whose views are correct in drawing and rich in coloring, although they owe their original impressiveness to the novelty of the effects in atmosphere and

tain contour or coloring which they reproduced. The same in a less degree may be said of the drawings of F. E. Church. Neither of these painters was, however, as triumphant in water as in oil. The New York Water Color Club has done much to foster a revived interest in this most difficult yet most effective and delightful department of the painter's art and among the most successful of those who cultivate it may be enumerated James McNeill Whistler, John Singer Sargent, Childe Hassam, Abbey, Moran, Parton, Murphy, Parsons, Shurtleef, Tryon, etc. Louis C. Tiffany is a colorist of rare gifts and although his natural predilection leads him to the representation of still life, yet his water-color landscapes have a value of their own. Charles Sanderson is well known for his lovely water-color studies of the shores of Lake Michigan. At the end of the 19th century there was suddenly a new movement developed in this department, principally through the influence of John H. Twachtman, whose early death was a sad blow to the cause he had most at heart in his native country. In 1898 the Ten American Artists crystallized into a new school of painting in New York. As far as this movement was represented by Twachtman it stood for a distinct advance in water-color art. There can be no doubt that he reflected in the practice of his art the very best features of that style which in Europe was embodied in the work of Girtin, Cozens and Turner. Water-color painting in the United States numbers among its devotees many other great names. Homer D. Martin's few water-colors are of the highest value. Frederic Crowninshield shows in his water-colors a noble sense of the form of hills and cliffs and the greater forms of the landscape, as well as of tree-form. Winslow Homer's many water-colors are about as important a contribution to American art as any other group of works. They are extremely vigorous and impressive, they sell at high prices and among lovers of modern painting there are certainly none more esteemed. Winslow Homer is essentially a "painter's painter" and no single artist in the whole group is more admired by his fellow-artists. John La Farge's water-colors are what have chiefly made his great reputation. There are hundreds of them in private collections in Boston, New York and neighboring towns and the show of the South Sea Island collection at the Paris Salon in 1898 or 1899 occupied a hall especially set aside for it and made a great sensation. There is nothing in modern art more rich in color than these La Farge drawings, which were produced during the years 1865 to 1895 chiefly; for from that time he became thoroughly absorbed in decorating work, glass and the like. The work of Robert F. Blum and that of Irving R. Wiles commands the admiration of their brother artists. Francis Hopkinson Smith was a master of loaded color, that which is mixed with white (the French *gouache*). There are women artists who excel in water-color work of each kind.

**WATER-GAS,** a mixture of gases produced by the action of steam on incandescent carbon. The carbon first decomposes the steam, forming hydrogen and carbon dioxide, and the latter gas then combines with more carbon to form the inflammable carbon monoxide. Thus water-gas may be considered economically a mixture of hydrogen and carbon monoxide with certain impurities. Its especial value as a fuel lies in the fact that 90 per cent of its volume is combustible, while the ordinary producer-gas is but 30 per cent combustion. Pure water-gas is non-luminous, but it is rendered luminous by mixing with it various gases obtained from petroleum, the luminous mixture being known as carbureted water-gas. Two chief methods are employed for the manufacture of water-gas for illuminating purposes. In the first of these, the Lowe process, the preparation of the pure gas and the carbureting are performed in one operation. The apparatus consists essentially of a generator, filled with anthracite or coke, in which the non-carbureted gas is produced; a carbureter, a circular chamber lined with fire-brick and filled with a checkerwork of the same material; and a superheater, a taller circular chamber similarly filled. By means of air-blasts and the producer-gas from the anthracite of the generator, the fire-bricks of the carbureter and the superheater are raised to a red heat, and then superheated steam is passed through the incandescent carbon. The product at this stage is known as "blue water-gas" and burns with a very hot, non-luminous flame. It is useful for many manufacturing purposes. To make it available for illuminating the water-gas formed is carried over into the carbureter, where it becomes mixed with the highly carbureted gases formed by the action of the heated bricks on mineral oil, which is introduced from above. This process is completed in the superheater, and the carbureted gas is then ready for purification process in which the

sulphureted hydrogen and carbon dioxide components are removed. In the Wilkinson process the operations of making the gas and carbureting are separate. In the United States carbureted water-gas has largely replaced coal-gas as an illuminant, partly because of its brighter light and partly because it can be more cheaply manufactured. Illuminating gas made from coal is often mixed with carbureted water-gas in order to increase its illuminating power. The chief objection to the use of water-gas as an illuminant is the highly poisonous nature of one of its largest constituents, carbon monoxide. By keeping the percentage of this constituent down to 16 per cent of the total volume, the mixture is not more dangerous to inhale than ordinary coal-gas. See GAS, NATURAL.

**WATER GLASS**, a substance which, when solid, resembles glass, but is slowly soluble in boiling water, although it remains unaffected by ordinary atmospheric changes. It consists of soluble silicates of potash or soda, or a mixture of both. The soda glass has the formula,  $\text{Na}_2\text{O} \cdot 3\text{SiO}_2$ . A substance of this kind was first discovered, so far as is known, by Van Helmont in 1640. In the 19th century Dr. Johann Fuchs of Munich did much to improve the mode of preparing and applying it. Water glass may be prepared in two ways, called wet and dry. The former method is used where the proportion of alkali may be so large as 50 per cent, in which case the sand and alkali may be simply boiled together. Where a water glass richer in silica is required the mode of preparation consists in breaking down and calcining flint nodules, the fragments or particles of which are then added to a solution of caustic potash or soda, whereupon the whole is exposed for a time to intense heat at 60 pounds pressure. Sand may be used instead of the flint. According to the product when prepared in this way is viscid, and may be used in this state or further diluted. In this method of manufacture the caustic soda or potash may be replaced by the carbonate or the sulphate. Potash water glass is more soluble than soda water glass, and if both metals be present a still more soluble glass, called double soluble glass, is obtained. Among the purposes to which water glass is applied are painting on glass, coating stone, wood and other materials to render them waterproof or fireproof, glazing scenery and paintings, etc. It is also used mixed with sand to make an artificial stone, and it forms an ingredient indispensable in the manufacture of fireproof cements, such as are used in joining firebricks in furnace construction. For this purpose it is commonly mixed with lime. One of the most valuable of its applications is in the fixing of wall-paintings, by spraying with the water glass. They are thus rendered more durable than in the ordinary process of fresco-painting.

**WATER HAMMER**, the name applied in the laboratory to a vessel partly filled with water, exhausted of air and hermetically sealed. When reversed or shaken, the water being unimpeded by air, strikes the sides with a sound like that of a metal striking against glass. In hydraulics the term is used to designate the sudden rise of pressure in a pipeline due to the

check of flow of the liquid running in it—as by the sudden closing of a valve. The strain on the pipe and any motor connected openly with it is often very serious. The formulas which are used to calculate this strain are

$\frac{pr}{t}$  = the circumferential stress in the pipe walls; and  $\frac{pr}{2t}$  the longitudinal stress—where

$p$  represents the increase in pressure in pounds per square foot;  $r$  the radius of the pipe in feet; and  $t$  the thickness of the pipe in feet. The hydraulic ram (q.v.) operates by water hammer. The technics of water hammer is exhaustively discussed in Gibson, A. H., 'Water Hammer in Hydraulic Pipe Lines' (Manchester, England, 1908).

**WATER-HEMLOCK**, deadly poisonous plants (*Cicuta*) of the carrot family, known also by many other names, such as beaver-poison, spotted parsley, muskrat-weed and musquash-root, the latter names being borrowed from the muskrat, which inhabits such swamps as the *Cicuta* affects; and the odor of the roots of certain species of the latter also recalls the musk-scented rodent. *Cicuta maculata* is a tall biennial, reaching eight feet in height, with a rigid, hollow stem marked with purple lines, that grows in swamps and wet lands throughout the northeastern United States. The leaves are decomposed, even three-pinnate, having coarsely serrate leaflets, with veins apparently ending in notches instead of at the points of the teeth, as in ordinary foliage. The flowers are very tiny and white, in decomposed, terminal umbels, with unequal pedicels. The fruits are ovate-oblong, glabrous and slightly flattened laterally. The ribs are corky, the lateral ones being strongest. Spindle-shaped, tuberous roots cluster about the base of the stem, and are the cause of many deaths. They have an aromatic flavor and fleshy substance, and are frequently mistaken, especially by children, for the roots of sweet cicely, parsnips, artichokes, or even horse-radish, and are sometimes eaten for no particular reason except that they are fleshy and exposed by washouts, freezing or digging-operations. Even livestock are killed, not only by feeding on the tubers themselves but by drinking water poisoned by roots which have been crushed under the cattle's hoofs. The poisonous element in this *Cicuta* is an aromatic oily fluid, which permeates the whole plant, but is found chiefly in the roots, and probably contains the alkaloid conine and the bitter principle cicutoxin. When eaten *Cicuta* produces vomiting, colic, staggering and unconsciousness, and finally frightful convulsions which end in death. No chemical antidote being known, the only treatment possible is to cleanse thoroughly the digestive system, and treat each stage of the attack with such medicines as seem necessary. Cattle may sometimes be saved by timely and repeated doses of melted lard. The elongated spindling-roots of the Wyoming water-hemlock, *Cicuta occidentalis*, which in Montana is known as the wild parsnip, has a characteristic musky odor, and stock are poisoned either by the young plants or by the roots. Other species of *Cicuta* have a similar appearance above ground and are equally poisonous.

**WATER-HEN, or MOOR-HEN,** a rail (*Gallinula chloropus*), generally distributed throughout Europe, Asia and Africa. Its length is about 13 inches; back, wings, rump and tail rich dark olive-brown; head, neck, breast and sides dark slate gray; thighs and flanks streaked with white, belly and vent grayish white; beak yellowish, becoming red; naked patch on forehead red; legs and toes greenish-yellow, claws dark-brown. The female is rather larger and more vividly colored than the male. They frequent ponds covered with aquatic herbage, overgrown water-courses and the banks of slow rivers, swimming and diving with facility, assisted by an expansion of the membrane along the sides of the toes. The water-hen is representative of the sub-family *Gallinulinae* of the rail family (*Rallidae*) which comprises 30 or 40 species found in all parts of the world. In the United States they are generally known as gallinules or mud-hens, and are represented by the purple gallinule (*Tringa maritima*) and the Florida, or common gallinule (*Gallinula galeata*). The American coot (*Fulica americana*) is also frequently called a water-hen.

**WATER-HICKORY.** See HICKORY.

**WATER INCH,** in *hydraulics*, a measure of water equal to the quantity discharged in the 24 hours through a circular opening of one inch diameter leading from a reservoir under the least pressure, that is, when the water is only so high as to cover the orifice. This quantity is about 500 cubic feet. In irrigation, the term is used synonymously with "miner's inch," which is the volume of water which flows in one hour through an aperture one inch square, the sides being horizontal and vertical, under a head of six inches measured from the upper edge of the aperture. The flow amounts to 673.2 gallons per hour.

**WATER LAWS,** the body of legislative enactment and legal decisions governing the rights to the use of water. In comparison with the laws concerning ownership of land and of other property the water laws, particularly in the United States, are extremely complicated. There is a great amount of law with apparent lack of consistency in the prevailing legislation and decisions. The cause of this lies largely in the physical fact that water as a substance varies in quantity from day to day and until recent years the principles governing its occurrence and the methods of measurements have not been well understood. In fact they are still more or less of a mystery to many members of law-making bodies. More than this there has been an attempt to apply rules of law which while suitable for permanent or fixed objects are hardly applicable to a substance the component particles of which are ever flowing away and are ever renewed, but in fluctuating quantity. To illustrate some of the different conditions and viewpoints take first the case of a natural spring or pond on a certain tract of land. It is generally conceded that ownership of the land carries with it the full right to the use of this small body of water. If, however, the spring or pond discharges onto a piece of land belonging to another proprietor, it is obvious that the second owner has certain rights due to the

fact that the stream flows along or across his land. Under ordinary conditions the upper owner may not deprive the lower of his fair share of the water, at least for drinking purposes for man and beast. The stream flows on continually, joins with others and becomes a boundary line between proprietors. Each through his ownership of the land claims certain riparian rights in the flowing water. The stream finally becomes of such size as to be of importance to the whole community or State and the latter sometimes claims proprietorship in the bed and banks, these being held by the State for the benefit of the public. It finally becomes of navigable capacity, and, under the terms of the prevailing interpretation of the Constitution of the United States regarding commerce, the control is vested in Congress. In the older part of the country where, under humid conditions, there is usually ample water and to spare, the rule is that each riparian proprietor shall permit the stream to flow through or along his land undisturbed in quantity and unchanged or unpolluted as to quality—his rights being bounded by those of all his neighbors above and below, each having a fair share in the use of the water provided he does not interfere with rights of others. He may utilize the water for power if in so doing he does not overflow the lands of others nor interfere with established usages nor with the enjoyment of similar opportunities by others. If, however, a municipality finds it necessary to take water from a stream, it must be prepared to make compensation for any possible rights which may be interfered with. As a rule it cannot exercise the right of eminent domain outside of the borders of the State in which the city is located. It may be thus narrowly circumscribed and hindered from its best growth because of artificial restrictions imposed by State lines.

In the arid and semi-arid regions in the western part of the United States the common law of England, which has been followed in the humid East, is not in accord with the common necessities of the people. There it is possible to cultivate the ground successfully only through the artificial application of water. The lands will remain unproductive and population cannot increase unless the waters are taken from their natural channels to be spread over the ground and the stream channels left practically dry. The rights of riparian proprietors can be no longer observed, as in Eastern States, where under ordinary circumstances there is enough water for all. Out of the necessity of the people has thus grown an entirely different theory, namely, that of appropriation—this being limited to beneficial use, each appropriator being permitted to take usually only so much water as is needed for the irrigation of his land; even in this he may be required to show an economic use. In the case of two or more appropriators not finding enough water to satisfy their needs, the rule is usually enforced to the effect that first in time is first in right, although this rule is being modified in practice in accordance with larger equity, for example, if the first in time is at a place where there results great waste in getting

the water to him, consideration may be taken of the fact that to irrigate one acre thus situated many acres better located must be left dry.

The common law of riparian rights such as prevails in the eastern or humid part of the United States, but modified to a considerable extent, is recognized in California, Kansas, Montana and Washington. The civil-law doctrine declaring that the waters are the property of the State is contained in the constitution of Wyoming; similar declarations are made in the laws of Idaho, Nevada and Texas. By the constitution of Colorado the water of every natural stream is declared to be the property of the public and dedicated to the use of the people of the State. Similar declarations are contained in the water laws of Nebraska, New Mexico, North Dakota, Oklahoma, South Dakota and Utah. Under the so-called Wyoming system the water rights are in theory acquired by grant from the State. There is great difference among the Western States with reference to the control of appropriation. In some States this control is vested in a State board with right of appeal, however, to the courts. In others adjudication proceedings are initiated in the courts. Because of the difficulty of ascertaining the ordinary supply of water and because of the exaggerated claims which are made to its use there have arisen innumerable controversies so that in some parts of the arid region more money is being expended in litigation than in actual irrigation. In most States in which water rights are adjudicated by courts the law provides that all parties claiming rights to water from the same source shall be made parties to the action so that all rights may be determined in a single action. Without such provision, there may be an interminable succession of suits, A bringing B into court to determine their respective rights, then C coming in and upsetting the arrangements and so on through the entire alphabet. The interest of the public or of the State is not necessarily taken into consideration at any time.

There are conflicting theories which arise from a difference of opinion as to the origin of rights to water. Throughout a greater part of the East there is insistence upon the conception that all rights to the use of water abide in and are derived from private or personal proprietorship of land and that any attempt at the invasion of the sanctity of property will result disastrously. Nevertheless attempts have been made and are continually being made to preserve the rights of the public and by asserting the theory of State ownership and control of water, to set a limit to the broad claims of riparian owners. Farther than this there is still a third class who claim that the Federal government has the right and duty on behalf of all the people and for the general welfare to extend its authority beyond the narrow limitations of preventing interference with navigation and to legislate in such a way as to prevent this great natural resource from being exploited wholly for private gain, especially as to those waters which have not already been appropriated or put to beneficial use. There is continual attempt of riparian owners and of large

moneyed interests to extend and their control of water rights. At time efforts are being made by legislatures and by the Federal Government to enact legislation protecting the general interest in the proper enjoyment of water, air, is essential to all life whether animal or vegetable. The conflict between these opposing theories and views is shown in innumerable statutes and court decisions. Many of them apparently irreconcilable and unfortunate feature is that, besides the litigation, the largest and best waters of the country are not being given the consideration.

F. H.

**WATER-LILY**, a plant of the family *Nymphaeaceae*, especially of *Castalia* and *Nymphaea*. These are found in fresh, still waters throughout the temperate regions, and are often abundant. Some can be easily raised from seed which are hardy in the North and can stand a very low temperature without damage, but they may be encased in ice. They may be raised in tanks, or even in half-barrels, as ponds; but the tropical species, such as *regia*, require the warmth of a greenhouse or heated tanks, in our northern latitude. Water-lilies are handsome plants, or less orbicular, generally pelagic, floating or, more rarely, immersed, with flowers, of similar varying habit. The flowers have several sepals and many stamens and carpels, the latter distended or immersed in a thickened receptacle they may be white, pink, yellow or red, and are sometimes very fragrant. The berries are dehiscent, somewhat fleshy, and filled with nuts, or, in *Nelumbo*, the nuts are half sunk in a flat-topped, enlarged torus. The seeds are enclosed with fleshy cotyledons and are closely in pulpy arils. Water-lilies, of the time of Pliny, were considered to be of medicinal value to love-philtres. The most famous perhaps the giant or royal lily, *Vicinia* (q.v.). Another which is very large is the Austrian water-lily (*Castalia gigani*) is one of the finest of its genus. The flowers are sometimes a foot across, with many stamens, and the color is blue, or white, or tints. They do not close so early at night as do other water-lilies. The *lotus* (*Castalia lotus*) that was a favorite of the ancient Egyptians is often confused with the Indian *lotus* (*Nelumbo*), but is a blue flowered water-lily. It was used by the plant to the decorators of that country and copied it, and conventionalized its form for their architectural ornaments, and introduced it constantly into their paintings of life and customs. Its rootstock was served as a food. (See *LOTUS*). The pond water-lily (*Castalia alba*) is similar to the white flowers that are apt to open above the surface of the water, being supported by a stiff petiole. The flowers are not as large as those of the American pond water-lily (*talpa odorata*). The latter lovely lily floats on the water, with creamy-white petals in several circles, the inner gradually narrow and passing by various stages into large

in the centre. They expand in sunshine and close in the early afternoon. The fruit is ovate and haccate and ripens under water. The leaves, or lily-pads, a favorite food of deer, are ovate-orbicular, with a deep sinus, and have very long cylindrical stems of unvarying thickness, great flexibility and toughness. The thick, fleshy creeping rootstock furnished a brown dye for the early settlers, and was also used as a styptic and tonic. A variety of this lily is smaller and has rose-colored flowers. There are several other species of *Castalia* in the United States, including the handsome golden-flowered lily (*C. flava*) of Florida.

One of the most common water-lilies is the yellow pond-lily (*Nymphaea advena*) which blooms all through the summer, but is not very beautiful. The leaves are ovate, or orbicular, with a deep sinus at the cordate base. They may be either floating or erect, especially when the plant grows in tidal streams, and is likely to be left standing nearly out of water, upon the ebbing of the tide. These pond-lilies also are known as spatter-docks and frequently join with pickerel-weeds in obstructing a boat's passage to the shore, along which they stand in an extended ribbon. The flowers are flattened globes, made up of half a dozen thick, golden sepals, arching over the stamen-like sepals. The fruit is ovoid, somewhat constricted at the neck and contains edible seeds. The strong-growing Pacific Coast representative of the spatter-dock is the *Nymphaea polysepala*, known to the Klamath Indians as *wokas*. It is very like the Eastern species. When fully mature, the large pods burst open irregularly at the base, and the entering water, when it reaches the white, mealy interior in which the seeds are imbedded, at once starts a mucilaginous dissolution of it, which frees the seeds and allows them to sink into the water. These seeds were once a staple farinaceous food of the Klamath Indians, and are still a favorite delicacy among them. The squaws betake themselves in canoes to the lily-patches and pluck the full-grown pods while still hard, or scoop out those already dissolving with a wicker spoon. The latter are the more prized, and are deposited in holes in the ground, where the pods ferment and turn into a mucilaginous mass from which the seeds may be freed by washing. Or the seeds may be extracted by other methods. They are then prepared in various ways for eating, either as mush or meal, or merely parched; they are delicious cooked in this manner.

*Nelumbo nelumbo* is the Indian lotus; *Nelumbo lutea* is the American or yellow lotus of the Middle West. It is also called water-chinquapin, on account of its edible seeds. Consult standard authorities, especially Bailey, 'Standard Cyclopedia of Horticulture' (New York 1916).

**WATER-LOCUST**, or **SWAMP LOCUST** (*Gleditschia aquatica*), a variety of honey-locust indigenous to the Southern States. See **Locust**.

**WATER MARK**, (1) The mark or limit of the rise of a flood or the mark indicating the rise and fall of the tide. (2) In paper-making, any distinguishing device or devices appearing in translucent lines in the substance of a sheet of paper. It is produced by a pattern of wire

built upon the web and receiving heavy pressure from the rolls as the film of pulp passes through them while yet in a damp or pulpy condition. The water marks used by the earlier paper-makers have given names to several of the present standard sizes of paper, as foolscap, crown, elephant.

**WATER METER**, a mechanism by which the quantity of water or any other liquid flowing through pipes is measured and recorded automatically. They are of three general types — the "positive," the "inferential" and the "proportional" meters.

Positive meters measure the actual volume of the water, by the action of a piston working in a cylinder which is successively emptied and filled at the completion of each stroke. The cylinder being of known dimensions affords a measure of the quantity of water introduced. The pistons are either reciprocating or rotary, or of the oscillating or gyrating disc patterns and they may be single or double. When single, a weight or spring produces the return stroke, but in the case of the double arrangement, the reciprocal action of the two pistons is controlled by the action of each other, as in the case of a duplex pump. In rotary piston meters, which may also be of the single or double type, the pistons have interlocking faces and rotate in an air-tight chamber. Upon the outer surfaces of the pistons are a series of projections and recesses which correspond to similar shapes on the inner walls of the cylinder. The pressure of the flowing water causes the piston to turn so that a series of recesses or chambers in the cylinder are successively filled and discharged from the inlet to the outlet of the meter. When oscillating or gyrating discs are employed in the place of pistons, the wobbling motion of the discs alternately empties and fills the cylinder. Inferential meters measure the velocity of the flowing water by recording the revolutions of a turbine or other water-wheel attachment, and the quantity is deduced by computation from that record. Proportional meters measure a fractional part of the full flow and are, therefore, capable of being set on a small by-pass pipe which branches from and subsequently rejoins the main pipe, but being only approximately accurate their use is limited.

The registering mechanisms consist of a series of gear-wheels and dials. The flow of the water actuates the gear-wheels, and the number of revolutions are recorded on the dials. The arrangement of the mechanism converts the number of revolutions into any desired unit of volume, so that the reading of the dials is termed straight and gives the quantity direct, in cubic feet, the unit generally adopted, particularly in the United States.

The working parts of meters are made light and durable. Serviceability and accuracy are the qualities required, and in their design the support of the water pressure is employed to reduce to a minimum the loss of head, and the wear and tear of the working parts, and although a high degree of accuracy is not generally required, the meters are made sufficiently sensitive to measure the small flows incident to leakage. Hard rubber is generally used for the discs, and also for the rotary pistons of some meters, but where the liquids are hot, or consist of chemical solutions, brass is generally

employed. Possible damage due to clogging by the introduction of fish or gravel is prevented by various forms of strainers and sieves, while effect of frost is guarded against by frost cases.

There are several forms of meters which do not come under the general classes already described. Of these the "Venturi," constructed by Clemens Herschel of New York, in 1886, is the superior and most useful on account of its simplicity and durability. Its basic principles—the relation between the reduction of pressure and the increase of velocity of water flowing through a contracted pipe, was discovered by Venturi in 1796. In construction it consists of two conical shaped pipes with their smaller ends joined together by a collar or throat-piece, resulting in a shape similar to a pipe contracted at one point of its length. By gauging the pressure of the water at a point just before, and also directly at the point of contraction, and the relation of these pressures to the diameter of the pipe, the volume of the flow is computed. The tubes are usually constructed of cast iron or riveted steel; but they may also be constructed of masonry or wood. The length of the meter varies from 8 to 16 times the diameter of the uncontracted portion, while the diameter of the contraction ranges from one-fourth to one-half of the full diameter of the tube. They are made in sizes varying from two to about 100 inches, with practically no limit to the possible maximum size, but for practical use where meters of diameters less than six inches are required those with moving parts are cheaper. Waste-water meters are employed in connection with waterworks to measure the rate of consumption per unit of time, instead of the total volume. They consist usually of a disc placed horizontally in a cone-shaped chamber. The disc is lifted or lowered according to the greater or lesser volume of water passing through the pipe in which it is set, and being connected by a wire with counterweight and pencil which follow the movements of the disc, records the nature and amount of those movements on a paper carried by a drum which is revolved by clockwork. The vertical rulings of the record sheet indicate the time intervals, while the horizontal lines represents the units of volume. Since all the water consumed in a given district must pass through such a meter, by comparing the rates of consumption of the various districts, the causes of abnormal waste are readily determined and localized.

Another form of water meters, more particularly known as current meters, are employed in hydraulic engineering to measure the velocity and volume of flow of the waters in rivers, large aqueducts and sewers. See CURRENT METER.

**WATER-MOCCASIN**, a snake. See MOCCASIN.

**WATER-MOLDS**. See FUNGI.

**WATER MOTOR**. In its broadest sense the term is applicable to all forms of machines or systems of machinery operated by water under the force of gravity, or in other words, by which the energy inherent in a natural waterfall is utilized to perform mechanical work. There are three types of such motors, classified as (1) gravity motors; (2) pressure motors, and (3) impulse motors. Of these machines, the water-wheel (q.v.), the turbine (q.v.) and

the pump (q.v.) have been treated under their respective titles, but in this article the term will be considered as designating those machines which are operated by the element of pressure only, such as hydraulic lifts and water pressure engines.

The Hydraulic Lift, used in elevator service, is the simplest of all water motors. The direct-acting lift consists of a cylinder in which a ram or piston of equal length, with a cage attached to its upper end, works up and down. The level of the water supply must be necessarily above that of the maximum height through which the cage may be lifted, so that when the water is admitted to the cylinder at its lower end, the pressure forces the ram upward and thus lifts the cage. The descent of the ram is accomplished by closing the supply valve and opening the discharge valve, the ram descending by its own weight. As the weight of the ram is greater than necessary to bring down the cage, a part of that weight is balanced by a counterweight attached to the end of a chain that works over a pulley at the top of the lift and is connected to the cage. The most familiar examples are the high-speed hydraulic passenger elevators. They are operated by the pressure of water pumped into tanks situated on the roofs of the buildings in which they are installed, while the operating machinery is located in the basement. (See ELEVATORS). The hydraulic press and the hydraulic ram are devices operated practically under similar principles. In the former, the action depends upon the principle of hydrostatics that a pressure applied to any part of the surface of a liquid is transmitted in all directions and throughout the mass without diminution. For example, if a cylinder filled with water has a plunger one inch square working through one end and another 10 inches square working through the other end, and a pressure of one pound is exerted on the smaller plunger, this pressure will be transmitted to the larger plunger and be delivered by the latter in a multiplied amount equal to the square of its face area expressed in pounds. In this example that pressure would be 100 pounds. Such presses consist essentially of two cylinders connected by piping. The pressure is applied to the plunger of the smaller cylinder and the multiplied pressure is transmitted by that of the larger to the object to be raised or pressed. In construction they vary greatly with the purpose for which they are employed. Those used as hay, cotton and oil presses consist of four strong iron pillars arranged in the form of a square, which carry a cast-iron plate solidly attached to their tops. A similar casting is situated at the bottom of the pillars. Through a circular hole in the centre of the lower plate, a plunger carrying a square platen on its head works with an upward motion and presses the material placed between the platen and the under face of the top plate. In presses used for hydraulic forging, the cylinder and plunger are carried by the top plate, while the bottom plate carries the anvil. The plungers work downward in the act of pressing or hammering. They are made of various sizes and are generally provided with two pressure plungers and cylinders and they are adapted for purposes varying from the manufacture of revolver cartridge cases to the

forging of armor plate, guns and steamship shafts. Armor plate presses capable of exerting a pressure of 14,000 tons are in use, while 7,000-ton fluid compressors are employed in many of the larger steel manufacturing plants. A brief description of the construction and working of one of the last-named capacity will serve to illustrate the mammoth proportions and enormous power of these machines. It consists of an upper head weighing 120 tons carrying the plunger and a 135-ton base plate containing the hydraulic cylinder. These are supported and held in place by four vertical connecting columns each 50 feet long, and 19 inches in diameter. In operation, the molten metal is poured into a mold built up in sections and the mold is raised under a hydraulic pressure of 7,000 tons, while a plunger attached to the upper head bears down upon the fluid metal and compresses it.

**Hydraulic Ram.**—In the hydraulic ram the force of water flowing by gravity is utilized to raise a portion of its volume to a height above that of the source of supply. Two pipes are employed. The water in flowing through the main or drive pipe acquires sufficient momentum to close a valve at the foot of the pipe, and the water thus confined automatically opens another valve, partially fills an air chamber situated over the foot of the main pipe and compresses the air in it until the pressure within balances the column of water in the main pipe. Then the foot valve of the main pipe opens again and the action described is repeated. In the meantime, the pressure in the air chamber forces the water through a small service pipe leading out of its bottom, to the required height. See **HYDROSTATIC PRESS; HYDRAULIC RAM; POWER TRANSMISSION; PUMPS AND PUMPING MACHINERY.**

**Hydraulic Engines.**—In the hydraulic lifts or elevators, the admission and discharge valves are worked by hand at the will of the operator, but in the engines the mechanism actuates the valves automatically and periodically, thus converting the lift into a machine with a continuous action. Unlike the vertical water wheels and turbines, the efficiency of which depends upon the weight of a large body of water falling from a comparatively small height, the water engines work under the pressure of a small column of water descending from a considerable elevation. They are of three types—the “single action,” in which a piston working in a cylinder is moved upward by the pressure of the water, and downward by the weight of the piston itself; the “double action,” in which the cylinder is closed at the top as well as at the bottom, and the water admitted to it by supply pipes at those points, acts reciprocally on the piston from above and below; and the “rotary,” in which the water pressure acts on a revolving piston similar to that of a rotary steam-engine. Rotary engines may be of the single-acting or double-acting type, the advantage being with the former, since the pressure of the piston is always exerted on the crank pin in one direction and the dead centres are passed without knocking. Generally three single-acting cylinders formed in one casting are used in connection with a disc valve with segmental posts which pass over correspond-

ing apertures in the valve seating, during rotation and the engine will readily start in all positions. The first engine of this kind was constructed by Sir William Armstrong, who also subsequently designed one of the reciprocating pattern. Since then a great variety of hydraulic engines have been invented, the greater number of them being of the last-named type. (See **HYDRAULIC ENGINE**). They have a wide field of usefulness, especially as auxiliary motors for driving small machinery such as hoists, swing-bridges, capstans, cranes, winches, etc. The employment of superheated water motors is one of the latest developments in the methods for railroad traction. In the earlier forms of engines operated by superheated water, the storage tank being charged with water at a temperature corresponding to several hundred pounds of pressure, only the steam from the water was utilized in the cylinders of the motor, in a manner similar to the utilization of steam from the boiler of a locomotive engine by expansion in its cylinders. Their operation was based upon the relation of temperature and pressure to the vaporization of liquids and the steam was drawn off from its point of formation at the top of the storage tank to the cylinders. Under these conditions, with each revolution the new steam was supplied by water which boiled at continually lower and lower pressures and reduced temperatures, until the pressure fell to a point at which it was not available for use in the motor; and only about one-ninth of the energy of the heated water was actually used in the cylinders. W. E. Prall of Washington, D. C., suggested the utilization of the power in the storage tank by withdrawing the superheated water directly from the bottom of the tank instead of steam from the top and allowing the water thus withdrawn to expand into steam within the cylinders of the engine itself. In the latest motors, this is accomplished by a generator composed of a nest of tubes coupled into manifolds at the top and bottom. The working pressure is about 700 pounds to the square inch and the water is drawn off from the generator into three insulated storage tanks with a total capacity of 7,000 pounds, carried beneath the car. From the bottom of the tanks the water is delivered through three Tappet valves provided with screw and nut adjustment to regulate the amount of feed. In operation, under the decreasing pressure caused by the movement of the piston through its stroke, the water resolves into steam in a continuous series of flashes, the steam and the unevaporated portion of the water from the high-pressure cylinders passing out through the ports in its bottom and draining off through valves in the lower face of the valve chest. The exhaust steam from the high-pressure cylinder passes in the usual way to the low-pressure cylinder and is eventually exhausted into the atmosphere. A car equipped with two compound engines and three tanks charged with water at a pressure of 700 pounds to the square inch and a corresponding temperature of 500° is capable of running 40 miles at a speed of from 30 to 40 miles an hour.

**WATER-PLANTAIN**, an aquatic or marsh herb of the genus *Alisma*, family *Alismaceae*, of which *Sagittaria* (q.v.) is also a member. The plant most commonly known as water-plantain is that found also in Europe and Asia (*Alisma plantago aquatica*), which grows in mud or shallow water. It has a circle of radical long-petioled leaves, ribbed ovate and strongly resembling those of the common plantain. The scape, which is usually solitary, branches verticillately, and forms a large, open pyramidal, flowing panicle; the blossoms are very small, white or rose-colored and have their parts in threes.

**WATER POWER.** Water power is derived from the conversion of the energy of falling water into mechanical work. If a volume of water having a weight  $w$  in pounds is situated at a height  $h$  in feet above a plane of reference, it possesses a potential energy  $w \times h$  in foot pounds, all of which can be converted into kinetic energy by allowing the water to fall through the height  $h$ . If the water in falling passes through a suitable hydraulic motor, most of its potential energy can be converted into useful mechanical work, in which case the water will reach the bottom of the fall with little or no energy remaining, instead of having its full energy remaining in kinetic form, as it would do if it fell freely and unrestricted. In practice, water power is usually derived from running streams, and the amount of power is expressed in terms of the rate at which energy is supplied to or derived from the hydraulic motor. The ratio of the rate at which energy is derived from an hydraulic motor to that at which it is supplied to the motor is called the "efficiency" of the motor. The amount of power may be expressed in terms of the rate at which energy is supplied, or the rate at which mechanical work can be performed by the motor. The former is called the "theoretical power" of the water or stream supplying the motor.

One horse power, as defined by Watt, represents energy sufficient to raise a weight of 33,000 pounds one foot high per minute, or in other words, 33,000 foot-pounds per minute, or 550 foot-pounds per second. Fresh water weighs 62.42 pounds per cubic foot, hence the theoretical horse power of a constant stream of water, flowing in a volume of  $q$  cubic feet per second, and falling through a height of  $h$  feet, is equivalent to

$$\frac{62.42 \times q \times h}{550} \text{ horse power.}$$

This reduces to the simple rule—  
Theoretical horse power of water =

$$0.1135 \times q \times h.$$

The output or derived power of an hydraulic motor, or of a water power, is the product of the theoretical power multiplied by the efficiency expressed as a decimal, or if the effi-

ciency is  $E$ , then the mechanical or brake horse power is equal to

$$0.1135 \times q \times h \times E.$$

Efficiency may be considered with reference to the hydraulic motor alone, or with reference to the entire power plant, including allowances for losses of power in electric generators and other equipment in the case of hydro-electric plants. If used in the latter sense it is termed "over-all efficiency," and the theoretical horse power, multiplied by the over-all efficiency, represents the net rate of power output by the plant or power development.

Water power ranks with mines and the soil as one of the greatest natural sources of wealth. Coal and oil supply at present the greater portion of the fuel and energy used in the world, but this supply is exhaustible. The soil fosters organic growth, which is capable of supplying energy resources chiefly in the forms of wood and of alcoholic fuels. These sources of energy, like water power, are perpetual, but are at present relatively much less important.

Machines or organisms through the operation of which useful mechanical work is derived from natural sources of energy are called "prime movers." There are organic or living prime movers which derive useful mechanical work from the latent energy contained in the food they eat. Men and horses are found to be relatively inefficient as prime movers. The human body is capable of yielding back through muscular work only about one-fifth of the available energy supplied to it as food. Another class of prime movers consumes fuel and converts its potential energy into kinetic energy by means of steam, gas and oil engines. Both the preceding classes may be considered as fuel engines. They derive energy from highly organized compounds which have originated in life processes. These are broken down into simpler compounds by the processes of digestion or combustion, and in accordance with a rule of nature, they give up a supply of stored energy as they are disintegrated. The supply of power from chemical reduction being dependent upon life processes, can be renewed by a perpetuation of life, but unfortunately fuel consumption at the present time greatly exceeds the rate of renewal, and we are mainly dependent on the great storehouse of latent energy given us as a legacy from past ages in the form of coal, oil and gas. The power consumption at the present day, if derived from wood alone, would exhaust our timber supply in a few years. In the early days of railroads, wood was used as fuel in locomotives. Few of us realize the extent to which the forests were devastated to supply that need.

Prime movers of another or third general class derive their energy more directly from the sun and operate by means of the winds, waves and tides. This class includes solar engines that concentrate and utilize the sun's heat directly. It also includes wind mills. Water wheels of all kinds belong to this general class. The source of their power is the sun's heat, operating through the hydrologic cycle of precipitation, evaporation and run off. Vapor evaporating from the seas and lands is condensed in the upper air, and falls again on the uplands as rain, running in streams and rivers down the hillsides and valleys to the lakes and seas, and again evaporated, is kept in a perpetual cycle of

change by the opposing forces of the energy of the sun's heat and the earth's gravity. It is the sun which supplies the power to overcome gravitation and lift the water to a height from which in falling it drives the water wheel.

runner. The hydraulic turbine is usually encased or submerged in a flume, and is often "out of sight, and out of mind," to the extent that it lubricates itself, and frequently does not receive or require direct attention for years of operation.

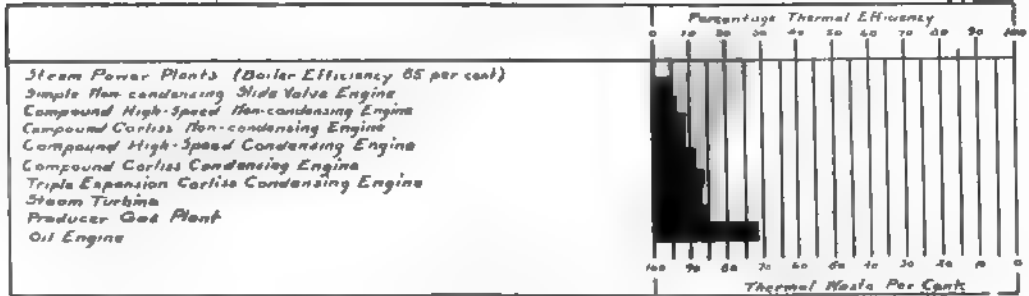

FIG. 1.—Comparative Efficiencies of Fuel Motors.

The usual efficiencies of different types of fuel engines are shown graphically by Fig. 1. The average efficiency of fuel engines in use at the present time, of all kinds, including gasoline and steam engines, steam turbines and locomotives, is probably about 10 per cent.

A water-power development consists essentially of a turbine or water wheel with adequate means of supplying the water and regulating the supply. Types and methods of water-power development are so closely related to types of water wheels that it is necessary to give

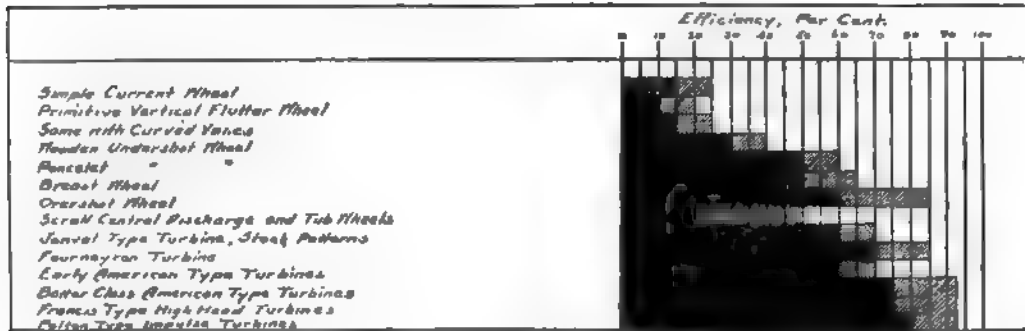

FIG. 2.—Comparative Efficiencies of Water Motors.

Fig. 2 shows the average efficiency (solid black) and the best efficiency (shaded) ordinarily obtained from various types of hydraulic motors. This diagram shows, for purposes of comparison, the efficiency of various early and obsolete types of water wheels, such as current, flutter and central discharge wheels. Even these were more efficient than the best fuel engines. At the present time practically all water wheels in use are of one or the other of the last three types shown on Fig. 2. These have efficiencies ranging from 70 to 93 per cent. The great efficiency of hydraulic turbines as compared with other prime movers is strikingly illustrated by the fact that if it were possible to replace all fuel engines now in use by some improved type, having an efficiency equal to that of the hydraulic turbine the effect would be the same as if the existing supply of coal in the world was increased at least seven times. Not only is a developed water power the most efficient means of converting natural energy into mechanical work, but the hydraulic turbine is the simplest of all prime movers. Such a water wheel usually contains only one continuously moving part—the

here some description of the latter. A water wheel is a hydraulic motor that operates continuously by rotation in the same direction. A canal lock lifting a boat is a water motor but is not a water wheel. A water wheel usually consists of various parts, of which the most important is the runner, or moving part. A runner is usually divided into various compartments into, or through which, the water flows. These compartments are properly called buckets. The word bucket is often used incorrectly to describe the vanes or partition walls which form part of the boundary of the bucket. It is better to describe the partition walls between adjacent buckets as vanes. It is often convenient to speak of the passage through or into which the water flows, and these passages are sometimes themselves called buckets, but may be more properly referred to as bucket passages. As stated above, the buckets are separated by vanes, which form the boundary walls on two sides of each bucket. The boundary walls on the remaining two sides are usually formed by the crowns. The compartments through which the water flows into the buckets are properly termed chutes or guide

chutes. The passage through a chute may be conveniently called a guide passage, and the partition walls between adjacent chutes are properly termed guide vanes. Usually a water wheel of the turbine type is enclosed in a case, of which the guide chutes form a part, and

spoken of as a case, but inasmuch as the wheel proper has a case which is placed inside the penstock, it is better to make the distinction of meaning given above.

Fig 3 shows a phantom view of a modern hydraulic turbine, giving the names and relative locations of different parts. The accompanying table contains a classification of water wheels. Further descriptions of water wheels herein will be limited to the hydraulic turbine, which is practically the only type of hydraulic motor now in extensive use, excepting a limited number of impulse water wheels of the Pelton type.

FIG. 3.—Turbine Type of Water Wheel. Phantom view of wheel-case.

within which the runner is placed. As a rule, the case also contains gates for regulating the water supply. These may be classified as cylinder gates, register gates and wicket or pivot gates. Turbines are set in compartments called penstocks to which the water is led by means of a flume. The words penstock and flume are often used with the meanings here given transposed. A penstock of sheet iron or steel is often

The word turbine, meaning primarily a "wheel that revolves" does not of itself distinguish the class of water motors to which it is commonly applied. The word turbine appears to have been first applied to a water wheel by Burdin in 1825. Fourneyron, a pupil of Burdin, perfected the outward-flow wheel, and his use of the term turbine as describing such wheels led to its general adoption to distinguish water wheels operating by combined action and receiving their water supply to all the buckets simultaneously. We find the word turbine variously defined by different authors. Weisbach includes impulse wheels in the class of turbines. Bjorling distinguishes a turbine from a water wheel in that it takes its water supply at the centre or bottom of the fall, while a water wheel takes water from the top of the fall. Bodner says a turbine may be defined as a water wheel in which a motion of the water relative to the buckets is essential. We also find a turbine defined as a water wheel having buckets which the water flows through instead of in and out at the same opening, as in the case of an overshot or impulse wheel. Again a turbine is defined as a water wheel in which the buckets are entirely filled instead of being partially filled as in the case of a water wheel or impulse wheel. The hydraulic turbine in all its various forms is practically a development of the 19th century, and the modern high speed large capacity hydraulic turbine has been

CLASSIFICATION OF ROTARY HYDRAULIC MOTORS

MODE OF RECEIVING WATER ON RUNNER	Place of receiving water on runner	Action of water at full capacity	General direction of flow in wheel relative to runner	Usual designation of water wheel
At one or more points on circumference but not usually on entire circumference.	Near summit of runner on horizontal axis.	Gravity	Circumferentially downward	Overshot and pitchback

**WATER POWER**

**Fig. 4 The 10,500 Horse Power Turbine of the Shawinigan Water and Power Company, Quebec, Canada**

WATER POWER

Fig. 3 Hydro-Electric Plant of the Mengemor Company, Spain

evolved from a somewhat crude prototype, mainly within the last 40 years. In the early part of the 19th century, parallel flow or Jonval turbines, and outward flow, or Fourneyron turbines, both French inventions, were largely used. In the former the water flowed through the turbine runner in a direction generally parallel with the axis. In the latter the water flowed outward more or less radially through the runner. These simple types of hydraulic turbines were capable of application only to relatively small capacities and low speeds. Then came the development in America of the inward flow type of turbine. This was the work of no one inventor, although Samuel B. Howd of Geneva, N. Y., patented such a turbine in 1836, which closely resembles the most modern types in its principle of operation. While more compact and giving a higher speed than the French turbine, it was still a wheel of small capacity. James B. Francis of Lowell improved the mechanical construction and efficiency of the Howd wheel, and further developments were made by Swain and others. Even before the advent of hydro-electric power developments and transmission, there came a demand for water wheels of higher speed and greater capacity than could then be supplied. Probably the greatest achievement of any one man in advancing the development of the hydraulic turbine was that of John B. McCormick of Indiana County, Pa. About 1870 he found that by extending the bucket vanes of an inward flow turbine downward and outward, making them ladle or spoon shaped, he was able to greatly increase the outlet openings of a turbine of a given diameter. At the same time the length or the depth of the inlet openings was proportionately increased, thus greatly increasing the capacity without increasing the diameter of the runner. Since the speed of a turbine decreases as the diameter increases, he thus produced a turbine of much greater capacity than any heretofore available without reducing the speed. It was also found that the use of curved vanes, providing for downward and outward flow, as well as inward flow, through the runner, increased the efficiency, since the water left the wheel in a direction opposite to that of the motion of the runner, and so dropped away from the runner with very little absolute velocity.

McCormick's designs were, however, arbitrary, and each size or pattern was worked out by long and costly experimentation. While the theory of the hydraulic turbine had been developed mathematically many years before, it had never been successfully applied in practice to the design of turbines to meet specific conditions until after the advent of hydro-electric power transmission. The next step in advance consisted in the modification of the combined flow or McCormick turbine, largely by means of theoretical deductions so as to adapt it to speeds, capacities and other conditions somewhat different from those for which the experimental designs were made. This process started in Europe, especially in Switzerland, where it was first applied to outward flow or Fourneyron turbines, exemplified by the Swiss turbines installed in the Niagara power development of 1895. Scientific methods of design were soon extended to inward and combined flow turbines, chiefly in the United States. until at the present time,

combined inflow, or so-called Francis type turbines are produced, not only of enormous capacity, high efficiency and speed, but of design so nicely adjusted as to give in practice almost precisely the required or pre-determined speed, power and efficiency to meet any desired condition, yet the form of runner and principle of its operation are almost precisely as McCormick left it.

The essentials of a modern hydraulic turbine as illustrated by Fig. 3, include: (a) The runner; (b) the guide vanes, which are usually pivoted, so the openings between them can be opened or shut, thus forming gates; (c) the case, which supports the guides and gates, and has bearings which support the runner.

In Fig. 4 the case includes a spiral channel surrounding the gates and runner, for the purpose of conducting water to all parts of the circumference of the wheel at uniform velocity. The spiral chute is often omitted from the case, especially where the turbines operate under relatively low heads. In such cases, it is frequently replaced by a spirally formed compartment of concrete, forming a wheel pit, in which the turbine is set. The pivoted, or as they are called, "Fincke" gates, are an adaptation of a similar contrivance which was used on some of the earlier American stock pattern turbines. The spiral chute is an adaptation of a similar form of case, used on primitive wooden or iron central discharge turbines. The principal desiderata of an hydraulic turbine are: (1) High efficiency; (2) good efficiency when operating at part gate or partial capacity; (3) compactness; (4) high speed; (5) adaptability to speed regulation. These results are all attained in a remarkable degree in the type of turbine illustrated in Fig. 4.

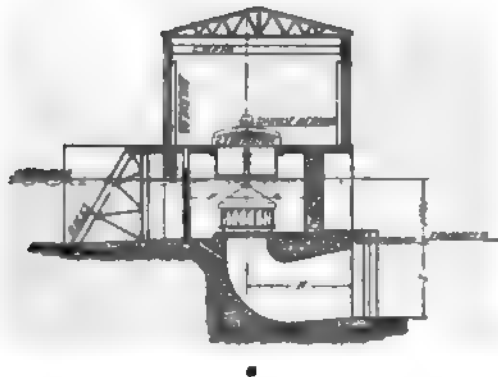

Power developments are generally classified as low medium and high head installations. The type of the turbine and the mode in which it is set in the flume depend largely upon the head, and this governs in a general way the entire layout of the power development.

The essential features of a modern water-power development comprise: (1) A dam to impound the water. The dam may be of logs, sawn timbers, stone or concrete, and sometimes of steel or a combination of one or more of these with earth embankments. It is usually provided with a spillway or gates. (2) Head gates to control the water to be diverted, and trash racks, the latter to exclude ice and débris. (3) A conduit which may be either an open canal, an open timber or metal flume or head race, or a closed pipe of wood or steel. A long closed flume is usually connected to a surge tank near its downstream end. (4) A wheel pit (if open) or a penstock (if closed) containing the turbine or turbines. (5) The turbine itself with its runner, guides, gates and casing. (6) A draft tube to convey the water from the wheel to the tail race. (7) A tail race, which is usually an open channel, to convey the water back to the natural stream. (8) A speed governor.

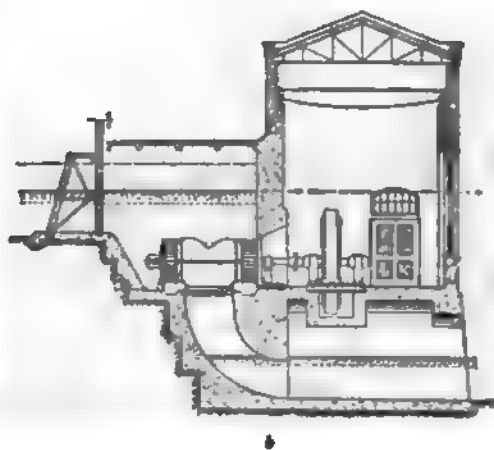

Power developments may be classified according to the manner in which a sufficiently concentrated fall or head is obtained, as (1) "cascade" developments, and (2) "canal" developments.

Fig. 5 illustrates various modes of setting hydraulic turbines in power plants. Fig. 5-a shows a vertical turbine in an open concrete flume. This mode of setting is most generally used for relatively low head developments. The wheel compartment is often spiral in form. Fig. 5-b shows horizontal turbines in an open rectangular flume. In Fig. 5-b there are two turbines or runners combined in a single unit, discharging into a common compartment between them, called the draft chest. The size of a tur-

the stream instead of wasting its energy in eddies and swirls and friction on the rough stream bed, flows smoothly and slowly through the pond to the dam with very little loss of power by friction. In a cascade development, the power plant is located immediately downstream from the dam or natural fall. Where a canal is used to concentrate the fall it is usually made uni-

bine of a given capacity generally varies somewhat inversely as the speed of the turbine. By the use of two runners forming a single unit, as in Fig. 5-b, the capacity of the power unit is doubled without decreasing the speed, or in other words, a given power is obtained at a much higher speed than would result from the use of the single turbine runner of equal capacity. Fig. 5-c shows a vertical turbine with a closed spiral concrete penstock. This type is often used for medium heads. Fig. 5-d shows a horizontal turbine, with a spiral supply chute combined with

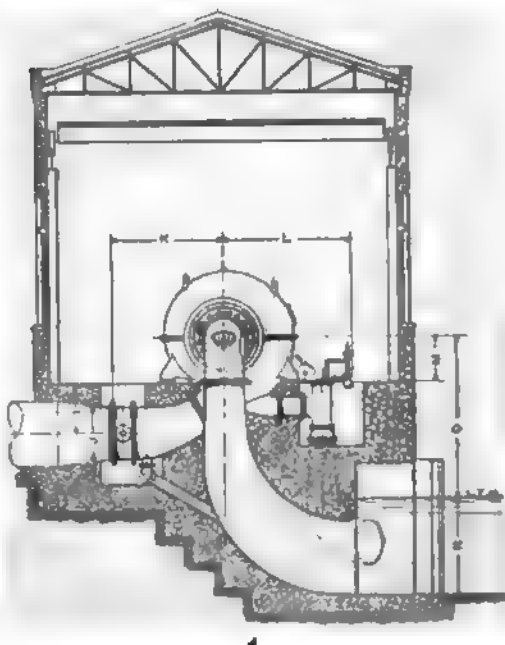

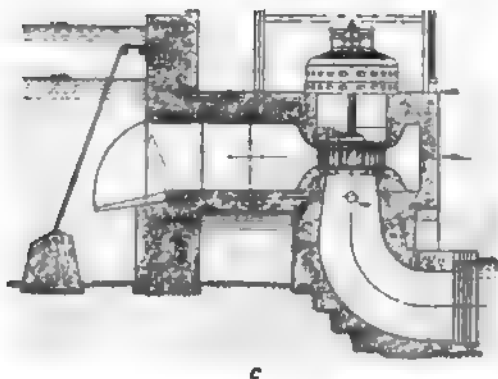

FIG. 5.—Usual Arrangements of Power House and Hydraulic Turbines.

the turbine case. This type is most commonly used for high head power developments.

A sufficiently concentrated fall for power development may occur in a stream naturally, or it may be created artificially. Fall is obtained artificially by (1) a dam, or (2) a canal or conduit, or (3) by both combined. Where a dam is built the fall which naturally occurred in the stream from the dam up to the head of the pond which it forms is concentrated at the dam, and

form and smooth as possible with just enough grade to convey the required volume of water to the power house slowly and smoothly. The stream having a much steeper grade than the canal, the difference of level in the canal and stream, or, in other words the head, progressively increases proceeding downstream. Where the water is conveyed from the dam to the power house through a closed conduit, the principle is the same as where a canal is used,

for although the conduit may lie down near stream level, the water would rise in a vertical open pipe, connected to the conduit at any point, to a height nearly equal to the level at the entrance to the conduit. The difference between the height of the water at the source and the height to which it would rise in such a pipe is the head lost by friction in the conduit. In the earlier days of water-power development in the United States it was considered impracticable to utilize a head of more than about 30 feet on a single turbine. Accordingly, where the fall in a stream was greater than this at a given location, the total fall was subdivided between different canals, and the water drawn from the uppermost level supplied turbines which discharged into the second or next lower level, etc. This type of canal development was successfully utilized at Holyoke, Mass., Cohoes, N. Y., and elsewhere, but it often happened that mills on lower levels did not require the full quantity of water discharged from the upper levels, and a large waste would occur. One of the results which is being brought about by modern advanced methods of power development is the substitution of single hydro-electric stations for such canal systems, thus conserving a considerable portion of the available power.

Turbines are usually set at some height, never more than 25 feet, above the bottom of the fall from which they derive their power. The utilization of the power of the water in falling through a height equal to the distance from the centre of the turbine down to the level of the tailrace is effected by means of the draft tube. The water in falling through the draft tube creates a suction head, which increases the pressure or power of the water operating the turbine exactly as if the turbine were placed at the foot of the fall, thus rendering the full use of the head practicable. Placing the turbine above the tail water has many advantages; among others electrical generators can be directly connected to horizontal turbines so placed without danger of being flooded during high water. Theory requires that in order to utilize the power of a stream of water to the fullest degree, the water must be discharged back into the stream after its use, with the least possible velocity. It is never possible to discharge the water from a turbine wholly without velocity. The velocity of discharge can be much further reduced by passing the water through a gradually expanding draft tube after it leaves the turbine. The velocity of the water entering the draft tube is mostly converted back into draft head, which in turn increases the effective head and power of the turbine.

One of the most difficult and at the same time the most important factors in successful water power development for the purpose of generating electricity is the matter of speed regulation.

In many hydro-electric plants, sudden and large changes in load on the hydraulic turbine, or in the amount of power required, take place. To generate electricity for commercial use, the voltage of the current must remain practically constant. In order that this shall be the case, the speed at which the generator is driven by the hydraulic turbine must be regulated and maintained as nearly constant as possible. If the gates regulating the supply of water to the turbine were set at a constant or fixed position,

then each time that a change in load to the turbine occurs, there would be a corresponding change in the speed of the turbine and the generator which it drives. The problem of regulating the speed of an hydro-electric power unit is much more difficult than that of regulating a steam-engine or steam-turbine driven electric generator, for a variety of reasons.

Steam is a highly expansive elastic fluid. In order to regulate the speed of the steam engine, it is only necessary to partially open or close the ports or valves admitting steam to the engine cylinder. This is accomplished in plain slide valve engines by the familiar fly-ball governor, and in more advanced types of steam engines by closely related mechanisms. In order to regulate the speed of an hydraulic turbine with changing load, it is necessary to open or close the turbine gates. The weight of these gates and other connected parts which must be moved is enormously greater than the weight of the valves to be moved in regulating a steam engine. Thus the problem of quickly overcoming the inertia of heavy weights is involved. In the case of the steam engine, the steam pressure at the boiler is usually nearly constant. In the case of an hydraulic turbine, the head operating the turbine may vary within relatively wide limits at different seasons of the year. Thus when the head is reduced by back-water or otherwise, the gate openings must be wider to maintain a given load and speed than at other times. In hydro-electric plants supplied with water by means of closed conduits or flumes, especially if the head is high, sudden reduction in the gate opening of the turbine produces a pressure wave in the penstock similar to the water hammer effect produced when house faucets under considerable pressure are suddenly closed. This pressure wave tends to produce a sudden large increase in the head and pressure, and consequent overspeeding of the turbine at the instant when the gates are closed, or shortly after. This difficulty does not exist in the case of steam engine regulation. These problems have been solved by the use of modern governors for water wheels, to such an extent that the degree of speed regulation obtainable in hydro-electric plants closely approximates that attained in the best of steam driven power stations. The principle of operation of a water wheel governor is essentially the same as that of a steam governor. An incipient change of speed operating on a pair of fly-balls similar to those of a steam engine governor operates what is known as a pilot valve. This is a small valve, easily moved, and consequently sensitive to changes of speed, which admits oil under high pressure to a valve or system of valves known as the "relay." Oil under high pressure, flowing through the secondary valves, actuates an hydraulic piston, which is articulated to the water wheel gates. Thus the work of opening or closing the gates is accomplished by oil under high pressure from an accumulator, which is kept constantly supplied by means of an auxiliary pump. Another important feature of a water wheel governor is the compensator. If controlled by the fly-balls alone, the opening or closing of gates could take place only as rapidly as the speed changes. In that event, speed regulation for hydraulic turbines would be relatively slow and inefficient, furthermore its value might be

largely vitiated by the effect of surges. The purpose of the compensator is to immediately set the governor in operation approximately to the full change of gate opening which will be required for a given change of speed or load without waiting until the full change of load or speed occurs. Governors with compensators have been developed to such a degree of perfection that they will anticipate with but small error the total effect of a sudden change in load on the generator almost the instant that the change in load and resulting change in speed begins to take place. Slight errors in the first adjustment are quickly corrected by successive smaller movements of the governor mechanism, as the gate openings become adjusted to the new load conditions.

Pondage and storage may be distinguished in that the former is derived directly from a pond formed by the dam supplying the power plant. It is usually used only for the purpose of supplying a quantity of water greater than the average flow of the stream for the day, during hours when the load or demand for power is maximum. The pond is then allowed to refill during hours of the day when the supply exceeds the demand. When such a pond is drawn down to any degree to supply power, the available head is accordingly reduced, and there is generally an economic limit of the amount of the draft from pondage, since the drawing down of the pond to a greater extent reduces the head to such a degree that the power output is not increased by any further

FIG. 6.—Modern Water Wheel Governor.

Fig. 6 illustrates a typical water wheel governor or actuator of the oil pressure relay compensating type. Such an apparatus is almost human in its operation, in apparently anticipating pending load changes, the moment they begin, and correcting the gate opening in advance of the complete load change so as to maintain a constant speed.

Water power which is available continuously, or nearly so, is called primary or firm power. The amount of primary power which a given water power plant can produce is measured by the minimum flow of the stream, either natural or as regulated by storage. Power which can be supplied only part of the year, when the flow of the stream is sufficient to produce it, is called secondary or surplus power. Primary power brings the higher price of the two in the market per horse-power year, often about double that of surplus power. The amount of power available at a given location from a natural variable stream may be increased by the use of pondage, or storage, or both.

Storage, on the other hand, is a term usually applied where water which is not otherwise usable,—that is, waters mainly derived from floods or stream flows in excess of the power plant capacities, are stored and held in reserve by natural lakes or artificial reservoirs. Such stored waters are used to make good part of the deficiency in supply of a natural stream during the low water periods. Storage thus increases the average available output of the plant, regardless of the mode of operation, whereas pondage only increases the available output when the demand for power varies from hour to hour during the day.

In the early days of water power development, water power plant capacities were usually made a little greater than the dry weather capacities of the streams supplying them. For example, a common practice was to make a plant capacity equal to the flow of the stream during the third driest month, in other words, the stream would supply the full capacity of the water power plant during nine months of the

quantities of power which could be produced by the entire flow of the stream are determined. In Fig. 7 these quantities are plotted as ordinates in terms of percentages of time during which the flow of the stream or power available

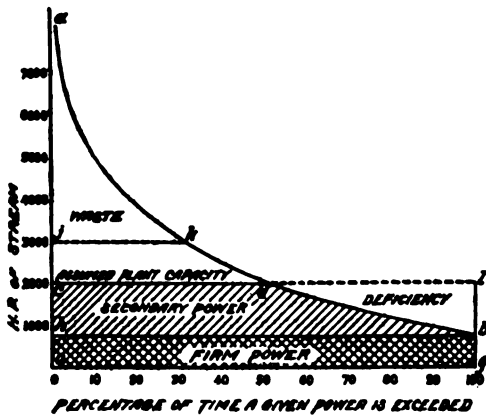

FIG. 7.— Water Power Duration Diagram for an Unregulated Stream.

exceeds a given quantity. These time percentages are shown by the scale at the bottom of the diagram. The total area of the diagram *o-a-b-g* represents the aggregate volume of power available during the year. If a plant having a capacity of say 2,000 horse power is contemplated, then the area of the diagram *o-c-d-b-g* lying below the line *c-d*, corresponding to 2,000 horse power, represents the aggregate average yearly volume of power which would be produced by such a plant, while the area *a-c-d* lying above the plant capacity line represents the volume of power which would be wasted in excess flow or floods. The quantity of firm or primary power which could be produced is represented by the rectangular area *h-b-g-o* lying below the lowest point *b* on the power duration curve, while the area *h-c-d-b* represents the aggregate amount of secondary

horse power, as indicated by the line *j-k*, the quantity of firm power would remain the same as before, and only the secondary power would be increased. This in turn would not be increased by so great a proportion as the size and consequent cost of the power plant.

These conditions go to fix and determine the most economical size of water-power installation which can be installed in a given case. Fig. 8 illustrates the effect of a partial regulation of the same stream at the same power site by means of storage. The power duration curve as regulated by storage is represented by the line *a-d-m*. The average power output is increased by an amount represented by the shaded area *d-b-m* for a plant of 2,000 horse-power capacity. The firm power is increased to a greater degree, being represented in this instance by the area *m-n-o-g*.

One of the apparent advantages of storage is that the stored water can be utilized over and over again by successive plants located on the stream below the storage reservoir. There are, however, certain disadvantages attendant on the utilization of storage which reduce its efficiency for power purposes. As a rule where a storage reservoir is located at some distance upstream from a water-power development, it is not feasible to discharge the stored water in such a manner as to regulate the stream during only the working hours, so that if a power plant below the reservoir operates during certain hours of the day only, and does not have sufficient pondage to regulate the flow for a 24-hour period, then the storage which is let out of a reservoir at some point upstream continuously during the dry period, will partially go to waste, the waste in extreme cases, for plants operating 10 hours a day without pondage, being as much as seven-twelfths of the entire volume of stored water released. A storage reservoir, therefore, effects the greatest benefit on streams where power plants are located which operate uniformly and continuously or have extensive pondage in immediate connection with the power developments. The quantity of water reaching a power plant located at some distance downstream from a storage reservoir is the sum of the quantity of water discharged at the reservoir and the natural inflow to the stream channel between the reservoir and the power plant. As the distance from the storage reservoir to the power plant increases, the ratio of the latter to the former also increases, with the result that proceeding downstream from the storage reservoir the degree of regulation afforded thereby progressively decreases.

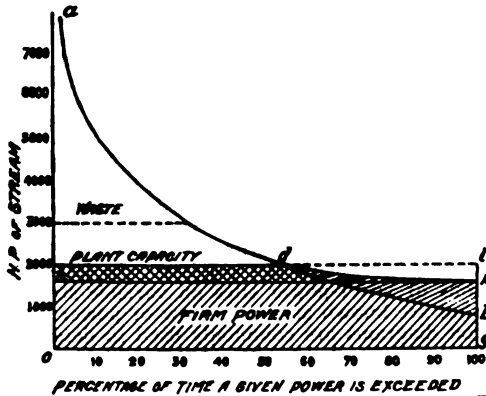

FIG. 8.— Water Power Duration Diagram with Partial Stream Regulation by Storage.

power which could be produced by the given plant. The area *d-l-b* represents the deficiency which must be made up by steam or other auxiliary power in order to produce a constant output of 2,000 horse power of firm power. If the plant capacity was increased to say 3,000

The first hydro-electric central station in the United States was installed at Appleton, Wis., in 1882. The use of hydro-electric power for lighting advanced rapidly during the 80's, this advance following quickly the invention of the incandescent lamp by Edison in 1879. While there were some previous experiments carried out, the first large scale successful long distance power transmission was that from Lauffen to Frankfort, completed in 1891, by which 110 horse power was transmitted a distance of 112 miles at 12,000 volts. This provided the initial stimulus for extensive hydro-electric power development. Prior to that date, water power was not much used for the generation of electric

current unless the water power happened to be located very near the site where the current was to be used.

The growth of hydro-electric power development has taken place mainly along natural economic lines. In general water powers near large industrial centres were developed first, and of these, those involving the lowest primary investment have been given preference; furthermore, the first water power developed in a locality has generally been that having a size suited to the demands of the immediate future. Thus it happens that some of the very largest water powers, as well as numerous smaller ones, have thus far remained undeveloped. The necessity of developing powers of a size suited to the existing market conditions at the time of development is emphasized by the fact that many of the larger hydro-electric developments in the eastern United States passed through bankruptcy, but are now operating successfully. The cause of the financial difficulties was in general that it took too much time to build up an adequate market for the output of a power larger than the immediate demand, and during this time the revenue was insufficient to meet interest payments and other fixed charges on the large investment.

There has been a progressive advance both in the modes and extent of utilization of electric power, especially hydro-electric power. Originally, its principal uses were for street lighting and street railway traction. In eastern United States good roads and automobiles have lessened the latter demand, although in the Pacific Coast States electric railroads afford the principal means of transport between important commercial centres,—coal is more costly—and a large proportion of the hydro-electric power produced is used for traction purposes. In the meantime electric lighting has been greatly increased in efficiency. The amount of current required per candle power is much less than formerly. This has stimulated the use of electricity for lighting purposes, and the demand for electric current for ornamental public lighting, and for domestic and commercial lighting and advertising, is rapidly increasing, especially where current produced by water power can be supplied cheaply.

The introduction of hydro-electric power for manufacturing purposes took place more slowly than its use for lighting and traction. At the start almost every manufactory had its own steam or water-power plant, with a complicated system of shafting and belting to drive individual machines. To replace this system by the use of motor drives for individual machines, equipment representing a large investment must be discarded. The development of highly efficient variable speed motors, with large initial capacity for starting, combined with the many advantages of direct electric drives for each machine, and the increasing cost of coal and labor, have brought about within the past decade a gradual introduction of the use of hydro-electric current for power in manufacturing. This gives promise of rapid extension in the immediate future. Not infrequently manufacturing plants owning water powers have installed electric generators, and have also connected their plants with the transmission lines of commercial electric companies. If, as usually happens on variable streams, the

water power alone is insufficient to supply all the power required by the manufactory during low water periods, the current is then purchased from the distributing company to make good the deficiency, instead of generating auxiliary power by steam.

When the stream supplies more current than is required, or at night or other times when the manufacturing plant is shut down, the water power which would otherwise go to waste is converted into electric current, and this is turned on to the commercial distributing lines, thus effecting an interchange of power advantageous to both parties. The use of inter-connecting distribution lines, or of a common distribution system, supplied by several hydro-electric power plants owned by different companies or individuals, with an agreement for interchange of surplus power, is now being accomplished in several instances. This procedure bids fair to stimulate the electrical development or re-development of numerous smaller water powers going to waste through non-use or abandonment, or which are now inefficiently used mechanically for manufacturing purposes.

Fixed charges on initial investments form a large item—amounting often to about one-half the total cost—of hydro-electric power production. As a rule the initial cost of hydro-electric power development of small water powers is relatively high, often prohibitively so. This is especially likely to be the case where the investment includes the cost of transmission lines to market the output. Where a common distribution system is used, a small water power located near a transmission line may sometimes be developed, and its output turned upon the existing transmission line at the requisite phase, voltage and frequency. By thus operating "in parallel," as it is called, the construction of costly transmission lines for small water powers may be avoided in such cases, and a market found for their output. A further stimulus to the use of hydro-electric power in manufacturing is afforded by the increased cost of coal subsequent to the Great World War.

In certain lines of manufacture, non-constant power can be used to advantage, as for example in the grinding of wood pulp for printing paper, a process which consumes relatively large quantities of power, commonly about 75 to 100 horse power per ton of product per day. Such industries afford a market for a large quantity of secondary power from hydro-electric stations.

Electro-chemical industries require large and constantly increasing quantities of electric current, which because of its cheapness compared with steam-generated current, is almost wholly produced by water power. Recently practicable methods of fixation of nitrogen from the atmosphere have been developed. The product is used in the manufacture of explosives, in other chemical industries, and especially as a means of the nitrification and consequent fertilization or otherwise weak, worn-out or sterile soils. The demand for nitrogen compounds for agricultural fertilizers is enormous. Their production from the atmosphere requires the use of large quantities of electric current. Under present conditions the fixation of nitrogen on a commercial basis for agricultural use can only be accomplished where hydro-electric power is available in large quantities at extremely low cost. This is obtained in some instances, in

Scandinavia in particular, and affords a prospective means of utilization of large water powers remote from commercial manufacturing centres.

At the present time, hydro-electric power developments range in size from those of a few horse power, supplying individual farms or small industries, to plants of 100,000 horse power or more, as at Keokuk, Cedar Rapids and Niagara Falls. The number of existing small water powers of 1,000 horse-power capacity or less which are undeveloped greatly exceeds the number of large water powers, but by far the larger proportion of the total output of hydro-electric current is produced by medium-sized plants of 1,000 to 20,000 horse-power capacity, owing to the fact that these have been found to meet more generally the requirements of commercial feasibility for existing market conditions.

Hydro-electric power plants include so wide a variety of natural conditions, types of equipment and methods of development as to be difficult of typical illustration. They range in heads or falls utilized from a few feet to several thousand feet—in voltage the current ranges from a few hundred volts to 150,000 volts—and in distance of transmission of the output the range is from zero to several hundred miles. Certain features are, however, more or less common to nearly all hydro-electric power developments, and these are illustrated by the following examples: Fig. 9 gives an external view, and also a view of the interior, of an hydro-electric power station of the Mengemor Company, Spain. This is a typical cascade development, in that the fall is created by a dam which also provides pondage, and the power station is located immediately adjacent to the dam; Fig. 10 shows an external view, and also a view of one of the turbines and generators, of the hydro-electric power station of the city of Tokio, Japan. This is a high head development of the canal type. Water is brought to the top of the bluff from the Katsura River, which has its source in Mount Fuji, by means of a canal, from which it is conveyed to the power station through steel pipe conduits. The turbines are of phosphor bronze, of 4,500 horse power each, and operate under a head of 315 feet.

Fig. 11 shows the power station and pipe lines supplying it used to generate electricity for the city of Bellinzona, Switzerland. This is a very high head development, in which water wheels of the impulse, or Pelton type, are used, as shown in Fig. 11-b. The head or fall operating the water wheels is 1,132 feet. The water is brought down from the source of supply above the crest of the mountain through the small pipe line shown in the background in Fig. 11-a.

Fig. 12 is a view of the interior of the Estacada plant of the Portland, Ore., Railway Light and Power Company. Here a pair of spiral case Francis type turbines is connected to each of the generators.

The total mechanical power used in the United States is estimated at about 180,000,000 horse power. The larger proportion of this is used by railroad locomotives, and for a wide variety of miscellaneous purposes. The amount of power used directly in manufacturing was estimated in 1909 as 18,680,776 horse power. Of this only 1,882,573 horse power was produced

directly by water power, and about an equal amount of hydro-electric power was purchased for manufacturing use. Central electric light and power stations produced at the same date about 7,500,000 horse power.

The developed water power of the United State was estimated at 6,000,000 horse power in 1909. While the total water power of the streams of the United States exceeds 100,000,000 horse power, the larger proportion of this is not capable of profitable development at the present time.

Thus while it appears probable that there may be a material increase in the use of water power in the near future, and consequent reduction in the annual coal consumption, it must be expected that an enormous consumption of coal for power purposes will continue for many years. The total water-power resources of the world have been estimated at about 700,000,000 horse power. See HYDRAULICS.

ROBERT E. HORTON,  
Consulting Hydraulic Engineer.

**WATER PURIFICATION.** See WATER SUPPLY; WATERWORKS.

**WATER-RABBIT, or SWAMP-HARE.** See HARES.

**WATER-RAIL,** a species of rail (*Rallus aquaticus*) widely distributed over Europe, Asia and North Africa and generally common, but, on account of its retiring habits and shyness, not often seen. It is about 11 inches long, olive brown above streaked with black, the under parts gray and the sides streaked. It frequents marshes and bogs, dives and swims well, but is a poor flyer. It is a delicious table-bird. In North America its nearest representative is the king rail (*R. elegans*). The name is applied generally to other species of aquatic rails (q.v.) in distinction from the land-rails and crakes (q.v.).

**WATER RAT, or VOLE.** See VOLE.

**WATER RIGHTS.** See RIVERS; RIPARIAN RIGHTS.

**WATER-SCORPION,** a bug of the family *Nepidae*, whose species inhabit ponds and take their popular name from the scorpion-like form of the fore-legs, with which they seize their prey. The remaining two pairs are slender and locomotory, and the abdomen terminates in a long, slender breathing tube. Some of the species carry eggs in a layer on the under side of the abdomen. *Belostoma* includes the largest species with flattened bodies and four-jointed antennæ; *Nepa* is much flattened and oval and the antennæ are three-jointed and lamellate; while *Ranatra* includes species of linear form. The larvæ and nymphs of the water-scorpions resemble the imagoes in general aspect, but lack the

wings of the latter. In all stages they are sluggish in movements and secure their prey by hiding and stealth. These insects are very interesting in habits and structure. See FRESH-WATER INSECTS.

**WATER SHELL.** See ORDNANCE.

**WATER-SNAKE**, a harmless colubrine American snake (*Notrix fasciata*), closely allied to the garter-snakes (q.v.), but of aquatic habits, swimming and diving with great ease and skill and spending its life largely in streams, ponds and marshes. It lives largely upon fish, either alive or dead, frogs, tadpoles, newts and aquatic insects and other small creatures. It is mottled in variable dull tints and is lively and pugnacious. Its eggs are laid in holes in stream banks and similar places. The common grass-snake (q.v.) of Europe, the only British serpent except the viper, is a near relative. The wart-snake of East India (*Acrocordus javanicus*) and the sea-snake, a venomous fish-eating hydrophoid of the Indian Ocean, also bear the name of sea-snake.

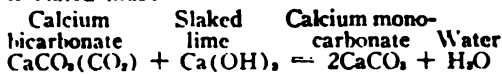

**WATER SOFTENING**, specifically the process of eliminating from water the calcium (lime) and magnesium compounds which combine with soap, forming insoluble curds and prevent the formation of lather, thus making the water "hard." In general the term embraces all forms of removal from water of any substance, lime, magnesia, acid, silt or other material which renders the water unsuitable for industrial use. The process has usually three phases: (1) the removal of scale-forming substances; (2) the neutralization or removal of corroding substances; (3) the separation of suspended matters. The first two are chemical; the third, mechanical. Rain water contains only the soluble gases of the air, carbonic acid gas, oxygen, ammonia and sulphurous acid and such dust and dirt as it may have washed out of the air in its fall. The water falling at the last end of a long rainstorm is nearly pure. Such water mixes readily with soap to form a slippery lather and the water is said to be soft. If rain water runs down a clean, grassy slope to a stream, it is still nearly pure soft water. If it runs over limestone or ground containing particles of limestone, it dissolves a small amount, perhaps two grains per gallon (of 58,391 grains) or one part of limestone to about 29,000 parts of water; but for practical purposes this is still called soft water. If, however, the rain water sinks into the ground to remain a long time in contact with limestone, it dissolves greater amounts, frequently 20 grains per gallon of water and sometimes more than 100 grains per gallon. Water is commonly said to be hard if it contains more than five grains per gallon. Deep well waters are nearly always of this nature. In the arid plains of the western part of the United States where the soil contains large quantities of common salt (chloride of sodium) and the other salts of sodium and potassium which are all readily soluble in water, the well waters are usually heavily charged not only with the salts of calcium and magnesium but also with the salts of sodium and potassium and such water is called alkali water. The water which is found near the coal fields frequently contains sulphuric acid to the amount of two or three grains per gallon.

Lakes contain the waters of many creeks and rivers and are usually soft water; but the current is slow or absent altogether and the evaporation from the broad surface has the effect of concentrating the volume of dissolved salts so that lake water contains rather more mineral matter than river water and is frequently on the border line between soft and hard. Lake Erie water, the softest of all the lakes, contains about five grains per gallon of the salts of calcium and magnesium. The oceans are the final receptacles for the waters of the rivers and lakes and are subject to continuous evaporation, so that in the course of years the mineral matter has become concentrated and ocean water contains about 2,100 grains per gallon of mineral matter, made up of calcium carbonate, eight grains; calcium sulphate, 75 grains; magnesium sulphate, 99 grains; magnesium chloride, 230 grains; potassium sulphate, 55 grains; and sodium chloride, 1,633 grains; the great amount of sodium chloride and the relative scarcity of calcium and magnesium compounds being due to reactions which have taken place in the water, precipitating the salts last mentioned. Great Salt Lake in Utah and the Dead Sea in Palestine (q.v.) are small bodies of water, like oceans, without known outlets, and since the rivers feeding them are heavily charged with common salt, these lakes contain much more of it in proportion than the oceans. Ocean water contains about 3.5 per cent mineral matter, the Dead Sea 26 per cent and Great Salt Lake averages about 20 per cent.

When hard waters are evaporated the mineral matter is left in a solid mass, interesting examples being found in the stalactites and stalagmites in caves and in the deposit in the bottoms of tea kettles. The most serious damage produced by hard water in industrial operations is the scale deposited in steam boilers and the waste of soap in washing. Scale in boilers is a deposit of the mineral content of the water evaporated, due in large part to the fact that some of the dissolved salts are more soluble in cold water than in hot and as the temperature rises the overplus is precipitated as a crust on the inside of the boiler plates. This condition prevents the easy passage of heat from the fire to the water and shortens the life of the boiler because of the excessive temperature to which the steel must be raised in order to force the heat through the scale to the water. The average heat conductivity of boiler scale is one-thirty-seventh of that of the iron of which the boiler is made when the scale is thin. If thick this figure is much too large. The amount of extra fuel required to evaporate water in a boiler which is coated with scale varies with the thickness and character of the scale and with the rate at which the boiler is worked. When the boiler is being driven to nearly its full capacity, the amount of additional fuel required by a one-quarter-inch layer of scale is frequently as much as 50 per cent; but if the boiler is being worked at only half its capacity the difference may not be more than 10 per cent. Nearly all tables of such data are based on measurements of the additional amount of fuel required in a scale-covered boiler to heat the water at the same rate as in a clean boiler worked at normal capacity. It is estimated that the railroads of the United States are spending at least \$15,000,000 annually in additional fuel

and boiler repairs due to the hard and muddy water used in some parts of the country. Using hard water in boilers is much more expensive than softening it, since on the average 1,000 gallons of hard water will do 50 cents worth of damage in fuel and repairs, while 1,000 gallons of hard water may almost always be softened for less than 3 cents. The value of the soap wasted by hard water is enormous, amounting to 1.7 pounds per 1,000 gallons of water for each grain of hardness, or 17 pounds per 1,000 gallons of water 10 grains hard per gallon, a value of at least 70 cents, when it would cost perhaps two cents per 1,000 gallons on the average to sufficiently soften such water.

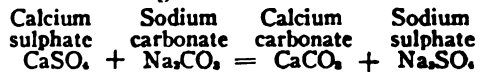

The chlorides and sulphates of calcium and magnesium are readily soluble in water, but the carbonate of lime or magnesium (marble or ordinary limestone) is soluble only in water which contains carbonic acid gas ( $\text{CO}_2$ ). The greatest difficulty with the magnesium salts is that they prevent or delay the removal of the calcium salts and by their presence raise the point of solubility for calcium carbonate. An increased addition of lime in this case results in the formation of magnesium hydroxide which forms very slowly and is very likely to assume a colloidal form, absorb carbonic oxide from the air and return to its first form. Calcium carbonate will remain in solution in ordinary samples of water to the extent of 2.04 grains per gallon. This amount, however, is not large enough to rate the water as "hard." If all the carbon dioxide is removed from the water the limit of solubility will be only 1.08 grains per gallon. And this remnant cannot be dislodged by the addition of caustic lime. Magnesium carbonate is much more soluble where carbon dioxide is present and while it rarely exceeds five or six grains per gallon, it is sometimes in much larger quantity. Even though all the carbon dioxide be removed the content of magnesium carbonate may remain at 12 grains per gallon. The higher the pressure in a boiler the more of this salt will be held in solution. Magnesium chloride, although highly soluble, is very objectionable in boiler water because of its tendency to decompose and produce hydrochloric acid, which is extremely corrosive. Calcium chloride is more stable, but under high pressure is believed also to break down into hydrochloric acid. It is a simple matter to soften water which contains only the bicarbonate of calcium, because it is necessary only to steal away the extra molecule of  $\text{CO}_2$  by adding a little fresh-slaked lime which has a great affinity for carbonic acid gas and combines with it to form a molecule of mono-carbonate of calcium, which is insoluble, and, like the remaining molecule of mono-carbonate, settles to the bottom as precipitate. The chemical reaction is stated thus:

and thus there is precipitated to the bottom not only the original dissolved limestone but also the slaked lime which has become limestone by uniting with the molecule of carbonic acid gas which held the original limestone in solution. This discovery or invention was made in England by Dr. Clark about 1840 and no better or

cheaper method has since been found for removing carbonate of lime from water. Calcium carbonate alone does not form a hard scale in boilers but produces a soft, slimy silt. In combination with other salts, however, it makes the hardest of scale.

In the case of the sulphate of calcium heavy crystals are deposited whenever the boiler pressure reaches or exceeds 50 pounds. The sulphate of calcium scale is regarded as worst of all. The solubility of calcium sulphate is increased by the presence of magnesium chloride and decreased by the presence of calcium chloride. At high boiler pressure very much less of calcium sulphate is held in solution, the excess being precipitated. At ordinary temperatures water will hold in solution 150 grains per gallon. At a temperature of  $356^\circ \text{F}$ ., equivalent to a pressure of 132 pounds per square inch, the solubility per gallon is but 16 grains, the remaining 134 grains per gallon having been deposited as scale. The ordinary method of taking out sulphate or chloride of calcium is to add to the water the proper amount of sodium carbonate (soda ash or washing soda), when the sodium and calcium exchange acids as follows:

The calcium carbonate settles as a precipitate while the sodium sulphate remains dissolved in the water, and, for boiler or washing purposes, is harmless in any ordinary amount. In water softening operations the treatment for the magnesium salts is practically identical with that for calcium salts. Mud in suspension is taken out of soft water by introducing a coagulant, as alum, or the combination of two substances which will form a precipitate — such as sulphate of iron and caustic soda, so that the precipitate in settling will carry down with it the fine particles of mud. The oil taken up by steam in engine cylinders is extracted from the condensed water in the same way, so that the water may be used again in the boilers. For boiler purposes it is most important that the softened water should be freed from precipitate and made perfectly clear, because the presence of particles of solid matter suspended in the water is the most potent cause of boiler foaming. When the reactions take place and the young and fine precipitates are formed, in the presence of old precipitate, an agglomerating action results which gathers the small particles together in balls so that they settle readily. The best machines in use for carrying out these processes are automatic in their action and require only to be supplied with chemicals and to have the settled precipitates discharged by opening a valve at the bottom of the settling tank, each once in 24 hours.

The most recent and apparently the most successful of all water softening processes is the use of zeolites, natural or artificial. These substances are silicates containing water, and which, in contradistinction to other silicates, decompose and are soluble in dilute acids. The artificial form is produced by fusing together feldspar, kaolin, pearlsh and soda in certain fixed proportions; and goes by the commercial name of "permutit." Two forms are in use — sodium permutit and manganese permutit.

When water is made to flow through a layer of sodium permittit, the latter exchanges its soda for the calcium and magnesium salts of the water and the degree of hardness in the latter is reduced to zero. The permittit has to be regenerated as it grows lax in action. This is easily accomplished by washing it for a few hours with a solution of common salt. Manganese permittit in connection with marble dust removes all iron and acids from waters thus affected.

The practice of softening the entire water supply of a municipality has grown steadily and in not a few large manufacturing cities the municipal softening plant is saving the citizens hundreds of thousands of tons of coal per annum and adding years of life to the community's boilers. The principal requirements are (1) mixing chambers, in which the softening chemicals are thoroughly mixed with the water; (2) capacious settling basins sufficient to give the necessary time for the slower reactions when the temperature is low, as in winter; (3) a device for adding a coagulant (alum or ferrous sulphate) at both the entrance port and the exit port of the water into and from the settling basins; (4) substantial mechanical filters. In addition, as one of the requisites should be a special apparatus to slake the lime, reduce it to a proper emulsion and feed it in proper quantity automatically into the flowing water.

At the municipal water softening plant at Cleveland, Ohio, 150,000,000 gallons of water per day require the daily application of 40 tons of quicklime. This is slaked with hot water, mixed into an emulsion in an agitator, taken to tanks where it is cooled and diluted to the proper consistency and finally pumped at a uniform rate into the flowing water.

In a recent report (1916) upon a water supply for the city of Sacramento, Cal., the relative hardness of the available waters was considered in estimating the cost of the project. The engineers showed that while a supply of water from ground wells would be cheapest in initial outlay, that the water of the Sacramento River would be more economical for the consumers because of its lower degree of hardness; the ultimate figures being \$38.40 per 1,000,000 gallons for the river water as against \$42.40 per 1,000,000 gallons for well water. On the basis of the city's daily consumption of 30,000,000 gallons the saving in soap alone to the consumers amounted to \$120 per day. Consult Booth, W. H., 'Water Softening and Treatment' (London 1906); Christie, W. W., 'Water: Its Purification and Use in the Industries' (New York 1912); Whipple, G. C., 'The Value of Pure Water' (New York 1907).

C. HERSCHEL KOYL,  
Consulting Engineer, New York.

**WATER SUPPLY:** For Municipal, Domestic and Potable Purposes, Including Its Sources, Conservation, Purification and Distribution. Introduction.—This article does not treat of water supply for navigation, irrigation or power development, but is confined principally to the consideration of the sources, collection, conservation, purification and distribution of water for municipal, domestic and potable purposes. This is becoming an increasingly engrossing subject for all progressive communi-

ties, since scientific research has shown that many natural waters are the media for the propagation and dissemination of countless colonies of micro-organisms of vegetative and animal growths, including bacteria, some of which are pathogenic. Some water bacteria have been localized and classified as shown by Prescott and Winslow in their 'Elements of Water Bacteriology.' Many other micro-organisms have also been localized and classified as shown by George C. Whipple in his 'Microscopy of Drinking Water.' The nature and characteristics of some of these organisms must be studied in all water supply problems and therefore will be considered to some extent under some of the subtitles to follow.

In 1857 Nägel suggested the name "schizomycetes" for all micro-organisms and that designation is used by some bacteriologists for all such organisms. Botanists use that designation for vegetative organisms. "Bacteria," however, is the name usually applied to living organisms in water. Many of these infest surface and ground waters. Neither lakes, rivers, ponds, nor wells are free from such micro-organisms. Not infrequently thousands of bacteria are found in a cubic centimeter of natural, which is usually denominated "raw" water. Dr. A. H. Hassall of London (1850) is reported to be the first to identify living organisms in drinking water. He was followed by E. N. Horsford, L. Radlkofer, Ferdinand J. Cohn, James Bell, L. Hirt, W. G. Farlow, Ira Remsen, H. C. Sorby, J. D. Hyatt, George W. Rafter, George C. Whipple and others. Dr. A. C. Houston of the London Metropolitan Board in 1912 reported 10,315 microbes per centimeter of raw Thames water, although says Prof. William P. Mason "it is now generally admitted that such a medium is not favorable to their growth." Dr. Houston found that they lived longer in deep Loch Katrine water, one of the sources of supply for Glasgow, than they did in the Thames.

Dr. Robert Koch traced the cholera epidemic of 1892, in Hamburg, which did not prevail in Altona across the Elbe, to the contamination of its unfiltered raw river water supply by the cholera germ, *spirillum cholerae Asiatica*, or *comma bacillus*, discovered by Koch in 1884. Altona used filtered water from the Elbe and largely escaped that cholera epidemic. Since the discovery of the specific cholera germ by Dr. Koch, greater caution is exercised by municipalities to prevent the contamination of their water supplies by the *spirilla cholerae Asiatica*, and cholera epidemics are less frequent. In 1887 Messina, Sicily, had an epidemic of cholera due to polluted water. Typhoid epidemics have occurred more frequently than Asiatic cholera, for the typhoid bacilli (*B. typhosi*) are more generally distributed and the contamination of water supplies thereby has been not uncommon. George C. Whipple in 'The Microscopy of Drinking Water,' p. 80, says, "All quiescent surface-waters are liable to contain microscopic organisms in considerable numbers. The water that is entirely free from them is very rare."

From the 'Waterworks Handbook' of Flinn-Weston and Bogert and other publications are excerpted the following data as to bacterial contents of a few river waters per cubic centimeter.

Bacteria in the Niagara vary from 10,000 to 300,000 per cubic centimeter; in the Seine from 300 per cubic centimeter above Paris to 200,000 per cubic centimeter below Paris; in the Spree from 82,000 per cubic centimeter above Koenig to 10,000,000 per cubic centimeter at Charlottenburg; in the Ohio they averaged 16,500 per cubic centimeter; in the Delaware 7,680 per cubic centimeter; in Crystal Lake, Mass., 185 per cubic centimeter; in Lake Ontario 7,040 per cubic centimeter; in the Mississippi upwards of 2,000 per cubic centimeter; in the Potomac upwards of 4,000 per cubic centimeter and in the Merrimac upwards of 11,000 per cubic centimeter; in raw Thames water 10,315 microbes per cubic centimeter; and in the Isar at Munich opposite an effluent of sewage 121,861 per cubic centimeter. In some waters bacteria have exceeded 200,000 per cubic centimeter. Nearly all surface waters have some bacterial content and in many cases the bacteria are pathogenic. Neither are all springs nor well waters entirely free from bacterial infestation. This may not be sufficient nor of the kind to pollute such waters for some genera are not pathogenic. However, it has been contended that some non-pathogenic bacteria may become pathogenic under favorable conditions. That is notably so in the case of *Bacillus coli communis* (*B. coli*), when nourished on sewage and on other typhoid waste.

Ground waters, including wells, in some localities are infested with *Crenothrix* at the number of 20,000 per cubic centimeter and with similar organisms, where iron and manganese are found. The *Crenothrix* flourishes in waters impregnated with iron and *Crenothrix* itself secretes iron and clogs water pipes. Many other species have been found in ground waters, though they may not all be pathogenic. Some time ago the Massachusetts Board of Health tabulated those found in ground waters. In recent years, possibly from China, there have been imported with livestock, or by means of their hides, the dread anthrax spores (*B. anthracis*) discovered by Robert Koch in 1876, which have been discharged from tanneries into rivers. They are immune to the ordinary agencies used for the sterilization or purification of water supplies. Turneure and Russell reported in their 'Public Water Supplies' that in Medford, Wis., a well was contaminated by surface water draining into it from a field, where cattle had died of anthrax or splenic fever.

The *Bacilli tetani* (*B. tetani*) and many other species have been discovered in raw river water. In 1900, George C. Whipple compiled data showing the relative abundance of *Diatomaceæ*, *Chlorophyceæ*, *Cyanophyceæ* and *Protozoa* in 57 lakes, ponds and storage reservoirs of Massachusetts. Consult Whipple's 'Microscopy of Drinking Water' pp. 139-141. None of such waters were entirely free from some one or more genera of such organisms. They may be considered as fairly representative of all surface waters.

As a result of the prevalence of pathogenic bacteria in water supplies, waterborne diseases are many and include those already mentioned and many other intestinal, tubercular and other disturbances. It is the aim of modern research to prevent all such diseases and to that end

new processes for the purification of water supplies have been perfected. New standards of purity and wholesomeness have been established to which water supplies must conform before they are considered safe for potable uses. Some of these will be considered in this article, which will comprise several subtitles.

**Primitive Conditions.**—In the primitive conditions of society the water supply of a territory received but little attention. The early inhabitants of the world were more interested in its availability and abundance than they were in its quality. Accordingly the most populous settlements were those along oceans, seas, gulfs, bays, lakes, rivers and watercourses generally. Early palæolithic remains have been found along the Thames. In the Stone and Bronze ages dwellings for human habitation were built on poles in the lakes of Switzerland, the British Islands and elsewhere and mounds were constructed along the coasts in Scandinavia. Their occupants were thus abundantly supplied with water as well as protected from the ferocity of wild animals. Primitive peoples, however, knew little or nothing about the animal and vegetative organisms, in surface, running or stored-up water. At first there was little, if any pollution of watercourses by human agencies. The early inhabitants supplied their needs from nature's inexhaustible reservoirs without fear or even the knowledge that water in any of its manifold forms might be unsafe for domestic or for general potable uses. That is a matter of recent deduction from the slow discovery of species of pathogenic bacteria, in surface and other polluted waters. Some of these develop and propagate readily when taken into the human system as do *Bacilli coli communis*.

Prior to the 19th century of our era there are few extant records of the ravages of diseases and the destruction of human life, attributed to the potable uses of unwholesome water. Many wasting fevers, pestilences and plagues are recorded in history prior to the discovery of the deadly species of microscopic organisms in contaminated water, but their causes were unknown. As the population increased and extended from watercourses inland, tanks, storage reservoirs and canals were constructed as they were in Assyria, Babylonia, Egypt and China. The sources of the Tigris and Euphrates and the waters of those rivers themselves were conveyed through a network of canals to water the many cities of Mesopotamia whose water jars have been found at Nippur and elsewhere. Khammurabi provided for the protection of some of such canals in his Code of Laws, promulgated 2250 B.C. Egypt was watered by the Nile, whose constant flow was maintained by drawing upon the impounded waters of Lake Moeris. Asia Minor had many springs, notably those in the valley of the Mæander. The Arabians utilized extinct volcanic craters as reservoirs for the accumulation of waters. Greece had its rivers, springs and infiltration galleries. Rome had its lakes, springs, aqueducts, reservoirs and rivers. Carthage and Palestine had their wells, cisterns and pools, supplied by mountain streams. India had its rivers, canals and reservoirs. All those ancient peoples and also the Chinese had their deeply driven wells, which supplied their best waters. Herod-

otus, Hippocrates, Strabo, Pliny and others wrote on the water supply of various countries.

Æschylus in his 'Eumenides' speaking through Athena said:

Κακὰς ἐπιρροαίαι· βορβόρω θύδαρ  
λαμπρὸν μαιῶν ὄπισθ' εὐρήσεις ποτῶν.

which has been translated as follows:

"But if with streams defiled and tainted soil  
Clear river thou pollute, no drink thou'lt find,"

thus warning the Athenians of the dangers in polluted water.

Hippocrates recommended that drinking water be filtered and boiled before using it. That is some proof that he realized that raw water ought to be sterilized before it was drunk. The Romans knew that some waters were unsuitable for drinking purposes and used their poorer qualities for irrigation, municipal fountains and other public non-potable purposes. Not until the advancement of science in the 19th century had revealed waterborne diseases, did the quality of the water supplies of communities arouse public attention.

**The Germ Theory of Disease.**—The modern sciences of bacteriology and biology revealed the nature and activities of myriads of microscopic organisms in impure water hereinbefore partially described and how they become the media of infection and the agencies for spreading diseases. After the discoveries of Theodor Schwann, Louis Pasteur, Robert Koch, Ferdinand J. Cohn, Joseph Lister and others during the last century "the germ theory of disease" was generally accepted. Those pathologists turned their attention to the discovery of means of combating the active agencies that were destructive of human life. They made several important discoveries of antitoxins, serums and lymphs of inestimable pathological utility to the race. These, however, were insufficient to check the ravages of all infectious diseases, some of which, as was stated, are transmitted through living organisms in potable waters. That led to the study of the water supplies of communities, one of the most engrossing subjects of the last and present century. Municipalities and communities generally for their own welfare must consider and solve this problem regardless of the expense thereby entailed upon taxpayers, for it is growing in importance in many habitable parts of the globe with the ever-increasing density of population. Before entering upon the study of the processes for the purification of water supplies, it may be well to consider some of the physical conditions that contribute to the production of the abundant waters, found in the habitable portions of the earth.

**Earth's Water Supply.**—Three-fourths of its surface is covered with salt water and from those inexhaustible fountains of the deep the heat of the sun is continually drawing invisible vapor up into the strata of the atmosphere, where the aqueous vapor is cooled and becomes visible and is wafted landward over continents. It comes in contact with hills and mountain ranges and is precipitated in rain and snow and so replenishes the infinite water sources of the uplands of the earth. Whether in some one of its varied forms, it accumulate in insurmountable masses of snow, giving mountain

ranges their names as it did the Himalayas, or in another form it become rivers of ice, like Alpine glaciers to form such commerce-bearing rivers as the Rhone, or in another form it roll in ceaseless tidal billows encircling the globe, or still in another form it float in vaporous clouds landward to fall in refreshing rains over vast areas of territory to percolate the soil and be stored in an infinite number of natural reservoirs, whence it flows in countless streams to nourish the fruits of the earth and supply the wants of man, it conditions and largely controls the activities of every generation and will continue so to do for all time.

Next to the free air we breathe, water is man's greatest earthly possession. Water is freely showered upon the earth in abundance and is stored up in countless pools, ponds, ground waters, subterranean springs and other natural reservoirs and is accumulated in brooks, creeks, streams, rivers, lakes, sounds, bays, seas and the oceans, covering three-fourths of the earth's surface and making habitable a large part of the remaining fourth. Its distribution is affected by the uplift and physical configuration of continents and their relation to oceans, the rotation of the earth upon its axis, the temperature, humidity, succession and varying seasons, climate and trade and other prevailing winds. All of these and other natural phenomena more or less condition the amount of precipitation over different areas. Some lofty mountain ranges, continually intercepting vaporous clouds swept inland from the oceans and seas, are capped with permanent masses of snow, which are unfailing sources of water supply for great rivers like the Amazon, the Yukon, the Rhone, the Ganges and others. Other mountain ranges cause almost daily precipitation in the form of rain, which collects in innumerable natural basins on the surface and below it, but high above the sea-level. These are the source of mountain streams and of the occasional underground flow found in some mountain regions. The amount of precipitation varies over different areas. In the polar regions there is no rain and all precipitation there is congealed in the form of snow and icy particles. Rainfall or precipitation is quite fully treated in the special article under the title, RAINFALL, in Volume 23 of this Encyclopedia, to which reference is herein made for the amount thereof over various areas of the habitable globe.

Under the operation of natural laws only a part of rainfall can be collected, conserved and made available for human needs. As announced under the article on RAINFALL communities must also consider its disposal. That will appear from what follows.

**Disposal of Precipitation.**—Water from rain or melting snows disappears from the catchment areas, (1) by evaporation, (2) by transpiration, (3) by runoff and (4) by percolation. These methods dispose of varying amounts dependent somewhat upon the surfaces, whether land, or water, the seasons, climate, temperature, locality, altitude, vegetation, character of the soil and other physical conditions. They may be briefly stated as follows:

(1) Evaporation to some extent already considered under the article on RAINFALL may

dispose of any part or all of the rainfall over a limited area and in some instances evaporation may exceed rainfall, as it did in Massachusetts in 1883. Evaporation goes on from ice and snow less rapidly than from land or water surfaces. Vegetation and trees intercept precipitation and also retard evaporation. They tend to increase percolation for the moisture penetrates the soil in and about the roots and is held there until it percolates into the deep strata of the earth. Various formulæ have been deduced to determine evaporation, as stated in the article on RAINFALL. These, however, are not conclusive.

Capillary attraction acts upon water 30 or more inches below the surface and occasionally lifts a film of water 6 to 30 inches above the ground-water level and so aids evaporation. Wilton Whitney, in 1897, reported ('Agriculture Year Book') that capillarity drew moisture up 20 feet or more to nourish crops in the soils of California. Prof. J. B. Stewart of the Agricultural College of Michigan reported that capillarity operated upon water from 45 to 70 inches below the surface. The depth of the water-table below the surface is not uniform and varies in different localities. In the Central States it was found by W. J. McGee to be about 22 inches below the surface. Charles H. Lee of the Geological Survey was of the opinion that the capillarity lift is limited to four feet in coarse sandy soil and to eight feet in fine sandy and clay soils. Thus by the operation of natural laws is the verdure of the earth nourished and sustained from the waters below, though there be insufficient precipitation from above. Warm sunshine and gentle winds increase evaporation.

From some soils evaporation averages 16.68 inches annually, where the rainfall is 30.29 inches and the percolation 13.61 inches. Over the Ohio River watersheds, where the rainfall averages 41.1 inches, the evaporation averaged 14.8 inches; over the James River watersheds, where the rainfall averaged 42.1 inches, the evaporation averaged 16.3 inches; and over the Sacramento River watershed, where the rainfall averaged 32.2 inches, the evaporation averaged 8.5 inches. Evaporation from the Croton watershed was computed by John R. Freeman for a period of 32 years at 24.74 inches. Evaporation has been computed over the Sudbury watershed at 23.63 inches and at Nashua at 23.76 inches. From water surfaces evaporation is much greater than from land surfaces. From the Chestnut Hill reservoir near Boston for a period of years it averaged 39.2 inches and from a water surface at Croton, N. Y., it averaged 39.68 inches. From Mount Hope reservoir at Rochester for 10 years, it averaged 44.45 inches, from the Muskingum River 40 inches, from Owens Lake, California, 80 inches, from Yakima River, Washington, 32.8 inches, from East Lake, Birmingham, Ala., it ranged from 52.1 inches to 69.4 inches.

The United States Weather Bureau and United States Department of Agriculture for some years have compiled a record of evaporation from the principal watersheds of the United States. These show that about two-thirds of rainfall or precipitation over the United States is disposed of by evaporation

In Massachusetts in 1883, evaporation was 39.12 inches and rainfall was only 32.78 inches.

From a water surface at Lea Bridge, England, it averaged 20.6 inches, whereas for 14 years it averaged 18.14 inches from land surfaces, where the rainfall was 25.72 inches. At Rothamsted, England, evaporation averaged 16.68 inches, where rainfall averaged 30.29 inches. From Talla reservoir, Edinburgh, it averaged 15 inches. The characteristics of land areas and their general physical conditions, together with atmospheric influences, affect evaporation.

(2) Transpiration also disposes of an appreciable amount of rainfall in some localities through grasses, grains, other vegetation, shrubbery and trees and by them returned to the atmosphere. *Bulletin No. 285* of the Bureau of Plant Industry of the United States Department of Agriculture shows the water requirements of various cereals and plants. Prof. Adolph T. Meyer states that "For grasses and grains the ratio of pounds of water used to pounds of dry substance produced varies from 300.1 to 600.1." B. E. Livingston has undertaken to show (*40 Botanical Gazette* 31) that there is a direct relationship between transpiration and the weight of vegetables produced. The Department of Agriculture of the United States has also undertaken to show that the yield of grain of an area is approximately proportionate to the water consumed. It will thus be seen that large quantities of water are taken up by the growing vegetation and forests of the earth and returned to the atmosphere. Growing crops absorb from 9 to 10 inches of rainfall and brush and trees from 4 to 12 inches of rainfall according to estimates made by Professor Meyer. Nearly all such water escapes from the stomata of leaves into the air, for the amount retained is very slight. Raphael Zon of the United States Forestry Bureau reported in 1913, that one acre of oak forest in Austria absorbed upwards of 2,227 gallons of water daily, which was equivalent to a rainfall of 12½ inches in a period of five months. These figures indicate the enormous quantities of water given off by forests into the air.

The United States Department of Agriculture collected data in Central Europe showing the transpiration from forests to equal one-fourth the rainfall there. From deductions of M. W. Harrington it appears that much of the rainfall is transpired into the atmosphere by green crops and three-fourths of it from some forests and less than one-third from bare soil. During the growing season plants and trees draw moisture and water from the subsoils and thence it escapes into the atmosphere. The amount of water so taken from the ground by the capillary attraction in vegetation, plants and trees and by them transpired into the atmosphere varies greatly under different physical conditions, but enough has been stated to indicate that an appreciable part of the precipitation is thus disposed of and under some conditions that amounts to 20 inches.

(3) The runoff from different watersheds also varies greatly, depending upon their physical characteristics, including their geological structures and configuration. Sandy surfaces freely absorb water and from them there

is little runoff, whereas clay and rocky soils absorb but little rainfall and from such surfaces the runoff is large. Steep slopes also shed water freely, whereas forest-clad areas retard, absorb and retain a large part of the rainfall. The following data will illustrate the amount of water disposed of in the localities mentioned by runoff. The runoff waters from catchment areas or watersheds accumulate in pools, ponds, lakes and rivers and become one of the two available sources of water supply, the other being ground-waters. From the Genesee River at Mount Morris, N. Y., from 1892 to 1898, the runoff ranged from 6.67 to 19.38 inches, averaging about 12 inches.

Prof. Adolph F. Meyer in his work on 'Elements of Hydrology' says that evaporation and transpiration dispose of 15 to 25 inches of rainfall and the remainder represents runoff which includes seepage and percolation. The latter will be considered under the next sub-title. From the map of the Geological Survey prepared by Henry Gannett, it appears that the surface runoff over different watersheds ranges from three inches in the States east of the Rocky Mountains to 60 or 80 inches in the northern Pacific States. In the Central and Eastern States, it approximates 20 inches. Each watershed, however, must be independently studied to determine its runoff. This varies greatly in the different months and necessarily averages much less than the rainfall. Where the mean precipitation over the upper Mississippi reservoirs was 24.62 inches, the mean runoff was only 3.61 inches and the percolation averaged 14.7 inches. Over the Mississippi watershed it averaged 5.31 inches, or nearly 25 per cent of the rainfall. The rate of runoff to rainfall ranged from 15 per cent in the Missouri Basin to 24 per cent in the Ohio Basin. In Ohio it amounted to 22 inches. At Saint Croix, Wis., it was 9.6 inches, at Roanoke, Va., it was 17.7 inches. In the Yazoo and Saint Francis basins, the runoff was 90 per cent of the rainfall. Over the Connecticut River where the precipitation for nine years averaged 36 inches, the runoff averaged 21.9 inches. From the James River watershed for seven years, it averaged 18 inches. At Tohickon Creek for 24 years, it averaged 26.10 inches. At Tombigbee, Miss., it averaged 17.10 inches, at Sacramento, Cal., it averaged 20.4 inches. Over the Sudbury River, where the precipitation for 25 years averaged 45.4 inches, the runoff was 21.5 inches. In the State of New York it averaged about 45 per cent of the rainfall.

John C. Hoyt and Robert Anderson in their 'Hydrography of the Susquehanna River Drainage Basin,' reported that the runoff in that part of the basin above Harrisburg from 1891 to 1904, averaged from 49 to 55 per cent of the rainfall and at other places in the basin from 49 to 63 per cent of the rainfall. Over the Nashua River where the precipitation for 13 years averaged 47.3 inches, the runoff averaged 23.9 inches. The runoff averages nearly 50 per cent of the rainfall in New England. Over the Croton River, where the precipitation for 43 years averaged 48.9 inches, the runoff averaged 23.3 inches. Over the Milburn-Massapequa watershed, Long Island, N. Y., where the mean precipitation was 46.41

inches the runoff was about 30 per cent thereof. Over the Susquehanna River, where the precipitation for 10 years averaged 38.4 inches, the runoff averaged 21.3 inches. Over the James River in Virginia, where the precipitation for 14 years averaged 42.3 inches, the runoff averaged 17.9 inches. Over the Potomac River, where the precipitation for 14 years averaged 37.4 inches, the runoff averaged 14.4 inches. Over the Muskingum, where for seven years precipitation averaged 41.21 inches, the runoff averaged 14.20 inches. Over the Rock River, Illinois, where the precipitation for five years averaged 33.88 inches, the runoff averaged 10.03 inches. George W. Rafter in 'Water Supply and Irrigation Papers No. 80 United States Geological Survey' gives the runoff for various years over 12 watersheds, and it averaged from one-third to one-half the rainfall.

Over Saale River, in Germany, where for 14 years precipitation averaged 23.78 inches, the runoff averaged 7.17 inches. Over Remsched Dam in Germany, where for nine years precipitation averaged 45.62 inches, the runoff averaged 30.78 inches. Over the Woodburn River in Ireland, where precipitation was 36.29 inches, the runoff was 23.04 inches. Over the Buffalo River in South Africa, where precipitation was 29.52 inches, the runoff was 5.30 inches.

The mean runoff from 20 watersheds in France is nearly 50 per cent of the precipitation, while in Germany the mean runoff from nine watersheds does not, excepting in three instances, exceed one-third the precipitation.

The mean runoff from the watersheds of Great Britain ranges from 50 per cent to 75 per cent of the precipitation. The foregoing data, largely from approved reports, indicate observed runoffs. They are not merely estimates from curves which are fraught with more or less error, owing to the failure in some instances to take into consideration all the necessary physical elements of a given watershed to determine its actual runoff.

The French physicist, G. Lidy, proposed the equation of  $P + E + R = R''$ , wherein P stands for percolation, E for evaporation, R for runoff and  $R''$  for rainfall, but that does not always accord with actual measurements. Atmospheric and material conditions may so affect the factors of the equation as to make an unbalanced equation.

T. U. Taylor, of the Society of Civil Engineers, well says: "Runoff is a complex factor depending on rainfall topography, vegetation, kinds and condition of the soil at the time of the rains." (Proceedings of the Society of Civil Engineers, Vol. XL, p. 166).

(4) Percolation is the descent of water from rain or snow, or from other sources into the porous strata of the earth due to gravity. Water thus descends to the saturated horizon usually a little above the water-bearing level of the ground water. As the latter is drawn upon by capillarity and ceaselessly flows away between the strata of the earth, it is depleted and the percolating waters replenish the losses. Such "gravity waters" descend, where the soils do not admit of capillarity. Ground waters fill the subterranean channels, supply springs and wells and descend

"Through caverns measureless to man  
Down to a sunless sea."

The subterranean Rubicon in Belgium is a river of ground waters.

Ground waters are well nigh unfailing sources of water supplies as we shall see from what follows. As already stated, percolation disposes of what is left after evaporation, transpiration and runoff have eliminated a large part of the rainfall. It is conditioned somewhat upon the physical formation of the territory and also upon climate, temperature, elevation and slope of watershed. On mountain slopes and hillsides, where the surface and strata are tilted, there is little percolation, but excessive runoff. Permeability of the strata determines their storage capacity. Soils, unconsolidated deposits, sands, gravels, sandstones, porous limestones, slate, till, conglomerate quartzite and other rocks absorb quantities of water dependent upon their porosity. The denser rocks, such as granites, gneisses and schists are relatively impervious to saturation and in such geological formations only in joints, faults, bedding planes, caverns and subsurface basins and channels is water collected. The porosity of all these different strata and the physical conditions of the earth's crust largely control the amount and depth of percolation, which ranges in different locations from 10 per cent to 50 per cent of the precipitation.

Into some soils over which the rainfall is 30.29 inches the percolation averages 13.61 inches thereof. On Long Island it was estimated by the Burr-Hering-Freeman Commission to be from 30 per cent to 50 per cent of the rainfall and to range from 15 to 25 inches, conditioned upon the dry and wet years. In Muhlthal, Germany, where the rainfall was 47.1 inches, the percolation was found by Walter E. Spear to equal 30.42 inches. He estimated the percolation in Germany to equal 50 per cent of the rainfall, in Holland to range from 11.1 inches to 15.3 inches of the rainfall and in Belgium to range from 6 to 9.7 inches of the rainfall. Herbert E. Gregory estimated that 25 per cent of the 46.89 inches of rainfall over Connecticut is absorbed in the ground, while in some sections of the United States such absorption is greatest during the period of heaviest rainfall and then it ranges from 80 per cent to 95 per cent of the precipitation. In this manner water enters the strata of the earth and forms underground streams or is collected in springs and in subsurface basins. Such waters are known as ground waters and supply wells and also flow toward river beds and to adjacent waters, such as lakes, seas and oceans. Ground waters are also supplied from streams flowing over the surface. Large habitable areas are supplied from underground flow by means of innumerable wells, tapping that flow, or by means of springs or by means of conduits, as on Long Island, or by means of infiltration galleries, as in some parts of Belgium, Holland and Germany.

I. M. de Varona found that the amount of ground water recovered from Ridgewood drainage area of 65.4 square miles in 1890, when the rainfall was 52.15 inches, was 17.68 inches, which was 33.9 per cent of the former. For several years in that area such amount ranged from 28 per cent to 33 per cent of the precipitation. The Board of Water Supply estimated that, if the Ridgewood watershed were

completely developed, the yield of ground waters in normal rainfall years would be near 1,000,000 gallons a day for each square mile of area. They reported that the old watershed was yielding 900,000 gallons a day per square mile and the new one was yielding 700,000 gallons a day per square mile. The Burr-Hering-Freeman Commission from its investigation concluded that, in addition to the water being pumped in 1903 for Brooklyn, there might be obtained 200,000,000 gallons per day from the southern watersheds of Long Island.

The underground reservoirs of California are structural basins filled with the alluvial debris, due to the weathering of the adjacent mountain ranges. Through such alluvial deposits precipitation percolates to the impervious rock below. The ground waters are thus collected and their only escape is through some possible subterranean or known surface channels. Evaporation or springing or seeping through the overlying deposits at the lower side of the tilted, but elevated, basin. Such ground water may be used and in some mountain localities are being drawn and conducted to irrigate desert areas and to supply needy communities with wholesome waters.

The report of the State Water Conference of California in 1916 shows that many of California's water problems were considered and recommendations made for drawing upon the ground waters in the San Joaquin and Sacramento valleys and elsewhere to irrigate the arid lands where there is insufficient precipitation to make such lands productive and also to supply waters for municipal purposes.

The extent and quality of some ground waters are shown in the Water Supply Paper of the United States Geological Survey as follows: for Connecticut in Paper 232, for Kansas in Paper 273, for Iowa in Paper 293 and for Owen Valley, California, in Paper 294.

Some of the legal principles applicable to ground waters in Europe and America are stated in *Bradford Corporation v. Ferrand*, Ch. 655; also fully reported in two British Ruling Cases, 980; *The People v. New York Carbonic Acid Gas Co.*, 196 N. Y. 421; *Lindsay v. National Carbonic Acid Gas Co.*, 220 U. S. 61; and in the annotations to the first of such cases and in the other cases referred to in such cases. Consult 'Water Supply and Irrigation Paper No. 122,' United States Geological Survey.

The Board of Water Supply of New York reported in 1912 that the Brussels watershed of 4.6 square miles yielded 2,100,000 gallons a day, that The Hague sand dune catchment area of 7 square miles yielded 5,100,000 gallons a day, that the Amsterdam sand dune catchment area of 11.6 square miles yielded 6,100,000 gallons a day, and that the Muhlthal watershed of 14 square miles yielded 21,300,000 gallons a day.

These few records indicate the large quantities of ground waters obtainable from the watersheds mentioned for water supply purposes. They also indicate the quantities of percolation into the strata of the areas described. They also indicate the amount of water stored in the earth's strata for water supply purposes. Some of the ground waters, however, find their way to the surface by seepage through sands and gravels, emerging in ponds, streams and springs. Such seepage is the outflow through

the surficial layers of ground waters flowing downward from the water-tables above. Whenever the ground water level is higher than the surface or depressions in the surface, the water "seeps" through the sands and gravels and appears as already stated. This is noticeable in marshy areas in the period of heavy rainfall and also in the many mineral and other seepage springs found in mountainous districts as well as in such streams as those on Long Island. The amount of ground water thus returned to the surface is but a small percentage of the volume of underflow, the amount and rate of which in some localities have been determined and reported by Charles S. Slichter of the Geological Survey. The winter flow of Minnesota streams is largely seepage waters.

Ground waters are being continuously replenished by percolating waters coming from precipitation, the amount of which the world over must be known to ascertain the volume of surface and ground waters available for the water supplies of the inhabitants of the earth. They are also replenished to some extent from surface waters in some regions.

Percolating waters descend to the surface of the saturated strata and become part of the permanent ground waters of the region. The saturated strata known as "water-bearing formations" are several hundred feet in thickness and overlie the strata that are impervious to water. The surface of saturation is known as "the ground-water level" and may be within a few feet of the surface. Above this saturation is not constant. Hence, to insure a continuous supply, wells must be deep enough to reach the ground water level, and as that fluctuates in different regions and in the wet and dry seasons, it is necessary to drive wells some distance below the level. From the several water horizons, comprising strata, consisting of different geological formations, various qualities and quantities of water are obtainable. Geological and water supplies reports of this and other countries may be consulted for specific information in relation to the nature of the ground waters of any region covered in such reports. Myron H. Fuller and others of the United States Geological Survey have compiled much valuable data on the ground waters of the United States of America. From their reports as well as from others it appears that the water-bearing horizons are not always horizontal, but incline either up or down in most watersheds, and the force of gravity causes a flow of ground waters between the layers of such horizons, "mainly," says Herbert E. Gregory, "in the same direction as the slope of the surface." Such flow is very slow, being from a few feet to a mile or more a year, depending on several conditions, such as character of the water-bearing formations, temperature, slope, percolation and other physical elements. The flow, however, is continuous and replenishes wells, springs and streams, as they are drawn upon, or otherwise discharge their waters. Springs and flowing wells exist in Connecticut, Michigan, Iowa, California and elsewhere. These and thousands of other wells in all lands are fed from the inexhaustible ground waters of the earth to supply human needs. Copenhagen draws its entire supply from wells down through glacial drift to chalk deposits.

Some of these may be hereinafter mentioned,

as they are the principal sources of the water supply of most rural populations.

Water supplies are obtained from waters that run off from catchment areas and from waters that percolate the strata of the earth. Before considering any particular water supply and a few only need be considered as they are necessarily local and special in their characteristics, may be considered the important matter of the purification of water supplies. That subject is of general interest to all communities.

#### PURIFICATION OF WATER SUPPLIES.

**Introduction.**—This is so important that it must be considered at some length and under several subheadings. Enough has already been said to show that nearly all waters in their natural or raw state are unsuitable for potable uses, but most unpolluted surface waters may be rendered wholesome. Under this subtitle some of the processes in use for that purpose will be described.

Purification of water supplies is no longer effected by the lyre of Empedocles as stated by Matthew Arnold, whose music did

"Cleanse to sweet airs the breath of poisonous streams."

Absolute self-purification of running waters has not been conclusively demonstrated, though partial purification is undoubtedly effected. (Consult Phelps, Earle B., 'Studies on the Self-Purification of Streams,' United States Public Health Service). Where oxygen from the air is dissolved in water oxidation of organic matter takes place and bacteria in time are destroyed provided such running water be not further polluted by sewage and other contaminating refuse. Where waters are covered with ice and oxygen is excluded therefrom, there may be an increase in their bacterial content. Prof. H. Marshall Ward has reported that the blue and violet rays of sunlight destroy bacteria near the surface but have little or no effect upon the germs a few feet below the surface. In darkness some genera are propagated. The *B. coli communis*, *B. typhosus* and others will live several days in running water and multiply therein, if there be waste material thrown into it.

To aid natural purification, "filter wells," "filter galleries" and "filter cribs" have been installed at some places in West Virginia, Pennsylvania, Indiana, Ohio, Massachusetts and elsewhere, which are of doubtful utility for they merely clear the water of visible pollution, while they may concentrate the bacteria and promote their propagation.

Polluted waters percolating into some soils are subjected to nitrification, which William P. Mason describes, as the tearing asunder of the objectionable nitrogenous organic materials, securing their union with the oxygen of the air and thus converting them into harmless inorganic forms. The action of nitrifying bacilli is mainly confined to upper layers of soil. Mason on 'Water Supply,' p. 221.

George A. Johnson of the United States Geological Survey says in his valuable Water Supply paper that "a majority of the cities and towns of the United States take their water supply from ground sources . . . and as a rule they are pure, clear and colorless, although they are very hard and others

contain much iron in solution." Recent bacteriological and microscopic examinations, however, show many ground waters and consequently wells and springs are not wholly free of pathogenic bacteria. All waters collected for potable purposes ought to be tested before they are used. Most of them in their natural state contain micro-organisms, some of which are pathogenic and others are harmless as stated by Dr. Maximilian Marsson of Berlin in his lectures on "The Significance of Flora and Fauna in Maintaining the Purity of Natural Waters." Each water supply from whatever source ought to be tested before use. Iron is found in the ground waters of Germany, Holland, the Netherlands, Britain, the United States and elsewhere.

In his valuable work entitled 'The Purification of Public Water Supplies,' John W. Hill, at page 278, says "the dimensions of the bacteria (*B. typhosi*) are stated in microns, designated by the Greek letter  $\mu$ , which is 1/1000 millimeter, equal to 1/25000 of an inch. Thus the typical dimensions of *B. typhosus* are .5 to .8  $\mu$  wide, by 1.5 to 2.5  $\mu$  long, or about 1/50000 to 1/31250 of an inch wide or thick and 1/16666 to 1/10000 of an inch long. Taking the average length of the typhoid bacillus as two microns ( $\mu$ ) it would require 12,500 of these placed end on end to make an inch."

All such bacteria are invisible and may be detected only by some one of the modern scientific tests. (Consult Hasseltine, H. E., 'The Bacteriological Examination of Water,' United States Public Health Service). Some bacteria are non-pathogenic and, with such knowledge as we now have of their characteristics, are considered harmless, while others are themselves destructive of lower bacteria, as are the *Rotifera*. Bacteriologists are studying these lower forms of life to determine their nature and activities in relation to other forms of animal life and are making new discoveries from time to time of vital importance to the welfare of the race.

**Bacteria and Other Micro-organisms in Water.**—Migula undertook to classify all bacteria into five families, namely, (1) *Coccaceæ*, (2) *Bacteriaceæ*, (3) *Spirillaceæ*, (4) *Chlamydo-bacteriaceæ* and (5) *Beggiatoaceæ*.

That grouping is still maintained by some bacteriologists. Other and additional families have also been suggested. Some species are pathogenic. Some bacteria already localized are *B. aerophilum*, *B. alcaligenes*, *B. anthracis*, also known as the *microspira comma bacillus*, the cause of anthrax, or splenic fever, *B. cloacæ*, *B. coscoroba*, *B. coli communis*, under certain conditions pathogenic, one of the widely disseminated microbes, *B. communitior*, *B. cuticularis sporogenes*, *B. diphtheriæ*, *B. enteritidis sporogenes* in sewage, *B. influenza*, *B. lepræ*, *B. pestis*, causing Bubonic plague, *B. prodigiosus*, *B. ruminatus*, *B. salmoni*, causing hog-cholera, *B. shiga*, found in cases of diarrhea, dysentery and cholera infantum, *B. simplex*, *B. streptococci*, *B. subtilis*, *B. tuberculosis*, *B. tumescens*, *B. typhosus*, *B. welchii*, *M. agilis*, *P. mirabilis*, *B. vesiculosi* and others.

Nearly all of these subsist in natural and polluted waters and increase rapidly under favorable conditions. Thousands of some of them have been found in a single cubic centimeter of raw water. They are found in

natural, unpolluted pools, brooks and ponds in rural and even in mountain regions. From official reports it may be seen how prevalent they are in nearly all waters and the processes that are being adopted to eliminate or destroy them. Some of these will be considered in this article. In 1906, S. D. Gage concluded that they propagate more rapidly in warm weather than they do in cold weather. Millions of some species have been found in a cubic centimeter of sewage, thus showing the danger of pollution therefrom.

In addition to the bacteria proper are the innumerable micro-organisms, comprising both animal and vegetative growths in drinking water. Prof. George C. Whipple has described and enumerated in his 'Microscopy of Drinking Water' 200 or more of such species. He has classified vegetative organisms into such groups as (1) *Diatomaceæ*, (2) *Schizophyceæ*, comprising *Schizomycetes* and *Cyanophyceæ*, (3) *Algæ*, (4) *Fungi* and (5) various higher plants. Under *Diatomaceæ* is the species *Asterionella*, which infested Mount Prospect reservoir in Brooklyn in 1897 and necessitated its non-use until they could be removed.

He has classified the animal micro-organisms into (1) *Protozoa*, comprising *rhizopoda*, *mastigophora* (flagellata), and *infusoria*; (2) *Rotifera*; (3) *Crustacea*, comprising *entomostrea*; (4) *Bryozoa*; (5) *Spongidae*, and (6) various higher animals.

Other sanitary engineers, biologists and bacteriologists have localized and classified other species, of which these may be legion. Some of these have been studied and subjected to various tests to determine their characteristics and their effect upon water and water supplies. Some live but a short time, while others live for days, weeks and even months. Some after brief existence die and impart a disagreeable taste or an offensive odor to water. Some genera are pathogenic, that is they produce disease in human beings and other genera are harmless, so far as known at the present time.

Prescott and Winslow in their 'Elements of Water Bacteriology' describe still other characteristics of some of the countless colonies of animalcula infesting the surface and ground waters of the earth. Bacteria are found in shallow wells and even in deep well waters. Prescott and Winslow found them in deep wells and springs in Worcester, Waltham, Hyde Park, Mass., in Newport, R. I., and at Saranac Lake, N. Y. They have been found in well waters at Mainz, Leitmeritz and Kiel in Germany and elsewhere. Quantitative bacteriological examinations and the microscope are now revealing bacteria in many waters not detected by any of the tests formerly applied, and that may account for the failure to discover them. Consequently bacteria in ground waters escape detection and such waters were formerly considered pure and wholesome. "Even rain and snow," say Prescott and Winslow in their 'Elements of Water Bacteriology,' "are by no means free from germs, but contain them according to the amount of dust present in the air at the time of the precipitation. . . . Janowski, in 1888, found in freshly fallen snow from 34 to 463 bacteria per cubic centimeter of snow water. . . . It is

difficult to find a river in inhabited regions, which does not contain several hundred or thousands of bacteria to the cubic centimeter.<sup>9</sup>

In ground waters are found such microscopic organisms as *crenothrix*, *cladothrox*, *lepothrox*, *asterionella*, *anaerobia* and typhoid bacteria. The latter were reported as occurring in some ground waters in Germany, probably due to surface pollution. Still many communities obtain their supply from surface waters such as springs, streams, rivers, ponds and lakes, all of which are fed primarily by the waters and snows, precipitated over the earth's surface to the extent already shown. Most of said waters are consumed in their natural state without purification by filtration, sterilization or otherwise. As already stated, it is a well-known fact that most surface waters are unsafe for potable uses. Such waters are frequently polluted by the inflow of sewage and become the purveyors of deadly organisms.

The investigation of the pollution and sanitary conditions of the Potomac watershed under the supervision of the United States Hygienic Laboratory reported in Bulletin No. 104 disclosed 20 or more genera of living organisms, including *bacilli coli communes* in great quantities. Spore-forming *anaerobia*, gas producing organisms, were found in parts of the river unpolluted by sewage, thus proving that those living organisms may be found in any surface waters. The biology of rivers has been treated by Dr. S. A. Forbes, Prof. R. E. Richardson and others in this country and by Dr. A. C. Houston in his 'Report on Research for The Metropolitan Water Board of London' and by W. G. Savage of England. The American Public Health Association in its report on 'Standard Methods of Water Analysis' in 1912, suggested tests to discover bacteria in water. Typhoid fever and other deadly diseases may have their inception from the bacteria in such unwholesome waters. It is, therefore, of vital importance to all communities, that they be provided with pure water supplies. This may be accomplished by treating such waters in a manner to rid them of bacteria and all other foreign organisms. Other bacteria will be mentioned under the several processes for their elimination.

The general acceptance of "the germ theory of disease" led to investigation into the media of transmission of pathogenic microbes. Potable water was found not only to be a purveyor of such bacteria but a medium for their propagation. The epidemic of Asiatic cholera in Europe in 1847 and in 1850 has since been attributed largely to contaminated water supplies. The British Parliament, suspecting that such might be the case, in 1852 passed its first act requiring the filtration of the Metropolitan Water Supply. Later Dr. Robert Koch actually discovered the cholera bacillus (*B. cholerae Asiaticæ* or *comma bacillus*) and found that it would exist for some time in water. He thereby demonstrated that cholera might be spread through water supply of communities, as it appeared to have been spread during the epidemic of 1847 and 1850. Upon the surface of an open sand filter at Boston six genera and four and one-third million organisms were found in one square centimeter of sand. All were not pathogenic but some are an aid to filtration. How-

ever when the decomposition of such organisms in water sets in, it may impart offensive odors. These have been grouped as aromatic, grassy and fishy, thereby indicating the genus undergoing decomposition and disclosing the character of pollution.

The most numerous and prevalent pathogenic microbes found in American and foreign surface waters are the typhoid bacilli, which caused a death rate of 23.3 per 100,000 population in 48 cities of the United States in 1910. That is four times the death rate per 100,000 population in Berlin, Vienna and London from typhoid fever per annum. But the death rate from typhoid in America is being lowered, as greater efforts are being made to secure pure waters for municipal and general potable purposes. Fortunately for rural populations most of their supplies are from ground waters, which are free or largely so from bacteria, except where such ground waters are near enough the surface to be polluted.

Dr. Koch discovered a method of eliminating bacteria from surface waters, which was to allow the water to percolate through slow filters. Those were found to remove most of the microbes from the water as it percolated through such layers of sand and gravel. A single filter, however, did not always arrest all the living organisms in the water, so that two or three sand filters came into use. The filter beds at first are not wholly impervious to the transmission of bacteria. It was learned from experiments that the surface must first be coated with a film of mud and microbes before the latter were entirely arrested. When such a film is completely formed over the surface of the layer of sand, then the filter is efficient and may be kept in operation as long as water continues to percolate through it. Then its layers may be washed by drawing off the water standing in the basin and by forcing filtered water up through the layers of sand and of coagulated matter. While the filtered water is being so forced up through the layers, they and the coagulated matter thereon may be agitated by raking as is done in the works of Pittsburgh, or they may be agitated by mechanical devices. In this manner the coagulated matter is lifted and freed from the surface of the sand. Filtration may then be resumed. This may be repeated once or twice before it is necessary to scrape off the coagulated matter and the upper layer of sand to the depth of one or two inches, which is all that is necessary to remove, in order to dispose of the pathogenic microbes and other foreign bodies and the mud and silt. The layers of sand so removed may then be cleansed, dried and replaced in the filter basin and filtration may be resumed. There are various methods of renovating sedimentary and infiltration basins, but the foregoing methods illustrate some of the processes in general use. It is a well-known fact that bacteria propagate rapidly and there is always a possibility that some may pass through a filter and contaminate the water that has passed through such filter.

The processes in general use for the purification of water include: (1) Sedimentation with or without chemicals; (2) preliminary treatment for slow sand filters; (3) slow sand filtration; (4) rapid sand filtration; (5) the dis-

infection of water supplies by various chemicals; (6) the application of (a) ozone, or (b) ultra-violet rays of light, and (7) by sterilization. Two or more of these processes may be used in succession in the same plant, or they may form parts of a single system though operating independently of each other.

In the application of these processes many subsidiary details are involved and the completed waterworks of a city are often its most costly, complex and elaborate public works.

A brief description of each of these several processes for the purification of water may show something of their value and adaptability to the services which they are required to perform in rendering water suitable for domestic and potable purposes.

1. Sedimentation is the clarification of turbid or of other waters holding particles of foreign matter in suspension. This may be aided

at Cincinnati and Covington; Dr. A. C. Houston reported to the London Metropolitan Board that "thirty days' storage of river-water is tantamount to sterilization" as to pathogenic microbes. William P. Mason, however, states that "bacteria sink but slowly in water." If that be so, a long period of subsidence is necessary to make sedimentation an efficient process for their removal from water supplies.

2. The preliminary treatment of water for slow sand filters may be affected by the use of sulphate of lime to coagulate the clay particles in suspension as in the Potomac, or by the use of concrete sedimentation basins with roughing filters of coarse stone, called baffles, to strain out the coarser materials in some waters coagulated by the introduction of chemicals and removed therefrom before the water passes into the sedimentation basins, as in the filtration plant at Pittsburgh, or still by the use of such prelimi-

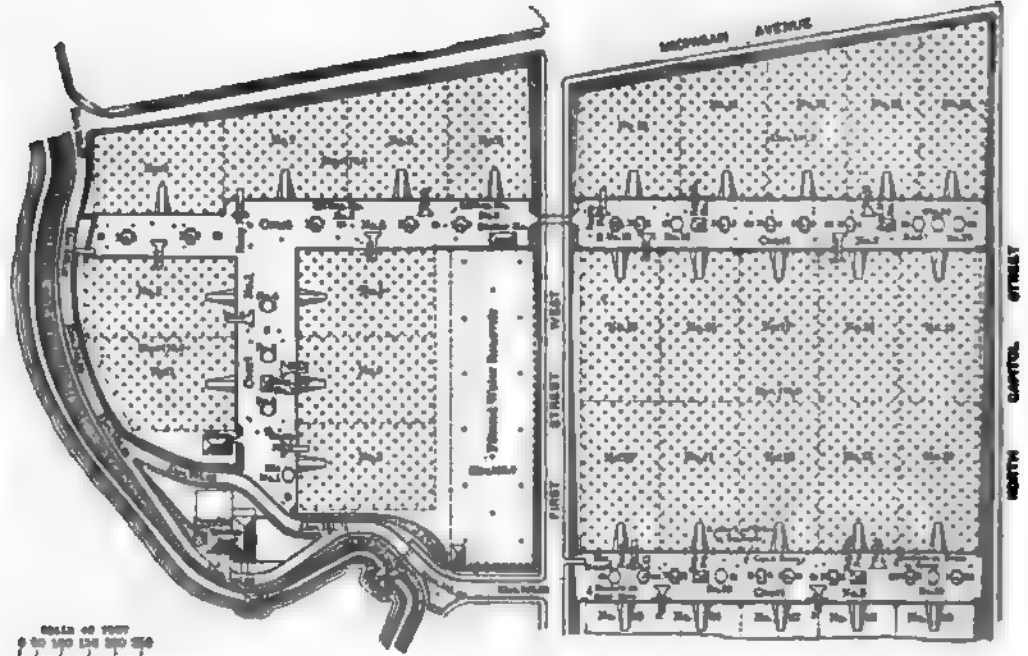

FIG. 1.—General Plan of Filtration Plant, Washington, D. C.

by the introduction of such chemicals as tend to promote coagulation of the particles in suspension in the water. Sedimentation is the process used in the removal of such large particles as are found in the waters of the Hudson above Poughkeepsie, in those of the Potomac above Washington, in the Ohio above Cincinnati and Louisville and in the Mississippi above New Orleans, in all of which cities sedimentation reservoirs and coagulation basins are in use. The process removes most of the colloidal material in suspension. Percy Frankland found that sedimentation removed 82 per cent of the bacteria in the Grand Junction Company's reservoir and about 87 per cent of the bacteria from the water that had passed through to storage reservoirs of the West Middlesex Company. Official reports show that from 87 per cent to 97 per cent of the bacteria were removed from the waters after 32 days subsidence in the reservoirs

many filters without coagulation, as those of the Torresdale type in use at Philadelphia, where since their installation it has been found necessary to install a sedimentation basin for the use of coagulants on account of the large quantity of turbid waters to be treated, or still by the use of such prefilters as those described by William F. Johnson, in the Puech-Chabal system extensively used in Europe. That system consists of a series of decreasing in size roughing filters, a subsiding basin and a coagulating basin.

3. The slow sand filtration process is in use in Washington, D. C. A large area of sand is required and many water-tight basins of sand are necessary, where a large volume of water is to be clarified. The Belmont and Queen Lane filters of Philadelphia are of this type and comprise many shallow sand beds underlain with layers of gravel. Such filters

have masonry or concrete walls and are covered over where necessary to prevent freezing. Philadelphia has five slow sand filtration plants, known as the Upper and Lower Roxborough, Belmont, Torresdale and Queen Lane plants, with an aggregate daily capacity of 405,000,000 gallons, the largest in the world. Some of these have settling basins, sedimentation basins, covered preliminary filters, filtered water reservoirs, the Torresdale plant of 240,000,000 gallons daily capacity having 120 covered mechanical preliminary filters. Philadelphia obtains its supply from the Schuylkill and Delaware rivers and the latter is becoming so polluted, that other sources may be required. The arrangements there for treating water with chemicals were elaborate and it was necessary to use chlorine, for the Torresdale filters did not remove all the bacteria.

From Hugh S. Cumming's 'Investigation of the Potomac Watershed,' it appears that the District of Columbia obtains its supply of water from the Potomac River at Great Falls 150½ feet above tide-water. The water is conducted through a circular conduit nine feet in diameter most of the 15 miles distance by gravity to the Dalecarlia, Georgetown and McMillan Park reservoirs, from the latter of which the water is pumped up 21 feet to the slow sand filtration plant, one of the best in the country, comprising 29 filters, each having an area of an acre, altogether having a daily capacity of upwards of 100,000,000 gallons. In the Georgetown reservoir the water is sometimes treated with sulphate of aluminum, used as a coagulant to assist sedimentation before slow sand filtration and in some cases it is used where no filtration is employed.

Plants for supplying such preparation of alum as a coagulant have recently been installed at Trenton, N. J., Springfield, Mass., Columbus, Ohio, and at Omaha, Neb. Slow sand filters were used by the Chelsea Water Company of London in 1829 to remove turbidity from water. As now constructed their daily capacity is from 2,000,000 to 3,000,000, and in some exceptional cases as high as from 6,000,000 to 8,000,000 gallons per acre. When they become clogged, as they necessarily do, then the coagulated deposit is removed. Then the superficial layers of sand from one-half to one and one-half inches in depth are scraped off, then washed and dried and replaced. There are several means for sand washing, including the Nichols separator, the Blaisdell filter sand-washing machine and surface raking, which increases the efficiency of the process of slow sand filtration. In all such plants at least 12 inches of sand must be maintained and from two to three feet of sand is much more efficient. Many cities and villages are using the slow sand filtration process for the filtration of water, including New Orleans, Pittsburgh, Superior, Zurich, Yokohama and Osaka, where in 1905, the bacteria were reduced from 200 to 25 per cubic centimeter, while at Lawrence, Mass., the bacteria in the Merrimac River water were reduced from 12,700 to 70 per cubic centimeter as a result of the installation of the slow sand filtration plant there in 1893. The chlorine disinfection of that water was reported on by Clark and Gage in 1909, showing the reduction of bacteria at different temperatures of the water. Such plants are at

Albany, N. Y., and at Wilmington, Del., and many are in use in Europe. Some of them are equipped with automatic controllers. The rate of filtration is slow and the filter must be cleaned and that is done by scraping off the superficial layers of sand and then washing, drying and replacing them. Allen Hazen says that "sand filtration alone, without preliminary treatment, is able to remove nearly all of the objectionable bacteria, as well as other organisms, from many waters, at the same time purifying them in other ways." The bacterial content of the filtered water is very low, but not entirely free from organisms. It was on the report of James P. Kirkwood of his investigations in Europe in 1866, that Slow Sand Filtration plants were subsequently constructed at Poughkeepsie, Lowell, Columbus and Toledo.

4. Rapid sand filters, by some also denominated mechanical filters, require less area than do the former type, but they are more elaborate and somewhat complex in construction. Typical plants comprise pumping stations, preliminary settling basins, coagulation basins for the treatment of the waters by chemicals, chemical rooms and mixers, filter tanks with connecting pipes, cleaning apparatus, controlling mechanism, covered reservoirs for the filtered water, a drainage system and other equipment to meet existing conditions, as to locality, characteristics of raw water and amount of filtered water desired. Filters of this type will clarify 125,000,000 gallons of water a day per acre of its turbidity and of 90 per cent to 99 per cent of its bacteria. Strictly modern rapid sand filter plants under skilful management with the proper use of germicidal chemicals are nearly 100 per cent efficient in the elimination of all bacteria from ordinary running surface waters. Some waters, however, carry in solution an abnormal amount of foreign substances and those may partially neutralize the germicidal agents of the usual dosage and in such cases the bacterial content may not be entirely negligible. In such cases the foreign matter may partially consume the disinfectant, so that some of the bacteria may escape and appear in the effluent. Such effluents may then be treated with chlorine, which will destroy the remaining bacteria, unless they be of a class immune to such treatment.

Rapid sand filters of the improved type are in use in Little Falls, N. J., Cincinnati, Columbus, Cleveland, Youngstown and Toledo in Ohio, Louisville, Ky., Saint Louis, New Orleans, Harrisburg, Minneapolis, Baltimore and elsewhere. The Cincinnati, Louisville, New Orleans and some others also have preliminary settling basins, where the suspended colloidal matter in the water settles. The water is then drawn off into the coagulation basins and therein coagulation is effected by the introduction of common alum, or aluminum sulphate alone or with caustic lime or ferrous sulphate (copperas) or other chemical coagulant. When brine is used in some cases caustic alkali is also needed.

Joseph W. Ellms, author of 'Water Purification' states that "such electrolytes as acid basis and salts will coagulate colloidal suspensions and so will hydrochloric acid, caustic soda, caustic lime or ordinary salt solutions." In that manner all organic matter including bacteria and inorganic matter suspended in the

water are entangled and deposited on the layer of sand at the bottom of the basin. The bacteria and colloidal matter so deposited form a coating, or film over the surface of sand impervious to bacteria and other suspended matter but not so to water, which flows rapidly through it. Many devices serve to facilitate the operation of that process of the purification of the raw river waters, which are the source of supplies for such cities.

Rapid sand filtration operates rapidly, owing in part to the reverse flow of water through the sand, which flow washes away the accumulation of coagulated matter and bacteria into the drainage pipes. Several hundred cities are using this process for the purification of their waters, including many foreign cities. The bacteria in the Polar River water at Bethmangalia, India, were reduced from 4,350 to 13 per cubic centimeter.

The construction and operation of the rapid sand filtration plant at Baltimore will suffice to illustrate that process of purification of water supplies.

Baltimore formerly obtained its water supply from Gunpowder River, collected into Loch-Raven and from Jones Falls collected into Loch Roland. Both sources were polluted by pathogenic bacteria, including *B. typhosi* and *B. coli communes* in great quantities.

Baltimore still obtains its principal water supply from the new impounding reservoir at Loch Raven, which has been enlarged by a new dam 48 feet above the bedrock. The water is drawn through a tunnel 12 feet in diameter into Lake Montebello and from that lake it is pumped through a venturi meter, an aerator gate house, head house with tower 80 feet high containing chemical storage bins, a mixing basin, coagulating basins and thence to the filters. The design involves the handling of wash waters in the settling reservoirs, a drainage system, effluent pipe details, a head house, a pumping station, a baffle mixing chamber, two coagulating basins, covered filtered water reservoirs and other equipments.

A nine-foot conduit, recently built, connects the Montebello reservoirs with the distributing system at Lake Clifton. Altogether the Baltimore new mechanical filtration plant, also known as the rapid sand filter, at Lake Montebello, has 32 units, each with a capacity of 4,000,000 gallons daily.

5. The disinfection of water supplies by various chemicals. In 1774 the Swedish chemist, Karl Wilhelm Scheele, made an analysis of manganese dioxide and from that he was led to the discovery of chlorine. Hydrochloric acid, consisting of chlorine and hydrogen, was isolated by J. Priestley in 1772. Chlorine depends upon the oxidation of that acid, whose salts are known as chlorides. In 1800 chlorine was used as a disinfectant in France and in England. In 1854 it was used in London to deodorize sewage. Another chlorine disinfectant was Eau de Javelle made by Percy, near Paris in 1792, also known as Labarraque solution, chloros and chlorozone, according to Joseph Race. The germicidal nature of chlorine, however, was not understood until after the discovery of living organisms in water. Experiments were made with chlorine in

France, England, Germany and in the United States. In 1890 a plant was erected for its manufacture at Bradford, England, and in 1893 one was erected at Brewster, N. Y., and "electrozone" was applied to the sewage then polluting the Croton water supply. Dr. A. C. Houston of London is said to be the first to apply chlorine to the purification of water. The history of disinfectants now very widely and generally used is given to show the slow progress made in the evolution of such agencies for the purification of water supplies. Had chlorine been in general use within half a century after its discovery, the appalling mortality in London in 1854, due to cholera, and in Germany in 1892-93, also due to cholera, might have been avoided.

The chemicals now in use as such disinfectants are liquefied chlorine gas, calcium hypochlorite or bleaching powder, sodium hypochlorite, copper sulphate in minute quantities, sulphate of ammonia, sulphate of iron, caustic and hydrated lime, carbonate of soda, chloramine and possibly others or compounds of some of these. Most of these germicides are of recent discovery and their application to water supplies has necessitated the renovation of most of the water plants of this and other countries. Since the proposal of Webster in 1889 to use electrolyzed sea-water as a disinfectant, several processes have been utilized for the transmission of a current of electricity through some of the foregoing and other substances to produce coagulants and disinfectants.

In 1859 James Watt discovered that hypochlorites were produced by the electrolysis of the chlorides of alkalis and alkaline earths.

Joseph Race, in his 'Chlorination of Water,' p. 106, maintains that in the electrolysis "of the solution of sodium chloride, the chlorine may combine with the sodium hydrate formed by the action of the sodium on the water to form sodium hypochlorite, one-half of the chlorine produced is found as hypochlorite and the other half reforming sodium chloride. . . . The electrolytic hypochlorite method offers some advantages, but in the great majority of plants it cannot economically compete with bleach."

Commercial bleaching powder is formed by passing chlorine gas over slacked lime. It is also known as calcium hypochlorite and as stated by Joseph W. Ellms in his 'Water Purification,' p. 369, consists of several chemicals formed by the reaction of chlorine and calcium, such as calcium oxychloride, calcium chloride, calcium chlorate, calcium hydroxide, calcium carbonate, calcium sulphate, oxides of Na.K.Mg.Fe and Si. and moisture. These undergo reactions resulting in the evolution of oxygen which is set free and is destructive of micro-organisms. Oxygen is the potential energy that destroys them.

Calcium hypochlorite was first used effectively in this country to purify the waters of the Benton reservoir at Jersey City of bacteria. Since that it has been and is still extensively used as a disinfectant. Its germicidal energy is said to equal ozone as an oxidizing and sterilizing agent, and is much cheaper than ozone.

Hypochlorite of sodium, obtained by the

electrolysis of salt, has some advantages over hypochlorite of calcium, which produces sludge, that clogs orifices and is dangerous to fish, when dumped into running waters.

Joseph Race, in his 'Chlorination of Water,' p. 17, says that "on dissolving bleach in water the first action is the decomposition of calcium oxychloride into an equal number of molecules of calcium hypochlorite and calcium chloride." At page 20 he says: "The addition of small quantities of sodium chloride (0.1 per cent) increases the hydrolysis of bleach solutions but much larger quantities tend to the opposite direction . . . . Sodium chloride in the absence of hypochlorites was found to have no influence upon the viability of *B. coli* in water."

Bleaching powder is one of the most efficient germicidal agents. The neutralizing chemical for an overdose of bleaching solution is sodium thiosulphate at one-half the amount of the former.

F. Raschig, Samuel Rideal and Joseph Race have developed the new germicide, known as chloramine ( $\text{NH}_2\text{Cl}$ ), formed by adding ammonia to bleaching solution, which increases the germicidal action of the latter. Joseph Race has stated that from numerous experiments he concluded that the most efficient proportion of the compound was two parts by weight of chlorine to one part by weight of ammonia. Consult Race, J., 'Chlorination of Water' (p. 118).

On a recent inspection of the operation of the chloramine process at Ottawa, the author learned that the after-growth noted after the use of hypochlorite in some plants amounting to 20,000 bacteria per cubic centimeter has been eliminated and that the *B. coli communis* had been nearly all destroyed. Race reported that similar results followed the application of chloramine at the Capitol Hill reservoir in Denver, where bacteria dropped from 15,000 to 10 per cubic centimeter. It is important to the health of a community that some process be adopted that will eliminate or destroy pathogenic bacteria, so that less than 100 bacteria per cubic centimeter survive whatever process of purification that community may adopt. Otherwise, its water supply is not of that degree of purity which hygienic standards require for potable uses. Such standards have been greatly raised in the last half century, and no enlightened community would be suffered to use such water supplies as were in general use before the nature and characteristics of the micro-organisms in such waters were discovered and partially understood. Therefore the modern processes for the purification must be efficient, and to be so they must conform to scientific standards. Communities will not be permitted longer to provide water laden with pathogenic microbes, and if any one of the foregoing processes of purification fail to eliminate or destroy such organisms, then it ought to be superseded by the installation of a more efficient process, as was done at Ottawa by the substitution of the chloramine in place of liquid chlorine.

Lieutenant Nesfield of the Indian Medical Service is said to have used liquid chlorine gas as a disinfectant of water in 1903. Since 1910 liquified chlorine gas has been used in several cantonments of the United States army and at Wilmington, Philadelphia, Brooklyn, New York and in many other places. On the Western Front during the Great World War

it was successfully applied by means of liquid chlorine machines. The Dunwoodie chlorinating plant for New York City has a daily capacity of 400,000,000 gallons. The chlorine gas is introduced into the water in the aqueduct as it leaves the Kensico reservoir to ensure practical sterilization of the water before it reaches the city of New York. This process has some advantages over the hypochlorite or ozone process, though there is danger of injury to operators from leakages of the gas, which is injurious to the lungs and deadly if inhaled in concentrations of .06 per cent. The relative efficiency and cost of installation of these several processes are usually considered before any one is installed. Recently halazone ( $\text{C}_2\text{N}_2\text{O}_2\text{S}_2\text{C}_6\text{H}_4\text{COOH}$ ) has been found to be an efficient chemical for sterilizing heavily polluted waters.

6. The Application of (a) Ozone, or (b) Ultra Violet Rays of Light.—(a) "Ozone is produced," says Allen Hazen in his 'Clean Water and How to Get It,' p. 101, "by the discharge of high-tension electricity through air under certain conditions. The air is afterward pumped through the water to be treated or otherwise the water is showered downward through towers in which the ozonized air is circulated." Ozone, being a modification of oxygen, is a more active oxidizing agent than oxygen and is a powerful disinfectant. There are many devices for the application of ozoned air to the purification of water, but the process is equally efficient but more expensive than the application of the chemicals hereinbefore described. The De Frise system at Saint Maur gives satisfaction in sterilizing the Marne water after sedimentation and filtration. Sanitary commissions, health authorities and specialists have extensively experimented with it in Europe and found ozonized air, when properly applied, was destructive of bacteria in water. The application of the ozonized air produced by the ozonizers, of which there are several in use, such as the large plant of 128 Siemens and Halske ozonizers at Petrograd, with five sterilizing towers, is as follows:

The ozonized air enters the bottom of water towers and is absorbed by the water as it descends through the layers of gravel in some and sieves in other towers after the water has first passed through sedimentation and preliminary sand-filter basins. Such water as it enters the sterilizer may still contain several hundred bacteria per cubic centimeter. The pathogenic bacteria, such as typhoid and cholera microbes, are destroyed by ozonized air, though the more hardy and harmless ones may escape destruction. In the higher towers, the sterilizing ozonized air is injected at several levels, as at Ginnekin, Holland, where all pathogenic bacteria are destroyed. The process is more costly than the hypochlorite process, but it has been pronounced by an English expert as "ideal." It is in use in Brussels, Ginnekin, Paris, London, Berlin, Petrograd, Florence, Chartres, Nice, Saint Maur, Wiesbaden, Paderborn and in many other European cities, and at one plant in Philadelphia and in Ann Arbor, Herring Run, Md., and a few other places, but it is not at present extensively used in America. It has some advantages over the chlorine processes. The Otto process in use in Nice purifies 5,000,000 gallons daily. Its general

use in Europe, after most thorough tests as to its efficiency, may result in its more general use in America.

(b) Ultra-violet rays of light. One of the recently discovered processes for the destruction of pathogenic bacteria is the application of ultra-violet light to the flow of water through flumes, so that the organisms are exposed to the concentration of its rays. Several ultra-violet ray sterilizers have been devised and successfully used in the rapid destruction of bacteria. It was demonstrated, by experiments made by Henri Helbronner and others at Sorbonne University in Paris, that bacteria cannot long endure the direct ultra-violet rays of three ten-thousandths of a millimeter in length. American tests have shown that it required only one-twentieth of a second to kill bacteria with such rays, but they must not be intercepted by suspended organic matter in the water. It is, therefore, necessary that the water be rid of turbidity before applying the ultra-violet ray process to its sterilization, for Dr. Von Reckling-Hausen declared that it is the light and not chemical reaction that produces the germicidal results. Ultra-violet ray tests made at Luneville, France, on water containing 60,000 germs per cubic centimeter reduced the number to 10 germs per cubic centimeter and destroyed all *B. coli*. The death rate of 70 to 160 of typhoid fever also became negligible. Since devastations of the Great World War began, the water supply of northern France has been contaminated at the rate of 4,600 putrescent bacteria and 1,000 *B. coli* per cubic centimeter and they may go on for years in an increasing ratio, in consequence of the countless burials and pollution of the underground waters of the war zone. The Quartz-Mercury lamp is sometimes used to produce ultra-violet rays for the sterilization of water. That process eliminated nearly all the bacteria from the raw Durance river water at Marseilles.

7. By Sterilization.—Purification is also generally effected by sterilization, which is used in conjunction with several of the processes already mentioned. By reason of the various chemicals used and their germicidal action on micro-organisms, irrespective of the other agencies employed, too much attention cannot be given to the process of sterilization.

In recent years some public water supplies have been purified by sterilization, where sewage bacteria now known as *anaerobic spore-forming bacilli*, including *B. aragenes capsulatus*, *B. enteritidis*, or *B. sporogenes* and *B. streptococci* were present. Active agents were necessary to destroy them. The basins or reservoirs where the process of sterilization is in operation must be cleansed two or more times a day.

In 1892, the English employed calcium hypochlorite to disinfect sewage. In the following year the American Public Health Association recommended its use as a disinfectant. It was known in 1892 that hypochlorites were efficient water sterilizers. In 1897 they were first used at Maidstone, England, to purify its water supply, after a typhoid epidemic. In 1904 they were applied to disinfect the water pipes in London. Thereafter they came into quite general use in this and other countries. Hypochlorite of lime and hypochlorite of soda are

the principal chemicals used. Where hypochlorite of lime is used its solutions are thoroughly mixed with the raw water in the proportion of 5 to 10 pounds of the powder to 1,000,000 gallons of water, which is destructive of such pathogenic germs as typhoid, cholera and other bacilli. The objection to this chemical is that a sludge is formed, which interrupts the flow through the orifices and is also injurious to aquatic life, when deposited in fresh waters. Hypochlorite of soda, electrolytically produced, is somewhat more destructive of pathogenic bacteria than hypochlorite of lime. It is not difficult to produce and does not form sludge. The hypochlorites, however, are not a substitute for filtration, but rather additional agencies, that may be used to ensure complete destruction of pathogenic germs. Some spore-forming bacteria in water are not pathogenic and not all of these are destroyed, because they are hardy and not affected by any of these chemicals, when in such small proportions as not to affect the water deleteriously, but made sufficiently active to destroy pathogenic germs, which are less hardy. Many cities in this and in other countries use the hypochlorite processes in connection with sedimentation and filtration.

Francis F. Langley reported (*American Journal Public Health*, 4 Dec. 1914) that two billion gallons of water per day were being treated with bleaching powder, or chlorine gas. As already stated, liquid chlorine being the liquefaction of chlorine gas, produced by the electrolysis of sodium chloride in the manufacture of caustic soda, is also used to sterilize water supplies. There are several devices for applying the gas, which is eliminated from the liquid by heat, to the tanks of water to be treated. The gaseous vapor is diffused through the water and destroys the pathogenic germs. Some of the chlorinated water so sterilized in the tower of Wilmington contained only from 6 to 50 bacteria per cubic centimeter. Liquid chlorine is one of the sterilizing agencies used in Chicago Stock Yards, at Philadelphia, Pa., Saint Louis, Mo., Trenton and Newark, N. J., Cincinnati, Ohio, Niagara Falls and Ossining, N. Y., Hartford and Stamford, Conn., Saint Catharines and other places in Canada and at Honolulu, Hawaii, and elsewhere.

The ferrochlorine process of sterilization has been tested in Paris and found to be an efficient bactericide, though on account of its cost it is not in general use. Another sterilizing chemical was proposed in the form of copper sulphates, but that has not been generally adopted. It was proposed as a sterilizing process to dispose of microscopic organisms. The research work of the Bureau of Plant Industry of the United States Department of Agriculture, D. D. Jackson in his work on 'Odors and Tastes of Surface Waters,' and especially George C. Whipple, department engineer under the Burr-Hering-Freeman Commission, on the Additional Water Supply of New York City, and others have called attention to algae, and *spore-forming diatomacea (diatoms)*, or *bacillariae*, now classified as vegetative organisms, varying in diameter from one thousandth of a millimeter to one millimeter. Several species of these microscopic organisms are found in fresh waters. Several species

of *Anopheles* have been localized in the waters of Alabama, South Carolina and North Carolina by Dr. H. R. Carter and others of the United States Public Health Service. *Anopheles* are the cause of malaria. Mosquito-eating fish are being introduced to rid such waters of the *Anopheles* larvae.

Dr. Zacharias has identified the animalcula known as *flagellata*, which multiply rapidly and discolor surface waters. *Rhizopods*, including *amoeba*, *diffugia* and other genera; and *infusoria* which are the highest type of *Protozoa*, are also microscopic. Some are free-swimming and others attached animalcula. They exist in countless colonies and some of them are internal parasites. These infest reservoirs and other potable waters. The larvae of *chironomus* are found in upper layers of sand of waterworks in great colonies. Green and blue *algæ* known in Germany as "water blossoms," *scoglae*, *beggiatoa* and innumerable other micro-organisms infest waterworks, form slimy organic patches and undergo putrefactive changes. These decompose and produce odors and give water an unpleasant taste. George T. Moore and Dr. Karl F. Kellerman of the United States Department of Agriculture recommended the use of copper sulphate, but that does not always destroy all the typhoid bacilli and is a dangerous chemical to use, except in the smallest quantities, and when so used it is less efficient than the chlorides. Therefore it has not come into general use.

Nearly all the processes of sterilization are of recent discovery and those in general use are ridding potable waters of most of their pathogenic bacteria. Prior to their discovery half a century ago, they were the causes of epidemics that wasted away communities and historians referred to them as pestilences and plagues. It may be assumed that polluted water has destroyed as many human lives as the wars of all the ages.

Progressive nations are fast coming to realize that impure water is one of the greatest known menaces to health and to life itself. In this modern era the researches of scientists and experiments by health authorities have demonstrated that most pathogenic bacteria and nearly all living organisms in surface and other waters may be eliminated therefrom and all such waters may be made safe for potable and all other uses.

Communities are no longer limited to lakes, mountain streams, springs and other ground sources for their water supply, but may draw raw water from rivers, streams, lakes and ponds provided such waters be treated by some of the processes heretofore mentioned, that will render such waters pure and wholesome, as is being done by scores of cities in this and other countries. The water supply of a community is now largely a matter of purification, and while turbid or bacteria-laden waters are not desirable on account of the expense involved in carrying on the processes of purification, still if other adequate sources be not available, river and other surface waters may be made safe for potable purposes. Thus it is possible for communities to obtain their supply from nearby surface waters.

The Hudson, the Ohio, the Mississippi, the Niagara, the Saint Lawrence, the Thames, the

Seine, the Rhine, the Rhone, the Elbe, the Danube, the Volga, the Nile, the Ganges, the Irrawaddy, the Yangtse-Kiang and scores of other rivers, as well as the Great Lakes in North America, the British, Swiss, Italian, African and innumerable other lakes are the sources of the water supply for millions of population. When such waters are scientifically treated by some of the processes hereinbefore described, they are safe and palatable. The importance of preserving all such surface waters from artificial contamination has led to the enactment of many laws to prevent such contamination. In America and Europe water supply authorities are usually empowered to acquire catchment areas and in some instances large parts of watersheds to prevent artificial contamination as well as to procure additional sources as has been done by New York City in acquiring the Catskill watershed and certain British cities in acquiring large additional areas to ensure wholesome water supplies. Rather slowly the public conscience is being enlightened and awakening to the dangers of the contamination of water supply sources, in permitting the inflow of sewage, effluents from industrial plants, gas refuse, chemical works and other artificial wastes, all of which pollute and render waters noxious in their natural state. Most of these, however, are susceptible of such treatment as to ensure their wholesomeness for potable purposes.

The introduction and general adoption of scientific processes for the purification of water for municipal and domestic purposes hereinbefore described and others have necessitated the discontinuance of the use, or the demolition of many old and the installation of many new waterworks in this and other countries. The needs of each community and the physical conditions of the territory of each whence its supply must come, as well as the water sources themselves, become matters of public investigation and of scientific study. This was demonstrated in the undertaking on the part of the city of New York to obtain its additional water supply, commencing in 1896 and continuing for 20 years or longer. Such progress has been made in the scientific treatment of water for municipal purposes, that, in addition to a score or more of processes for its purification in most any state, its acidity may be neutralized, as at Mossley, England, it may be softened by any one of several processes, or it may be hardened and it may be deferrized as in Germany to get rid of the microscopic crenothrix and other bacteria absorbing iron into their tissues and closing water mains.

In all these matters conditions differ and it is necessary to specialize in the treatment of each municipal water supply. No two are identical, unless they form parts of the same system, as now does the supply for several boroughs of New York City, when the same general principles may apply, as to the collection, purification and distribution of water for such boroughs. But in most cases, each supply must be studied independently of all others and provided for, with special reference to its peculiar characteristics, which are as variable as earth's watersheds.

**Removal of the Salts of Calcium, Magnesium, Iron and Manganese.**—In some well

and other ground waters such minerals as salts of calcium, magnesium, iron and manganese are found in solution. An artificial zeolite, known as "Permutit," was produced by Dr. Richard Gans and is used to rid water of its calcium and magnesium. Caustic soda, the silica of sodium, barium carbonate and other chemicals are also used for that purpose. The Reisert zeolite and other water softeners are in use in this and other countries. C. P. Hoover and R. D. Scott in Ohio, R. N. Kimmard, Dr. Edward Bartow, Samuel A. Greeley, Francis G. Wickware and others have written on the subject of water softening by the "Permutit" or other processes. There is a large plant for softening at Winnipeg, Canada, and smaller ones at Oberlin, Ohio, and elsewhere in the United States.

The extraction of iron and manganese has also been studied by Dr. Gans, M. S. Applebaum, Dr. H. Luhrig, Frank E. Hale, R. S. Weston, F. C. Amsbary and others. Plants for deferrization of water have been installed at Middleboro, Mass., at Rotterdam, at Dresden, Breslau and Hamburg in Germany and elsewhere. The process is described in the reports of those specialists and is generally effective in eliminating those minerals from such waters, though there may remain in water pipes the *crenothrix*, *cladotrix*, *clonotrix*, *chlamydotrix* and *gallionella* organisms that flourish in such solutions. Karl Kraepelin found 60 species of animalcula, infesting the water pipes of Hamburg and known as "pipe moss" comprising sponges, *spongilla fluviatilis* and *lacustris*, *molusca*, snails, "water lice," *asellus aquaticus*, "water crabs" (*Gammarus pulex*) and other species. Rotterdam, Boston and Brooklyn have encountered troublesome growths in their water pipes.

**Minor Processes.**—Some of the minor processes of purification involve the use of the small mechanical filters, consisting of small basins of layers of sand, over which gelatinous films of aluminum hydrate are found. Water passes through these rapidly and the bacteria are caught in gelatinous material and removed. Such filters are used to clarify muddy waters during freshets and in limited areas, where sufficient land cannot be economically obtained for sedimentary and the slow sand filter beds. There are several hundred in use in America. Where properly constructed and operated, satisfactory results are obtained, but they must be cleansed twice or more times a day and the chemicals used in sterilization are expensive. Several such filters, including the Candy and Reisert types, are in successful operation.

The Lawrence filter first installed in the United States was the forerunner of other mechanical filters, that have proved quite efficient in purifying municipal water supplies.

**Porcelain Filters.**—Prof. Louis Pasteur and others have suggested porcelain and baked infusorial earth, as additional safeguards, but the necessity of their frequent sterilization and the cost of such filters render them impracticable for general water-supply purposes. Bacteriologists now contend that microbes are propagated in and are not eliminated by porcelain filters. There are other minor processes for the purification of water, such as granular bed filters, charcoal filters, porous wall filters, Berke-

feld system, Maignen method and the boiling of water. None of these processes are efficient in disposing of all the pathogenic bacteria. Some of these, such as *B. anthracis* and its spores, *B. typhosus* and others, are very persistent and live a long time in water. H. D. Fisher, Prof. John Tyndall and French and German bacteriologists have insisted that the boiling of water at 212° F. does not destroy the spore-bearing bacteria, though it may and does destroy many other species.

#### COLLECTION, IMPOUNDING AND DISTRIBUTION OF WATER SUPPLIES.

In the collection, impounding and distribution of water for water-supply purposes, a few systems will suffice to illustrate how many operate. As already stated, many communities obtain their supply from ground waters by means of wells and springs.

Batavia in the East Indies, notorious for its unhealthfulness, supplies its 240,000 inhabitants from ordinary wells. Many ground waters are polluted by surface waters.

Amsterdam derives its supply from open canals containing the waters collected from sand dunes and also from the river Vecht. Such waters are filtered. Antwerp derives its supply from polluted river water, which is treated and also filtered.

Rotterdam obtains its supply from Maas (Rhine), which is then filtered.

Magdeburg and Altona obtain their supplies from the Elbe, which are treated and filtered. Breslau obtains its supply from the Oder, Budapest from the Danube, Petrograd from the Neva, and Warsaw from the Weichsel River. All such raw waters are filtered and some, or all of them, treated with germicidal disinfectants.

Constantinople obtains its supply from streams, springs and forest catchment areas, where the waters are collected in impounding reservoirs and conducted in aqueducts to the city.

Damascus obtains its supply from the Abana River through conduits, which also convey water for power purposes. See Syria in article on RAINFALL.

Jerusalem obtains its water from springs, cisterns and pools, fed by conduits bringing water from Ain Saleh and other distant springs. Water from the Virgin Fountain flows through a tunnel to the Pool of Siloam.

In Phœnicia near Tyre were waterworks, consisting of towers, into which the artesian well waters flowed upward to a height of 20 feet or more above ground. Those waters were then conducted into reservoirs for the supply of that ancient port.

Berlin, Germany, obtains most of its water from deep boreholes near the shores of Lake Tegel, an expansion of the Havel River, and from Lake Muggel, one of the expansions of the Spree. These contain some iron in solution, as do most ground waters of Germany. It also obtains part of its supply from wells, since it has succeeded in eliminating iron from its ground waters.

The Spree was said to contain 2,500,000 more bacteria per cubic centimeter below Berlin than it contained above Berlin.

In 1878 *crenothrix* was found in the raw

water of the Spree and in wells at Charlottenburg. Dr. Richard Gans' new method and Herr Piefke's process were used to eliminate the iron and the bacteria, such as *crenothrix* and other micro-organisms dependent thereon. There are 60 or more sand filters with an aggregate area of 35 or more acres and other processes used to purify daily 66,000,000 gallons of water which is pumped into the city. The bacterial reduction in 1900 was from 896 to 27 per cubic centimeter in Muggelsee Works and from 345 to 22 per cubic centimeter in the Tegeler Works. There the death rate from typhoid fever and other diseases traceable to pathogenic bacteria is low. A new testing station of its water supply and sewage disposal is maintained in Berlin. In 1911 Berlin daily consumed 22 gallons for each of its 2,200,000 inhabitants. One of the most extensive plants in Germany for removing iron from ground water is that at Erlenstegen for removing the iron from the ground water supply of Nuremberg. Munich obtains its water supply chiefly from spring and infiltration galleries constructed in the layers of sand and gravel in the western slopes of the Alps. Those galleries of concrete in some parts intercept the flow of ground waters. The water so collected is conducted to the city, which in 1911 consumed daily 57 gallons for each of its 571,000 inhabitants.

Hamburg obtained its water from the river Elbe and prior to the epidemic of Asiatic cholera in 1892, that water was unfiltered. In 1893 a municipal filtering plant was installed. Later a deferrization plant was also installed there. In 1913 Hamburg daily consumed 37 gallons for each of its 977,000 inhabitants. Double filtration is employed in Altona, Bremen and Schiedam.

Vienna obtains its supply of pure water through masonry-arched aqueducts, whose interior measurements are 0.84 by 0.93 meters from springs 913 feet and 1,196 feet, respectively, above sea-level and about 400 feet to 600 feet above distributing reservoirs in the city and from ground waters in the Schneeberg region 59 miles distant in the Alps, and from other springs and the Salza River, 114 miles distant. These are gravity systems, but in the city some pumping is necessary to fill the highest service reservoirs about 550 feet above sea-level. Since its introduction and the use of sterilizing agencies typhoid has nearly disappeared. Such Alpine sources, however, are quite devoid of pathogenic bacteria. In 1914 Vienna consumed 25 gallons per day for each of its 2,066,000 inhabitants.

Rome for centuries has obtained its water supply from the Tiber and springs along its left bank and later from such Apennine sources as the Appia, the Anio Vetus, Aqua Tepula and Lacus Alsietinus and from such springs as fed the Aqua Virgo, Aqua Marcia and Aqua Claudia and from the Rivus Herculaneus. The Aqua Trajana drew its waters from springs west of Lacus Sabatinus, whose polluted waters contaminated those of the aqueduct. Aqua Alexandrina drew its waters from springs that now supply Aqua Felice. The Aqua Marcia drew its waters from numberless springs, discovered by Marcus in 145 B.C. Most of the longer aqueducts were partially subterranean and some have entirely disappeared.

From 'The Aqueducts of Ancient Rome,' by John Henry Parker, the following important facts are derived as to the water supply of Rome, one of the problems for engineers to solve.

In the time of Nerva and Trajan from 94 to 107 A.D. Sextus Julius Frontinus was water commissioner of Rome and has left a report of some of its remarkable works. At that time he says nine aqueducts entered the city, namely, (i) Aqua Appia; (ii) Aqua Vetus; (iii) Aqua Marcia; (iv) Aqua Tepula; (v) Aqua Julia; (vi) Aqua Virgo; (vii) Aqua Alsietina; (viii) Aqua Claudia, and (ix) Aqua Novus. Seven were constructed later, namely, (x) Aqua Sabatina, A.D. 110; (xi) Aqua Trajana, A.D. 120; (xii) Aqua Aurelia, A.D. 185; (xiii) Aqua Severiana, A.D. 190; (xiv) Aqua Antoniniana, A.D. 215; (xv) Aqua Alexandrina, A.D. 225; (xvi) Aqua Argentiana, A.D. 300. In the Middle Ages two more were constructed, namely, (xvii) Aqua Carbra and Marrana, A.D. 1124, and (xviii) Aqua Felice. Some of these are also known by other names, namely (vii) Aqua Claudia as Cerulea; (ix) Aqua Novus as Attica; (xvii) Aqua Carbra and Marrana as Herculea; (i) Aqua Appia as Augustea; (ix) Aqua Claudia, or (x) Sabbatina as Ciminia and Cloaca Maxima as Damnata, which forms the lake of Curtius.

The Roman engineers so constructed conduits that they had frequent openings and angular turns with possible intercepting bars or baffles to check the flow of matter in suspension and thereby rid the water of some of its impurities, which, except those brought by the Paola (or ancient Sabatina) aqueduct, were few on account of its Apennine and other sources. There were many *piscinæ* or *castella aquæ* or reservoirs, where sedimentation and some filtration took place and visible foreign matter was removed. The Romans had many *thermæ* and fully understood the importance of pure water. The *Piscina Mirabilis* at Baia is well preserved, which place the author visited in 1905.

William P. Mason in his 'Water Supply' quotes a passage from Pliny's 'Natural History' which has been translated as follows: "Among the blessings conferred on the city by the bounty of the gods is the water of the Marcia, the cleanest of all the waters in the world, distinguished for coolness and salubrity." The Romans had such baths as those of Caracalla, Diocletian and Titus where they repaired for hot and cold baths, for hygienic exercises and where they engaged in the discussion of political, philosophical and other topics. They gave much consideration to their water supply. They built aqueducts to bring water from distant mountain sources, that have been the admiration of later ages. Modern Rome has a daily supply of 65,000,000 gallons obtained largely through the Vergine, Felice, Paolo and Pia (or ancient Marcia) aqueducts and from springs. The Vergine aqueduct is 11.8 miles long and daily conveys its 14.08 million gallons of spring water 79 feet above sea-level, discharging it in Rome 66 feet above sea level. The Felice aqueduct daily conveys its 4.4 million gallons of spring water, the intake being 217 feet above sea-level, 22 miles from Rome, the aqueduct running over arches 6.25 miles and

the remainder of the distance underground and delivers its waters 202 feet above sea-level. The Paolo aqueduct daily draws 17.6 million gallons from Lake Bracciano, 538 feet above sea-level and from springs in Manziano, Bracciano and Ficarello 32.33 miles from Rome and delivers its supply partly in Rome at an elevation of 246 feet above sea-level to supply the fountains of the Piazza Saint Pietro and partly to supply the town of Leonina. The Pia or Marcia aqueduct, 33 miles long, is fed by a number of springs near Subiaco 1,000 feet above sea-level. It follows that valley of the Anio to Tivoli and conveys 27 or more million gallons daily into the ancient Varo reservoir, having a capacity of 214,000 gallons and being 578 feet above sea-level, and thence to Rome. The water is conducted through three cast-iron pipes 24 inches in diameter into different parts of Rome. It also derives some of its waters from springs nearer Rome than the above sources. Its numerous fountains are supplied with waters conducted through some of the old aqueducts, whose names have undergone some change, as above stated, in consequence of the discovery of additional sources by various emperors and the connection thereof with the old aqueducts. The poorer qualities of water were used for fountains, public baths and other non-potable municipal purposes.

In 1900 some of the waters in their natural state carried too large a number of bacteria for safety, but since that time it is possible that some of the recent processes of purification may have been utilized. The ozone process is adequate to rid such waters of their pathogenic germs. In 1911 modern Rome daily consumed 120 gallons of water for each of its 542,000 inhabitants. During the Roman era it consumed approximately 32,000,000 gallons daily. The remains of Roman aqueducts still exist in Asia Minor, Algeria, France, Spain and elsewhere, showing that the Romans took great pains and went to great expense to provide their cities with the best natural waters obtainable. Some of the aqueducts were of superb construction, as were the Pont-du-Gard, the aqueduct at Segovia and the Aqua Claudia, extending along the Roman Campagna.

Naples obtains its supply in part from ground waters collected in filtration galleries 2,000 feet or more in length, constructed in a stratum of gravel 30 feet below the surface, wherein are daily collected 38,000,000 gallons. Five parallel tunnels have been formed in the old quarries of Capodimonte for impounding such waters. The Apulian aqueduct in the southeastern part of Italy is of masonry construction for 151 miles. Its main trunk line and lateral branches altogether are 1,690 miles in length. Its waters supply 152 service reservoirs and nearly 2,000,000 of people. Italy has both the Alps and the Apennines to intercept the vapor-laden clouds, whose waters supply its many streams and its dense population.

Paris has two general systems for supplying water under different pressures, namely, (1) a high-pressure system for its domestic or potable supply, (2) a low-pressure system for industrial, street-cleaning and general municipal, other than potable purposes.

1. Paris obtains its high-pressure supply for

domestic purposes from four sources, namely, (a) from the springs that are tributaries of the Vanne River 108 miles distant, conducted through the Vanne aqueduct into the two-story reservoir at Montrouge 262 feet above sea-level; (b) from springs that are tributaries to the Loing and Lunain rivers, whose waters are conducted through the Loing and Lunain aqueduct into the Monsouris reservoir (that supply and the Syphon aqueduct are described and illustrated in 'La Derivation du Sources du Loing et du Lunnain' par Bechmann et Babinet, published at Paris 1905); (c) from the Dhuis springs 82 miles distant, flowing from the east through the Dhuis aqueduct into reservoirs at Menilmontant having an elevation of 354 feet above the sea, and (d) an additional supply for domestic purposes from the springs of the Avre, 63 miles west of the city, flowing through an aqueduct into Saint Cloud reservoir. During the World War the Dhuis supply was cut off and the demands on the other sources were greatly increased.

2. Paris obtains its low-pressure supply for industrial and general municipal, other than potable, purposes from the Seine pumped at Ivry and at other places on that river and from the Marne at Saint Maur and from the Ourcq Canal and from artesian wells, and water is also obtained through the Arcueil aqueduct from Rungis.

The works at Saint Maur include sedimentation basins, sand filters, ozone sterilizers and a bacteriological laboratory. In pre-war 1914 conditions, the raw Marne water carried 12,000 *B. coli* per cubic centimeter. After passing the sand filters these were reduced to 300, which disappeared as the water passed through the ozone sterilizers. An additional supply for domestic purposes was found necessary and river water was thoroughly treated, purified and used. The entire supply for domestic and potable purposes before the World War was about 40 gallons per day for each resident of the city. The supply for other municipal purposes is three times per capita the amount used for domestic and potable purposes. Since the World War, the Marne and other rivers in northeastern France, in which are countless human remains, have carried a great increase of pathogenic and other bacteria. The water supply of the entire war zone has been polluted.

The ozone treatment was so successful at Saint Maur that it was adopted by the municipality of Paris to purify the water of the Seine, taken to supplement its general municipal water supply. Miquel in 1896 found 300 bacteria per cubic centimeter in the Seine above Paris and Clichy found 200,000 bacteria per cubic centimeter in the Seine below Paris.

The Belleville reservoir has two stories. The upper receives water from the Dhuis aqueduct and the lower from the river. The Montrouge receives water from the Vanne aqueduct into its upper stories and water from the river into its lower story. The Montmartre reservoir receives spring water into its three upper stories and river water into its lower story.

The water supply of the city of London is obtained from the yield of the watersheds of the Thames, the Lea and the New River, comprising an area of 620 square miles and from

springs and many wells in those watersheds and in the chalk deposits of Kent. Formerly eight or more companies pumped the water from the Thames, the Lea and the New rivers and from springs and wells into 65 or more reservoirs. Some of the principal ones were included in the works of the New River Company, the East London Waterworks Company, The Southwark and Vauxhall Water Company, the Company of the West Middlesex Works, the Company of Proprietors of Lambeth Waterworks, The Governor and Company of Chelsea Waterworks, The Grand Junction Waterworks Company, The Company and Proprietors of the Kent Waterworks and The Staines Reservoirs Joint Committee, supplying Kempton Park reservoir. In the literature on the subject these legal titles are omitted and the popular names of the particular companies are used.

From the Thames above its tidal flow and above Teddington lock, 185½ million gallons were available, from the Lea all its flow except 5,400,000 gallons left for navigation and from the New River 22½ million gallons were pumped. Upward of 33,000,000 gallons were obtained from springs and wells. In 1900 London consumed 226,000,000 gallons of water daily, which was distributed through 3,500 miles of pipes. The Thames, the Lea and the New rivers 20 years ago were subject to pollution from the inflowing surface waters, and their filtered waters as well as waters obtained from wells contained from 15 to 100 bacteria per cubic centimeter. In 1902 an act was passed creating the Metropolitan Water Board. It was authorized to acquire the properties of the eight or more water companies above named and to enforce rigid regulations for the protection from pollution of the sources of London's water supply. Royal commissions investigated and reported on the purity of the supply, and out of the 294 experiments made by Dr. A. C. Houston in 1907-08, not a *bacillus typhosus* was isolated, though millions of bacteria were discovered, the Lea being most heavily laden with them.

The Metropolitan Water Board was created by the act of 1907. That board took over the properties and facilities of the Metropolitan Water Board. The New Works Act of 1911, authorized the Metropolitan Water Board to construct large storage reservoirs at Staines, Laleham and Shepperton. New service reservoirs were constructed on Horseendon Hill, Greenford and on Barn Hill.

In January 1913 the Metropolitan Water Board, through the various intakes, drew daily from the Thames 132,859,184 gallons and from the Lea 55,300,700 gallons and from springs and wells 36,712,390 gallons and from ponds 203,600 gallons. The aggregate of that supply was 225,075,874 gallons, which was at the rate of 33.44 gallons per person. New reservoirs are being constructed to provide additional waters and the daily consumption in 1918 was reported at 39 gallons per capita for a total population of 6,783,897.

Parliament has passed several acts for the conservancy of the waters of the Thames, Lea, New and other rivers and has empowered boards and commissions to take such action as may be necessary to protect the waters of said rivers from pollution by regulating the uses

of their watersheds and otherwise by enforcing sanitary ordinances on the part of cities, towns and villages.

Most thorough and exhaustive investigations have been made in both London and Paris to ascertain the quality and the bacteria in the raw waters, which are the sources of supply for those cities and every precaution is taken to rid all such potable waters of their pathogenic species.

The official reports of Dr. A. C. Houston, director of the Metropolitan Water Board, over a series of years and of his skilled staff of experts at London are exhaustive. They show all phases of the water supply of London, including its sources, amount, quality, bacteriological and chemical tests, the processes for its purification, the results obtained, its distribution and all other conditions incidental thereto. In his official report for 1913 Dr. Houston said that "about eighty percent of the London Water Supply is derived from rivers polluted directly or indirectly with sewage, . . . that the three factors of sedimentation, devitalization and equalization are indeed of supreme importance in connection with the storage of impure water antecedent to its filtration. . . . The practice of occasionally 'dragging' or 'raking' the surface of the filter beds to increase the yield of water or to prolong their working periods should be discontinued altogether, or only resorted to under quite exceptional circumstances. . . . Over eight years' work on the London water question has convinced me that to a progressively increasing extent the Water Board are securing the reasonable if not absolute 'safety' of the Metropolitan Water Supply. This opinion will carry the more weight since I have been, and still remain, a somewhat merciless critic of any imperfections in processes of water purification. . . . As a counsel of perfection, I still feel bound to advocate the choice of an initially pure source of water supply; but my own results and experiments do seem to indicate clearly that the evil effects even of an impure source can be largely, if not entirely, annulled by adequate storage and efficient filtration. . . . In conclusion, my opinion is that the 'quality policy' of the Metropolitan Water Board should be directed towards securing an 'epidemiologically sterile' water (i.e., a water containing none of the microbes associated with waterborne epidemic disease) antecedent to filtration by means of storage (sedimentation, devitalization and equalization) aided, if need be, by the occasional employment of supplementary processes of water purification."

For the years 1906-13 the average number of microbes per cubic centimeter as reported by Dr. Houston in raw Thames water were 4,894, in the raw Lea water were 13,293 and in the raw New River water were 2,081.

He also reported that by the processes of subsidence and filtrations the number in raw Thames water was reduced from 5,250 to 16.1 per cubic centimeter, in raw Lea water from 9,263 to 30.9 per cubic centimeter and in the raw New River water from 2,172 to 14.1 per cubic centimeter. In all these cases the reduction was upward of 99 per cent. The filtered waters from Kent had but 7 microbes per cubic centimeter and there were in the Chelsea filtered supply only 7.3 microbes per cubic centimeter.

Dr. Houston in his report for 1913 also stated that "The striking fact has been shown in my last reports that London is not really drinking merely filtered raw river water but raw river water, which by storage processes has been purified bacteriologically antecedent to filtration to a reasonable extent. . . . When it is remembered 90.5 per cent of the samples of raw Thames contain typical *B. coli* in each cubic centimetre and that 84.8 per cent of the samples of raw Lea water also contains typical *B. coli* in each cubic centimetre, the transformation which the river water has undergone previous to filtration becomes strikingly apparent." Dr. Houston strongly advises storage preliminary to filtration and storage he says means sedimentation, devitalisation and equalization. Nearly the entire supply for London is stored antecedent to filtration. Dr. Houston also stated that "99.9 per cent of the typhoid bacilli could not be recovered after one week."

Down to 1913 storage and sand filters had efficiently purified the waters used for potable purposes in London. Dr. Houston, however, in his report for the year recommended supplementary processes of purification. Since 1917 the entire water supply of London has been treated with chlorine. Before filtration, it receives a dose of calcium hypochlorite. Slow-sand filters are now used at the various works.

The twelfth annual report of Director Houston for the year 1917-18, contains an exhaustive report of chlorination, super-chlorination and de-chlorination experiments with 224 microphotographs.

The thirteenth annual report of the director for the year ending 31 March 1919, discusses the scientific results of the chlorination of the Thames and New River raw river waters and chlorination in relation to filtration and the condition of the raw and filtered waters. On 31 March 1919, the equipment of the London water supply under the Metropolitan Water Board comprised 48 storage reservoirs with a total capacity of 1,981,500,000 gallons and 86 service reservoirs for filtered water with a capacity of 310,900,000 gallons and its 172 filter beds had a total area of 170.7 acres.

Liverpool obtains its supply from wells, from eight impounding reservoirs in the watershed, Ravington having a capacity of 4.1 billion gallons and from the impounding reservoir, the largest in Europe, 825 feet above sea-level, formed by a dam 1,172 feet long and 84 feet high across the valley of the Vyrnwy River, formerly a glacial lake in north Wales, having a capacity of 12 1/7 billion gallons. The impounded waters from the Ravington reservoirs are delivered through a 44-inch cast-iron pipe 24 1/2 miles long to Liverpool and from Vyrnwy reservoir through a 39-inch cast-iron pipe 63 miles long and a tunnel 4 miles long to Prescott reservoir at Liverpool. The water is filtered through sand filters and otherwise treated. Upward of 38,000,000 gallons are consumed daily in Liverpool, which is at the rate of 40 gallons per capita per day. An additional reservoir has been constructed near Malpas and a high-level tank has been built at Woolton Hill.

Manchester obtains its water supply from the elevated Longdendale watershed with seven or more impounding reservoirs along the

Etherow River and from Lake Thirlmere 2 1/4 miles long and 533 above sea-level in the north-western part of England. The outlet of the lake is closed by a masonry structure 857 feet long and 104 1/2 feet high from the lowest part of the gorge outlet. That enlarges the lake to three and one-fourth miles in length and gives it a capacity of eight and one-seventh billion gallons. The aqueduct leading to the city is 95 miles long and carries 50,000,000 gallons per day. The storage reservoirs of Manchester have a capacity of upward of 41,000,000 gallons. Its daily consumption is 40 gallons per capita and aggregates 50,000,000 gallons. A third conduit has recently been constructed from the lake to the city.

Birmingham, England, formerly obtained its water supply from five local streams and eight wells. From these the water was pumped into six service reservoirs at different elevations and into a stand-pipe. All such waters were filtered. In 1900 there were 12 sand filter beds with a total area of eight and one-fourth acres. In 1892 Parliament authorized Birmingham to draw an additional supply from Elan and Claerwen rivers in Wales. It constructed six long reservoirs by building masonry dams across the narrow valleys of those rivers, one of which dams was 600 feet long and some were more than 100 feet in height above the bed of the gorges so closed. They had a combined capacity of 18,000,000,000 gallons. There were also constructed 30 filter beds for the filtration of all such waters. This improvement contemplated a supply of 75,000,000 gallons a day for service in addition to 27,000,000 gallons to compensate for losses to riparian operators along the Wye.

The water flows by gravity through the Elan aqueduct 73.3 miles to Birmingham. From the elevated sources to the high service reservoirs in Birmingham there is a fall of 170 feet.

In 1913 there were consumed 27,471,991 gallons daily, which was an average of 32.24 gallons for each resident.

Glasgow obtains its water supply from Brock Burn six miles from the city through its Gorbals works into four impounding reservoirs, having a combined capacity of 1,000,000,000 gallons or more and also from Loch Katrine 364 feet above sea-level, having a storage capacity of five and two-thirds billion gallons. The water was conducted by gravity through aqueducts and tunnels 27 miles to Mugdock and Cullinstown reservoirs, having a combined capacity of one and one-fifth billion gallons. Reservoirs have been constructed in the valley of the Clyde to compensate for waters drawn by the city. In 1895 it was decided to connect by the tunnel Loch Arklet 455 feet above sea-level with Loch Katrine and raise the outlet of the latter five feet and thereby secure a storage capacity of 2.05 billion gallons in the two lochs. An additional reservoir with a capacity of 694,000,000 gallons has been constructed. In 1913-14 Glasgow daily consumed 75 gallons per capita or an aggregate of 85,000,000 gallons.

Edinburgh obtains its water supply from Esk, the water of Leith and from the Pentlands, the Moorfoot and from Talla Water reservoir. Talla Water is an affluent of the River Tweed.

In 1913 the daily consumption of water in

**WATER SUPPLY**

**The great waterwheel at Hama, Syria, used for pumping the water out of the Orontes River**

Edinburgh and Leith was 56 gallons per capita.

The Derwent Valley Water Supply under an Act of Parliament, is distributed to Derby, Leicester, Nottingham and Sheffield, the expense of which is borne by said several corporations in proportion to their several allotments or percentages of water consumed, all drawing from the same source, made available by their joint effort. That plan might be carried out in other countries where a common supply may be available for several municipalities.

In 1907 the Earl of Cromer reported that the Assouan reservoir would supply one-fourth of all the water needed in Egypt. That water flowed from the upper Nile 1,800 miles to reach Egypt. The evaporation in those torrid and tropical regions was 103,000,000 cubic meters out of 2,300,000,000 cubic meters of supply and the loss by absorption and filling the Nile trough was 260,000,000 cubic meters, and the consumption in middle Egypt was 850,000,000 cubic meters, which left only 1,087,000,000 cubic meters for use in Lower Egypt at Cairo. That statement shows the great losses of river or canal waters due to evaporation and percolation or absorption. Under all conditions they are factors to be considered in determining the amount of water supply for a community. Long before the Assouan reservoir was constructed, Jacob had dug a well near the site of Cairo and still earlier the Fayum depression was embanked and Lake Moeris was formed, around whose shores were settlements from the Neolithic age down through many centuries.

In 1914 Cairo used for all purposes an amount equivalent to 25 gallons for each of its 700,000 residents. Its water is clarified by passing it through rapid sand filters. Alexandria has a similar plant of 12,000,000 gallons daily capacity, where sulphate of aluminum is used as a coagulant.

The importance of wholesale water supplies to communities cannot be too emphatically stated, when we recall the ravages of diseases due to the contaminated water supplies in India. Prior to the British sovereignty of that Peninsula nearly all well, river and surface waters were unfit for potable purposes. Conditions there were appalling. The waters of the Indus, the sacred Ganges, the Brahmaputra and of all other rivers were laden with putrescent matter and some with decomposing human remains. Even the wells were contaminated and the thousands of reservoirs and tanks were used as bathing pools by thousands of dust begrimed and filthy pilgrims in their annual tours of parts of India. They were ignorant of the laws of health and oblivious of all hygienic and sanitary regulations. That was the commencement of water purification in central India. There are now many sand filtration plants in India.

The Hindus were enjoined to drink the water of the Ganges, as a sacred duty. Cholera and other deadly epidemics depopulated whole districts. When the British officials began to exercise authority, they undertook to remedy conditions wherever they were able so to do, but the superstition and prejudices of the

natives were such under their Indian cults, that progress was slow.

In 1893, the Balram Dass Waterworks were constructed at Raipur in the central provinces. Those consisted of an infiltration gallery 100 feet from and paralleling the Karou River whose level was raised at that point six feet by a dam and its waters percolated the intervening sand layers and weeped through holes into the gallery. Thence they were pumped up through a conduit of masonry and cut through the rock into tanks for distribution. The supply was six and one-half gallons a day per capita. Consult Vol. 143 of Proceedings of Institution of Civil Engineers, pp. 262 et seq., London.

In 1901 the British favored the construction of works for the extension of irrigation from 47,000,000 to 53,500,000 acres.

In 1905 to 1912, they aided in the construction of the Punjab Triple Canal system, which had an excellent effect upon the quality of flowing water for the thousands dependent thereon for drinking purposes. Consult Vol. 201 of Proceedings of Institution of Civil Engineers, pp. 24 et seq.

Prior thereto the inhabitants in that part of India obtained their supply from polluted ponds and other unwholesome sources. The irrigation works of India are extensive and have done something to relieve the deplorable conditions of the millions untutored in hygienic science. All such Indian watercourses as the extensive Punjab Triple Canal system, the Bengal system, the Madras canals, the Ganges and the Indus systems supplied waters for irrigation and formerly to some extent waters for navigation. In a land of such intense heat and extensive barren areas, most of such watercourses supplied all the water obtainable for potable as well as for all other purposes. Slowly the people of the peninsula are beginning to understand some of the causes of the cholera, typhoid and other fatal epidemics that have swept over India from the Buddhist period, commencing 520 B.C. down to recent years. Who can estimate India's mortality directly attributable to its pathogenic-bacteria-polluted water supplies? What costly sacrifices the race has made to its ignorance of and failure to observe the laws of health! Polluted waters are disease producers, as unailing as the forces of gravity on falling bodies. India with its dense population and appalling pestilential epidemics is an inimitable example of the dreadful results of the use of unwholesome waters for domestic and potable purposes. Modern modification processes have been installed in its principal cities and ports, so the danger of infection in those towns is constantly lessening. In 1914 Bombay consumed 27 gallons, and Calcutta 62 gallons daily per capita. In the waterworks of Calcutta alumino-ferric is used as a purifier, which is an impure sulphate of aluminum. That is generally used as a coagulant elsewhere in India. Mechanical filters at Betmangula, India, reduced the bacteria in Palar River water from 4,350 to 13 per cubic centimeter. The training of some of the river courses, such as the Rangoon, has resulted in the improvement of their waters for domestic uses. Gradually the people are beginning to realize the importance

of preserving their streams and watercourses, including reservoirs, tanks, etc., from pollution.

China and Japan in the past centuries were hardly less oblivious of hygienic and sanitary laws, though less frequently swept by epidemics attributable to waterborne diseases. The Chinese obtain their water supplies from wells, springs and their rivers. There appears to be some natural purification of their waters and less human pollution of them. They are accustomed to boil their drinking water and that disposes of many bacteria.

Japan is abundantly supplied with lakes, rivers and waterfalls and is fast advancing in sanitary science. It has already commenced to adopt some western methods for the purification of its water supplies. George A. Johnson of the United State Geological Survey says: That "the water purification works at Osaka, Japan, having a daily capacity of 25,000,000 gallons, include open sedimentation basins and also sand filters." One was completed in 1903. Bacteria in Yodo River water were reduced from 200 to 25 per cubic centimeter. There is also a slow sand filtration plant at Yokohama, whose water supply is taken from the Sagami-gawa. Water purification is also effected to some extent in Tokio, where were consumed in 1914, daily 32 gallons by each of its 1,500,000 residents. It takes its water from the river Tama into the city reservoir at Yodobashi, located high enough to afford nearly 100 feet pressure. There potash alum was used as a purifier. At Kyoto there is a large rapid sand filtration plant.

Melbourne in Australia derives its water supply from the Yan Yean system, consisting of Silver Creek, Wallaby Creek and the Plenty watershed yielding 33,000,000 gallons daily and from the Maroondah or Watts River system yielding 25,000,000 gallons daily, and from Survey Hills yielding 9,000,000 gallons daily. There are six service reservoirs with a combined capacity of 45,000,000 gallons. The daily supply in 1905 was 63 gallons per capita. In 1899 the waters in the service reservoirs and mains carried from 146 to 398 bacteria per cubic centimeter. *B. coli* were found in some reservoirs fed from drainage areas, where there was no sewage and other micro-organisms were also found. That shows how prevalent they may be when least expected. The presence of such bacteria is usually attributable to pollution by sewage. The obtaining of pure and wholesome water is not the least of municipal problems nor of rural communities.

In New South Wales a dozen or more narrow gorges have been dammed and their waters impounded for domestic purposes. So in all inhabited parts of the world, the problem of water supply is of first importance, and is becoming increasingly so as the population increases in density.

**Some American City Supplies.**—In addition to the municipal supplies already mentioned, the following illustrate the methods adopted in the United States for obtaining wholesome water supplies.

Boston, Mass., is in the Metropolitan Water District, which obtains its supply from lakes and rivers, whose waters are impounded in reservoirs. Cochituate Lake, Sudbury River and the south branch of the Nashua River are

its principal sources. The first of these comprises a series of ponds three and one-half miles long, and their waters flow through an aqueduct into Chestnut Hill reservoir, having a capacity of 23,000,000 gallons a day. On the Sudbury River four storage reservoirs, an aqueduct and a conduit were built. They carry 108,000,000 gallons a day, 15.9 miles to the Chestnut Hill reservoir. The waters of the south branch of the Nashua are impounded in the large Wachusett reservoir, at Clinton, having a capacity of 64,500,000 gallons in its 6.46 square miles of area. It is 12 miles from the Sudbury reservoir, into which its waters are conducted by the Wachusett aqueduct, and from one of the Sudbury reservoirs by the Western aqueduct built in 1904, to the westerly part of the metropolitan district. The daily capacity of the Wachusett aqueduct is 300,000,000 gallons. The site and shores of the Wachusett reservoir were stripped and that proved satisfactory, for algae and other plant organisms do not thrive where rock constitutes the bottom and sides of such reservoirs. The water in the reservoirs is not polluted and is remarkably free of organisms, due to the stripping of the sites and the freedom of the catchment areas from pollution, except such as are within the towns of Marlborough and South Borough. *Diatomacæ* have been found in Lake Cochituate and occasionally small numbers of harmless bacteria in the tap water.

In the Metropolitan Water District of Boston are several other corporations and the supply is metred for different uses.

New York City obtains its water supply from six different sources. Those are with their respective available daily yields: (1) The Croton watersheds with 336,000,000 gallons; (2) The Bronx and Bryan watershed with 18,000,000 gallons; (3) the Esopus watershed with 250,000,000 gallons to be augmented by the Schoharie Creek addition of 250,000,000 gallons; (4) the Long Island watersheds comprising the Ridgewood and other systems, and including Queens (in reserve) with 150,000,000 gallons; (5) the Staten Island watershed, in reserve, with 12,000,000 gallons, and (6) private water companies with 34,000,000 gallons. The foregoing amounts, except that from Schoharie Creek, soon to be added, are given in the instructive paper of Dr. Frank E. Hale, chief chemist of the Department of Water Supply, Gas and Electricity. No other modern system has involved a greater expenditure, except possibly that of London, and none is delivering a greater quantity unless it be that of Chicago. Certainly its quality is as pure and wholesome as that of any city in the world. All its catchment areas are under the supervision of sanitary inspectors and its Catskill supply is largely from lands owned and cleared by the city. Every precaution has been taken to avoid pollution of the sources, and some of which are in the foot-hills and slopes of mountains. Physical, chemical, bacterial and microscopical examinations are periodically made of the various sources.

Several modern processes of purification including liquid chlorine at several plants are in use. They comprise an aerator at the Ashokan reservoir, a coagulation plant above the Kensico

reservoir on the Catskill aqueduct, a Dunwoodie chlorination plant on the new Croton aqueduct, a chlorination plant on the Catskill supply below Kensico reservoir, following aeration, a slow sand filter plant below Oakland Lake in Queens County, whose bacterial efficiency is supplemented by liquid chlorine and several slow and several rapid sand filter plants located on various conduits of the minor sources of supply. One of the latter is at Baisley Pond. Micro-organisms which are destroyed by treatment with copper sulphate, and iron, have been found in some of the waters. The processes used have been efficient in purifying any waters that have been so infected.

and other supplies, including about 96,000,000 gallons of ground waters from Long Island.

In 1918 there were daily distributed for all purposes in all the boroughs of Greater New York approximately 600,000,000 gallons, that being a little more than the rate of 100 gallons per capita.

The waters of the Schoharie Creek or watershed are to be impounded in a reservoir at Gilboa dam, and carried in a tunnel 18 miles long under the Shandaken Mountains into the upper reaches of the Esopus Creek and thence into the Ashokan reservoir to double the present (1919) supply. When that improvement is completed there will be 500 million gallons available a day for New York city, from the Catskill and Scho-

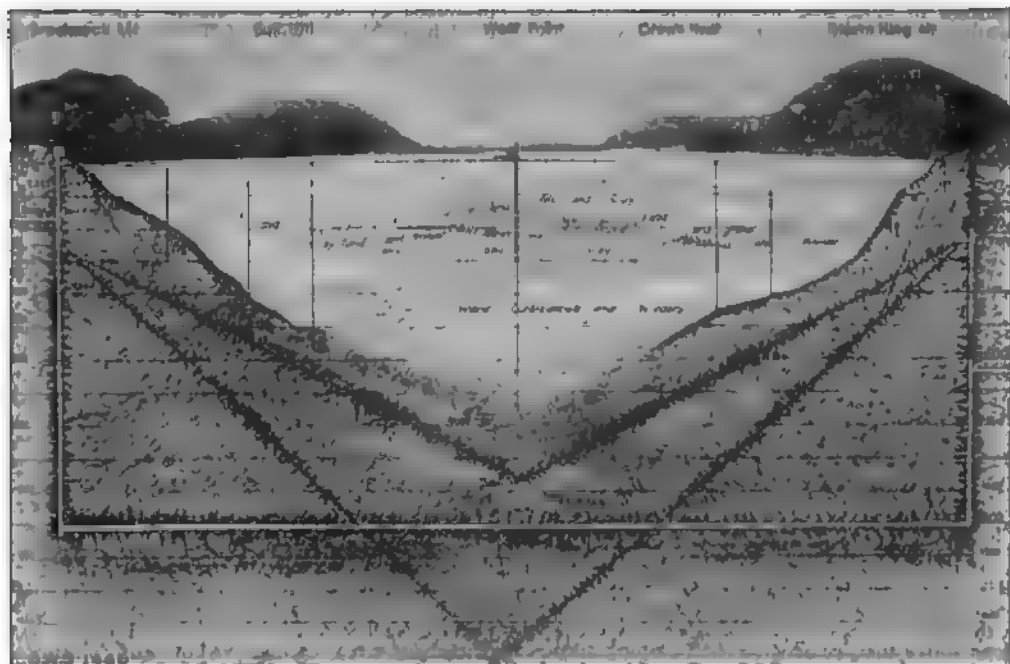

FIG. 2.

Bacteria in the waters of the several Croton and Catskill aqueducts varied from 17 to 68 per cubic centimeter, but chlorination reduced the number from 46 to 91 per cent. In 1918 storage in the Ashokan reservoir reduced *B. coli* 99.8 per cent and other bacteria 69 per cent. Several species of *Diatomacea Cyanophyceae*, *Protozoa* and *Crenothrix* have been localized in the waters of the New York supply.

The Esopus supply is from several streams, whose waters are conducted into the Ashokan reservoir 91 miles northwest of the city and thence are conducted in an aqueduct having a daily capacity of 500,000,000 gallons down the west side and under the Hudson 1,100 feet below its surface (Fig. 2) and up to the Kensico reservoir, thence to the Hill View reservoir with an elevation of 295 feet, which determines the "head" of the Catskill supply and thence in a tunnel extending down through New York City to the distributing reservoirs in the several boroughs. These receive also the Croton

and Schoharie watersheds, having an area of 571 square miles. The Ashokan reservoir has an elevation of 587 feet above tide-water and its outlet is 495.5 feet above tide-water. Its capacity is 128 billion gallons. The Gilboa reservoir will have a capacity of 20 billion gallons, and has an elevation of upwards of 1,100 feet above tide water and is 125 miles from New York City.

Albany takes its supply from the raw Hudson River water through screened intakes and passes it through two 18-inch inlets and one 36-inch inlet into a sedimentation basin. After sedimentation, it passes roughing filters into the slow sand filters where the daily rate of filtration is 3,000,000 gallons per acre. It then passes into the covered filtered water reservoirs. Its capacity is 21,000,000 gallons per day and its bacterial efficiency is 99 per cent. The usual bacterial efficiency of slow sand filters ranges from 98 to 99 per cent.

Chicago obtains its daily supply of 1,000,000,000 gallons from Lake Michigan, through nine

intake tunnels, reaching seven intake cribs two or more miles from shore.

In 1915 the Chicago Board of Experts reported that its water from Lake Michigan was turbid, polluted and unsafe for drinking purposes. The opening of the Drainage Canal in 1901 to send the flow of sewage down the Illinois River lessened the pollution of near shore lake waters, but did not wholly remedy the difficulty. City sewage still flows to a limited extent into the lake and pollution continues. The problem is a serious one for Chicago as it is for all other cities similarly situated. The intakes of other Great Lake cities, however, are not so near the effluents of their sewage and there is less direct pollution therefrom. Chlorination was tried in one of the districts in Chicago in 1912, and was attended with good results, except that during the winter months the plant was affected by the severe cold. Undoubtedly Chicago will adopt some modern process for the sterilization of its water supply.

In Milwaukee hypochlorite has been used to eliminate gas-forming bacteria from its Lake Michigan supply, but such large dosages were necessary, that the taste was affected and odors were produced. The water before treatment contained 2,590 microbes per cubic centimeter. Milwaukee's consumption in 1915 was 48,000,000 gallons a day, which was equivalent to 111 gallons per capita.

Cleveland in 1911 completed its new intake and a marked improvement followed. It installed a rapid sand filtration plant and also used calcium hypochlorite as a germicidal disinfectant. Its supply in 1912 was at the rate of 133 gallons per capita a day.

Superior, Wis., has a slow sand filtration plant comprising three units with a total capacity of 300,000 gallons a day.

Kansas City, Missouri, obtains its supply from the Missouri River at Quindaro above the inflowing polluted Kansas River. The raw Missouri River water is pumped into a reservoir of 90,000,000 gallons capacity at Quindaro where there is preliminary sedimentation. The water is thereafter treated with alum and lime. The clear water then returns to the pumping station and is treated in its passage with calcium hypochlorite and aerated. It is then pumped into Turkey Creek reservoir, where a high pressure service is maintained and thence it is let into the mains. The raw river water in 1911 contained as high as 30,000 *B. coli* per cubic centimeter and they were reduced by such treatment as stated to less than 100 per cubic centimeter, which is the standard of purity established in 1914 by the Treasury Department of the United States Government. The purification at Kansas City, Mo., whereby large colonies of pathogenic bacteria in its raw river water supply were eliminated, well illustrates how Missouri River water may be purified and made safe for potable uses.

Buffalo obtains its supply from Lake Erie and it is purified by chlorination at the intake pier in Lake Erie. The daily consumption is approximately 125,000,000 gallons.

New Orleans obtains its supply from the Mississippi River. A Sewerage and Water Board was created in 1899 and aerial cisterns were ordered closed. They were breeding places of the *stegomyia* which cause yellow fever. In 1909 a new rapid sand filtration plant was in-

stalled having a daily capacity of 40,000,000 gallons and the water was first put through sedimentation aided by sulphate of aluminum and ferrous sulphate as coagulants. In 1910 the rate was 5.99 million gallons per acre per day. New Orleans has two filter plants, namely the Carrollton Filters and the Algiers Filters. From an official report it appears that the rate of filtration through the former in 1914, was five-fold that of the latter. In 1915 the daily consumption was 20,000,000 gallons, which was at the rate of 57 gallons per capita.

Omaha, Neb., obtains its supply from the Missouri River which requires purification. Accordingly a series of basins were constructed for sedimentation of much of the suspended matter. That was accompanied by coagulation produced by the use of alum. There is also used hypochlorite without filtration. Since the installation of the foregoing processes of purification, there has been a great reduction in typhoid and other diseases produced by pathogenic bacteria.

Pittsburgh obtains its supply from the Allegheny River, which has several inflowing tributaries. One of these is the Kiskiminetas which receives waste products from oil refineries, tanneries and other plants. The water carries much colloidal matter. Its waterworks plant comprises concrete sedimentation basins, holding 120,000,000 gallons with 24 roughing filters of coarse stone and two hollow frame baffles, extending the full length of the sedimentation basins. These rid the water of much of the matter in suspension. It also comprises slow sand filters and a covered filtered water reservoir. The plant is unique and illustrates another type of construction to overcome conditions quite extraordinary. Its service reservoir is at Highland Park 367 feet above the river. It has several reservoirs for service in different parts of the city.

Los Angeles formerly obtained its supply from ground waters by means of infiltration galleries. Its daily consumption was 26,000,000 gallons. It is soon to obtain its supply from Owens Valley where the city owns a large catchment area. Long Valley and Tincmaha reservoirs are to be constructed with a combined capacity of 150,500,000 gallons. The aqueduct consists of open canal sections, masonry sections and tunnels and several intercepting reservoirs, each of many million gallons capacity which regulate the flow and develop power. It is so constructed that ground water near the surface may be pumped into it and augment its volume. It has 23 inverted siphons and serves both for water supply and power purposes and is one of the large water supply projects on the Pacific Coast.

San Diego has a municipal pressure filter of 5,000,000 gallons capacity.

San Francisco is supplied by five independent systems owned by a private corporation. The waters are drawn from artesian wells.

In June 1919, Sacramento decided to install a modern filtration and pumping plant with filter beds of 30,000,000 gallons daily capacity and is to use sulphate of aluminum as a coagulant. Its water supply is from river water, mountain sources and from wells.

In addition to those already mentioned, purification plants have been constructed at Wil-

mington, Cincinnati, Cleveland, Columbus, Toledo, Lorain, Youngstown, Louisville, Saint Louis, Des Moines, Minneapolis, Grand Rapids, Mich., Little Falls, N. J., Harrisburg and

fectured by chlorination and an electrolyser of the Allen-Moore cell, adopted by the Montreal Water and Power Company. The equipment comprises four cells, each having a capacity of

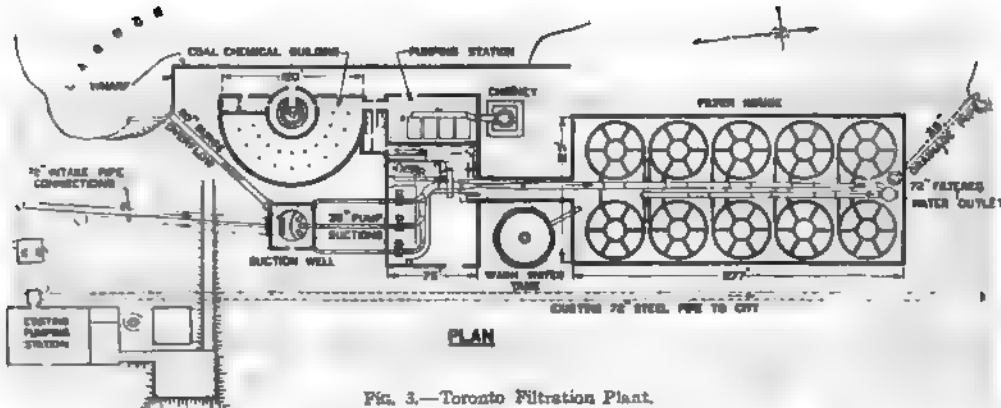

FIG. 3.—Toronto Filtration Plant.

Bethlehem, Pa., Middleboro, Mass., and at many other places in the United States and other countries.

The water supply in Canada is illustrated in the following few cases:

The Victoria aqueduct conveys waters from mountain reservoirs 37 miles away.

At the present time Winnipeg obtains waters that require softening and that involves large expense annually. It has recently decided to obtain soft water from Shoal Lake, some distance away.

Toronto obtains its supply from Lake Ontario. Its filter beds of its slow sand system have a capacity of 5,000,000 gallons per acre per day. It has recently installed drifting sand filters. These consist of 10 units, each having a capacity of 6,000,000 gallons daily. In them there is a constant vertical circulation of water through the filters, so that a part of the bed of sand is kept in suspension in the water, while some of the sand is being constantly removed and washed in transit and replaced in filters. A coagulant apparatus is attached and the coagulant goes directly to the filters. The bacteria are caught up and carried along out with the drifting sand. The process is rapid and may be expensive. The average amount of chlorine applied was 2 parts per million in 1918. In 1911 Toronto daily consumed 118,000,000 gallons.

Montreal obtains its supply from the Saint Lawrence and Ottawa rivers. The waters are conducted into the main reservoir 200 feet above the Saint Lawrence River. That reservoir has a capacity of 36,500,000 gallons. There is another high service reservoir still higher. Purification of the water supply of Montreal is ef-

fectured by chlorination and an electrolyser of the Allen-Moore cell, adopted by the Montreal Water and Power Company. The equipment comprises four cells, each having a capacity of

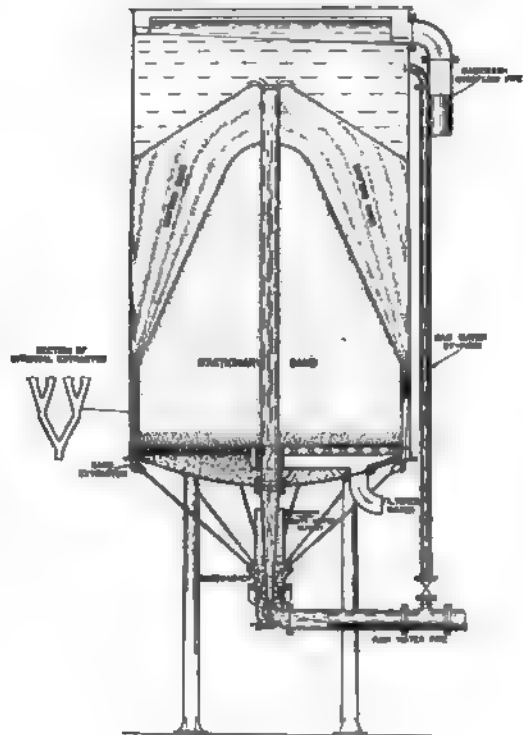

FIG. 4.—Drifting Sand Filter—Gravity Type.

The supply of water in New York City is a problem of the first importance. The city has a population of over 6,000,000 and a water supply of only 1,000,000,000 gallons per day. The water is drawn from the Croton and Catskill rivers and is treated at the Croton and Catskill water treatment plants. The water is then pumped to the city and distributed through a system of pipes. The water is treated at the Croton and Catskill water treatment plants by a process of filtration and chlorination. The water is then pumped to the city and distributed through a system of pipes. The water is treated at the Croton and Catskill water treatment plants by a process of filtration and chlorination. The water is then pumped to the city and distributed through a system of pipes.

The importance of water is obvious in connection with the progress and the health and the life of the human race. There is always the possibility that the distribution of municipal water supplies may be interrupted. In the management of water supplies, the private water supply and water main companies in New York City were the approval of the Board of Health. It may be desirable to have some reserve of other water supplies in case of an emergency. Various water supplies as they may exist in well water and in all other kinds of water. Some means of health may be provided in the regulation of approved purification processes in private dwell-

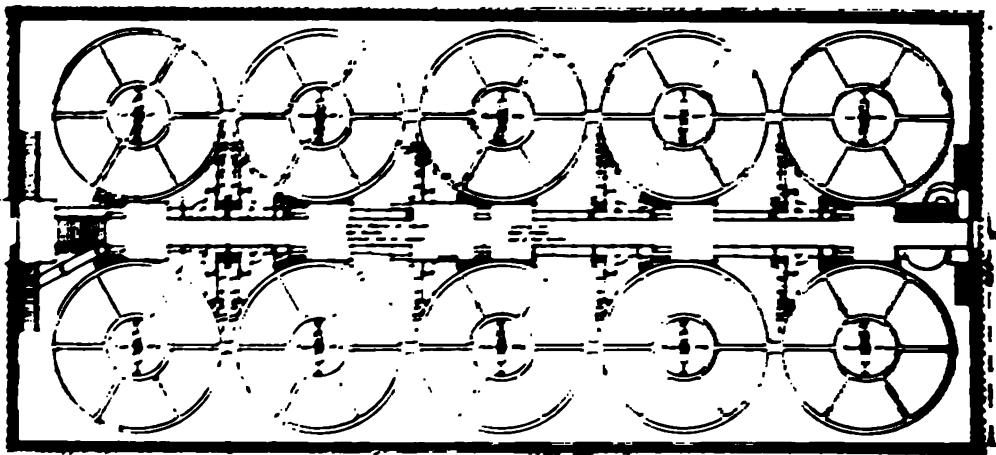

Fig. 2. General Arrangement of Pipes in Floor House

ings, hotels, hospitals, schools, offices, factories, etc. The matter is of such transcendent importance that the Treasury Department of the United States Government called together a corps of distinguished specialists in 1914, and they formulated standards of purity for water to be consumed by the public, which was being supplied by common carriers in interstate commerce.

The article is contributed in the hope that it may awaken a deeper interest in the subject than that taken by individuals and committees which have suffered most seriously from unwholesome water supplies in the past.

The foregoing will suffice to show the world-wide interest now being taken in water supply and the researches of scientists and efforts that have been made and are being put forth by all progressive communities to secure for themselves pure and wholesome water for public and other domestic purposes.

Enough has already been said to demonstrate the vital importance of water supply to communities and to individuals. In the art of the problems involved in the construction of waterworks have not been discussed for they are engineering problems and do not concern the layman. The larger and more important problems of water supply, however, have been presented at some length in the hope that readers of the *Engineering and Architecture*

will be interested in the subject.

The matter is of such transcendent importance that the Treasury Department of the United States Government called together a corps of distinguished specialists in 1914, and they formulated standards of purity for water to be consumed by the public, which was being supplied by common carriers in interstate commerce.

**WATER VALLEY**, Miss., city, one of the county-seats of Yalobusha County, on the Illinois Central Railroad, about 140 miles north by east of Jackson, the State capital, and 15 miles north of Coffeerville, the other county-seat. It was settled in 1855 by William Carr; incorporated in 1867, and chartered as a city in 1890. It is in an agricultural region, in which cotton is one of the principal products. It has considerable lumbering interests. The chief manufacturing establishments are cotton mills, railroad repair and construction shops, in which there are 500 men employed, a lumber mill, foundry and machine shops, and woodworking factory. The city owns and operates the electric-light plant and the waterworks. There are seven church denominations, the Methodist State Orphans' Home, the McIntosh Training School, and public schools for both races. There are two banks and two newspapers. The government is vested in a mayor and board of aldermen consisting of seven members elected every two years. Pop. 4,708.

**WATER WHEEL**, a machine by which the energy in falling water is utilized to perform mechanical work. Water, through its tendency to seek the lowest level—the point nearest to the centre of the earth—acts as a motive power by its weight. When the water is confined, as in a vertical pipe, this weight becomes pressure. When the water has acquired a velocity in flow its motive power is called impulse. Water wheels adapted to these various conditions may be divided into two general classes—the "vertical," consisting of the "overshot," "breast" and "undershot" wheels; and the "horizontal," which includes a great variety of turbine or reaction wheels. The impact or impulse wheels are represented in both classes. The term water wheel is correctly applicable to all forms of water motors that rotate, but in this article it will be restricted to those of the vertical class. For those belonging to the horizontal class, see TURBINE.

The overshot wheel is so called because the actuating water is fed to it from the top. It is provided with a number of buckets fixed to its periphery in such a way that as the wheel revolves the buckets on the descending side have their tops upward, and being filled with water at or near the top of the wheel, the weight of the water exerts a downward pull and the axle of the wheel being free to turn in its bearings, a rotary motion is imparted to the axle from

which it is transmitted by belts or gearing to the mechanism to be operated. The water is admitted to the wheel by various methods, such as the overfall sluice, the penstock and the guide bucket, in all of which the water is guided in a course tangential to the perimeter of the wheel. If the water is in motion, that is, has a certain velocity, when it enters the wheel buckets, it acts partly by impact, but in usual conditions the motive power of the wheel is simply the weight of water in its descending buckets, which may be roughly estimated as the cubic content in feet of two-thirds of the number of buckets, multiplied by  $62\frac{1}{2}$  pounds. To obtain the greatest efficiency, the number of buckets, ought to be as large as possible and so arranged as to hold the water as long as practicable. The buckets vary in form, but the greatest effect is obtained from curved buckets, the "radial" giving only about 75 per cent of the power obtainable by the use of "elbow" buckets. Overshot wheels may be constructed of wood or iron in any size. The earlier forms were massive structures built of wood; the modern wheels are generally built of iron and are practically limited by construction problems to falls less than 60 feet in height. The average sizes range from 8 to 40 feet in diameter.

In the breast wheel the water is received by the buckets on a level with or but slightly above the axle of the wheel. It is most effectively employed in connection with falls ranging from 5 to 20 feet, and where the flow ranges from 5 to 90 cubic feet per second. The buckets are generally held in a curb, and, not being required to hold water, are set radially. Their number is made as large as possible, and they are set at such an angle that they leave the water vertically so as not to carry up water from the tailrace. The breast wheel is more effective than the overshot where the fall is low, since it can be made of nearly double the diameter and affords an increased facility for the reception and discharge of the water by the buckets, besides gaining some power from impulse.

The undershot wheel receives the water below its horizontal centre line. Instead of buckets it is equipped with a series of paddles or vanes fixed to the periphery in such a way that the flowing water passing under the wheel pushes against the paddles, causing rotation. It is usually set in a curb with a minimum amount of clearance for the escape of the water. The most effective curbs are concentric to the wheel, those set straight or tangential allowing too much waste. The paddles are set radially and inclined upward in order to be readily emptied of water upon the return side.

For falls not exceeding six feet, the most effective wheel is the Poncelet. In it the water acts in a manner very similar to its action in a turbine, and although not quite as efficient as turbines working under normal conditions, it is superior when working under a reduced water supply. The buckets are curved, and the water flowing along their concave sides presses upon them without impact and with greater effect than that of water impinging at right angles against buckets with plane surfaces. The effect of the wheels increases with the depth of the water, and the velocity of rotation is equal to about one-half the velocity of the flowing water. The simplest form of the "impact" wheel con-

sists of a series of rectangular buckets fixed upon a wheel at an angle varying from 50 to 70 degrees to the horizontal. The water is conducted to it through a pyramidal flume set at an angle varying from 20 to 40 degrees, so that it strikes the blades nearly at right angles. The normal effect is about 5 per cent of the total mechanical power of the flow, but this may be increased somewhat by increasing the length of the paddles, so that the water exerts a combined impinging and pressing force.

In another form, known as the "impulse" wheel, a series of cup-shaped buckets attached to the periphery of the wheel are acted upon by a jet of water conducted by a pipe and delivered through a nozzle tangentially against the cups. More power is obtained by increasing the number of nozzles to two, or even four. Of this form the most notable are those of the Pelton type, which are extensively employed to work air compressors in mining operations. At first limited in usefulness to the locality of the power, the development of electric power transmission brought them into a greatly enlarged field of service. Such wheels are now operating under heads up to nearly 2,000 feet. A Pelton wheel in the service of the South California Edison Company, working under 1,900 feet head at 430 revolutions per minute, develops 1,600 horse power. This wheel has been running continuously since 17 March 1903. At a plant recently erected in Europe, a jet of water one and one-half inches in diameter under a head of 5,250 feet develops 3,000 horse power. The Rio Janeiro Traction, Light and Power Company operates a Pelton wheel with four nozzles under 900 feet of head. The power developed is equivalent to 20,000 horse power.

The efficiency of the turbine being so much greater than that of any type of vertical water wheel they are universally preferred except in the smallest water power developments. This statement, however, does not apply to the Pelton wheel whose efficiency is equal to the turbine, and is available where the head is too great for economical use in turbines. The largest vertical water wheel ever built in America was the Burden wheel, located on the bank of Wyanant's Kill, which enters the Hudson River near Troy, N. Y. This wheel was of tension construction, the 264 spokes being one and one-half inch rods bolted to rosettes on the 12 inch shaft. Its diameter was 60 feet, and its face width was 20 feet. The water was brought to the wheel through a steel penstock which crossed the wheel transversely at its summit. Four gates at intervals in this penstock were in the constant charge of the wheelman who opened or closed them so as to keep the supply such that it would turn the wheel at a constant speed of two and one-half revolutions per minute. On the outer sides of the rim were circular cogged racks which engaged with pinions seven feet in diameter and nine inches face keyed to the shaft, which projected 31 feet into the mill. This wheel was in constant operation 45 years, much of the time running night and day for long periods. It was abandoned in 1898 as of insufficient power for the needs of the business, but remained intact for 15 years thereafter before it began to fall into decay. The largest water wheel in the world is that which supplies the ancient city of Hama with water for drinking and irrigation from the river Orontes—

about 120 miles north of Damascus. This wheel is of the undershot type, 70 feet in diameter and of comparatively narrow face. It is built of wood upon an iron axle.

**Bibliography.**—Good descriptions of water wheels are scattered through the various engineering periodicals. Especially valuable data may be obtained from 'Transactions of the International Engineering Congress' (San Francisco 1916). See also **TURBINE**; **WATER POWER**; **WATER MOTOR**.

**WATER AND WHITE ALDERS.** See **CLETHRA**.

**WATER WORSHIP**, a feature of nature worship, and one of the primitive superstitions of mankind. Water was not worshipped as an element, but in its various forms of well and spring, river and ocean. Every spring and river was supposed to have an animating deity, who could be propitiated or offended, and the worship of these divinities was a prominent part of Greek and Roman cult, especially in the rural districts.

**WATERBORO**, wá'tér-bür-ō, Me., town in York County, on the Portland and Rochester Railroad, about 25 miles southwest of Portland. It contains the villages of Waterboro, East Waterboro, South Waterboro, North Waterboro, Waterboro Centre and Ossippee Mills. It was settled in 1787, and in 1789 was incorporated. The town has flour and lumber mills, an apiary for breeding bees and considerable dairy interests. Pop. 997.

**WATERBURY**, a city of Connecticut, in New Haven County, the fourth in population in the State, and one of the most important manufacturing centres in New England. It is situated on both sides of the Naugatuck River, 21 miles above its junction with the Housatonic, 22 miles northwest of New Haven and 32 southwest of Hartford. In January 1902, by an amendment to the charter, the city became coterminous with the town, so that it now covers an area seven or eight miles square. Its physical features are greatly diversified. Its streams and wet lands probably suggested its name, given to the town at the time of its incorporation. Its earliest designation, "Matetacoke" (shortened to Mattatuck), means a place or land without trees, and had reference probably to the primæval meadows on the Naugatuck.

**History.**—The first attempt at a settlement was made in 1674, by men of Farmington, on the high land west of the river, known ever since as the Town Plot. The breaking out of King Philip's War led to the abandonment of this site and the planters, when they returned, settled on the east side of the river, nearer to Farmington, calling the place the Town Spot. The settlement was formed under the order of the General Court, upon the payment of about £2,500. The men numbered 31, and for 26 years no outsider was admitted as a proprietor. Mattatuck was incorporated as a town (of Hartford County), with a change of the name to Waterbury, in 1686, occupying then a territory about eight miles wide and 18 miles from north to south.

For more than a century its growth was slow. In addition to the natural disadvantages of the situation, there were such disasters as the 'great flood' of 1691 and the "great sickness" of 1712. The organization of a church—always

an important event in a New England plantation—did not take place until 1691. The town and parish were identical until 1738, when Westbury (now Watertown) was set apart as an ecclesiastical society. Northbury (now Plymouth and Thomaston) secured similar rights in 1739, and thenceforth the original parish became known as the First Society. The church belonged, of course, to the Congregational denomination. No other existed in the territory until 1737, when Episcopal services were introduced. The town was represented in the Revolutionary War by about 800 men, an extraordinary number.

Throughout its history, Waterbury has suffered seriously from fires. The losses in 1880-81 and in 1892-94 were exceptionally large, but were far surpassed by those of the great fire of 1902, which amounted to more than \$2,000,000. A fire company was organized in 1828 and several others later, and a fire department was established under the first city charter in 1854. This has developed, much after the fashion of other cities, into a paid department, with a chief engineer, and equipped with a modern automobile apparatus.

**Manufactures, etc.**—The conditions that surrounded the settlement of the town and limited its agricultural prosperity became an important factor in its subsequent development. Under the discipline of poverty and hardship, a group of men grew up who possessed inventive genius, and, in addition, patience, economy and pluck. When the manufacturing era opened, these men were at the front, ready to make use of their opportunities, while the rapid streams of the region furnished the necessary water power. The farmers' sons became manufacturers—makers of clocks and buttons—and along the several streams little factories and mills grew up, whose products met the growing demand of the time. It was in response to this demand, emphasized by the War of 1812-15, that the brass industry of Waterbury received its early impetus—an impetus which was enhanced anew, and very greatly, by the War for the Union. By 1840 the manufacture of sheet metal and wire had taken the lead of all others. But there were many uses to which sheet brass could be applied beside button-making, and Waterbury manufacturers were quick to discover them. The great manufactories are still known locally as "rolling mills," but the articles produced in them are of endless variety. Through the latter half of the 19th-century the bulk of the brass manufacture was carried on by six concerns, one of which came into existence in 1802, and another a few years later. These six manufactories still hold their prominent position, but meanwhile others have sprung up and attained to great importance, some devoted to one specialty and some to another, and several of them rivaling in the extent of their product the older establishments. Buttons, buckles, pins, hooks and eyes, suspenders, harness trimmings, rivets, wire, tubing, gas fixtures, lamps, brass kettles, boilers, clocks, watches, spoons, forks, flasks, percussion caps, photographic materials, coins for South American republics—things of all kinds made wholly or in part of brass—are sent forth from their packing rooms by hundreds of thousands, and shipped to all parts of the world. The chief seat of the brass industry in America is the Naugatuck Valley, and Waterbury is its dominant

centre. There are also many important establishments quite outside of the brass industry—machine shops of national reputation, foundries, manufactories of cutlery, of hinges, of traps, of aluminum goods, paper-box factories and various others. The number of Waterbury concerns which organized under the "Joint Stock Law" of Connecticut between 1843 and 1911 was about 300. One hundred of these were companies working in metals; the rest were corporations manufacturing other materials, or mercantile and miscellaneous concerns. Many of these have ceased to exist, but the surviving corporations number over 150. The fame of the Waterbury watch was worldwide, yet few people know that one of the largest clock factories on the globe is here. In 1845 the capital employed in manufactures amounted to \$653,825; in 1890 the amount of the capital was \$17,682,500, and the value of the product, \$17,712,829; and, in 1910, the amount of the capital was \$35,000,000, the value of the product \$50,350,000, and the total wages paid \$12,000,000. In 1914 the capital was \$49,000,000 and the gross products almost \$51,000,000. Waterbury, having manufactured munitions during the War of 1812, and during the Civil War, again turned to the manufacture of war materials in 1914, and continuously during the World War has turned out munitions to the extent of tens of millions of dollars.

Through all this period Waterbury men were busy as inventors. The first United States patent was granted to a descendant of a Waterbury miller; the second was granted to a resident of Waterbury—in 1796. The number of patents issued to residents of Waterbury continues to be about double what might be expected from the population; or one annually for every 500 inhabitants. The city has six commercial and seven savings banks.

**Railroads and Transportation.**—Electric cars run through the main streets and beyond the city limits in every direction to the neighboring towns. The headquarters of the western division of the New York, New Haven and Hartford Railroad are in Waterbury and express train service is given both to New York and Boston with local service on branches extending to Middletown, to New Haven and to Watertown. The electric trolley railway system centring here serves 42 towns within a radius of 35 miles. The product of the Waterbury manufacturers in the line of mailable goods is so immense that the business of the post office is exceptionally large. The money order business amounts to nearly a million dollars annually.

**Water Supply, Lighting, etc.**—The water supply is abundant and good. A reservoir was established on East Mountain in 1868, another on Cooke street in 1880, the Wigwam Reservoir in 1901, and in 1909 the building of the Morris Reservoir on the west branch of the Naugatuck, 11 miles north of the city, was begun. These reservoirs have a total capacity of over 5,000,000 gallons of water. There are 95 miles of water pipe. A sewerage system was introduced in 1883, but the discharge of sewage into the river was strongly objected to by persons and establishments located below the outfalls. In August 1904 the city began the building of a trunk sewer, and a sewage disposal plant some miles down the valley. The city has been lighted by

gas since 1854. Electric lights were introduced in 1884, and were substituted for gas lights on the public streets not long after. Since 1904 the current which supplies the lights and also furnishes the motive power of the trolley system is brought across the country from the Housatonic River.

**Streets, Parks, Buildings, etc.**—The city is divided into four sections, as the town has been from its settlement, by two main streets, one running east and west, the other nearly north and south. There is also an informal division into districts, some of which represent the school districts of the earlier time. The most important of these are Brooklyn, Waterville, Hopeville and Bunker Hill. At the intersection of the main streets there is a central park or green, adorned with stately elms, at one end of which stands an elaborate soldiers' monument (erected in 1885, by popular subscription), and at the other end a handsome drinking fountain. The development of Hamilton and Chase Parks—valuable gifts to the city—was begun in 1903. Centre square and Union square are attractively laid out. The public buildings worthy of mention are the courthouse, the post office, the Bronson Library, Second Congregational Church, Saint John's Church (Episcopal), Saint Patrick's Church (R.C.), the building of the Young Men's Christian Association, the Girls' Industrial School, the Lilley building, the Citizens' Bank, the Elton Hotel and the Buckingham building, Saint Anne's Church (R.C.). The municipal building adjoining Library Park cost \$600,000. There are 23 theatres. The union railway station is modern and commodious. The Chase Interests, Inc., have just built an edifice costing approximately \$1,000,000, to be used for office purposes.

**Education, etc.**—School affairs were at first conducted by the town, and afterward by a "school society," which divided the town into 14 districts. In 1849, chiefly with a view to establishing a high school (the old academy having suffered a decline), five of the districts were incorporated as a centre district, under the management of a board of education, a finance committee and a superintendent of schools,—leaving a circle of outlying districts under the old management (a board of school visitors). In 1899 the bounds of the city were extended and made coterminous with those of the centre district, and the earlier and somewhat cumbersome organization was superseded by a department of education, consisting of the mayor and a board of seven members. In 1917 the board consisted of the mayor and nine members, three members being elected for terms of six years each. When, in 1902, the city was finally made coterminous with the town, the traditional status of the outlying districts was preserved. The districts have since practically been abolished. The investment in public schools exceeds \$3,000,000.

Kindergartens, domestic science, manual training and sewing departments have been established in all of the schools, and the evening schools have been conducted since 1856. A continuation school for machine shop apprentices has been established. An open-air school was established in 1912. The first high-school building was destroyed by fire in 1870; the third was erected in 1895-1911 at a cost of \$225,000. Two new high schools have been erected at a cost

of about \$1,000,000 each and a third has been begun to cost the same. Pupils enrolled in the public schools for 1918 number 14,748 and in schools other than public 6,184. These other schools include Saint Margaret's School for Girls (the diocesan school of the Episcopal Church), the Academy of the Convent of Notre Dame, five large parochial schools and various smaller schools. The Bronson Library, founded in 1868 by a bequest of \$200,000 from a native of the town, contains more than 100,000 volumes, and has a very wide circulation every month. The present building was erected in 1893-94, at a cost of \$63,500.

There are three daily newspapers—the *Waterbury American*, established in 1844; the *Waterbury Democrat* and the *Waterbury Republican*, both dating from 1881. The town has made a very respectable record in pictorial art, sculpture, music and literature.

**Societies.**—Various literary, musical and scientific societies and social clubs have been organized, the most active of which are the Waterbury Club, incorporated in 1881; the Women's Club, established in 1889; the Daughters of the American Revolution, 1893, the Naturalists' Club, 1897, the Mattatuck Historical Society, organized in 1877 and incorporated in 1902 and the Country Club, incorporated in 1908. The various Masonic bodies and mutual benefit fraternities number about 175. The Young Men's Christian Association, organized in 1858, occupies a building which cost \$40,000. Other philanthropic organizations are the Industrial School (for girls), the Boys' Club, the Young Women's Friendly League, two day nurseries, a free kindergarten, Protestant and Roman Catholic temperance societies and the Southmayd Home (for aged persons). Waterbury has three large modern hospitals, the Waterbury Hospital and the Saint Mary's Hospital, costing considerably over one-half a million dollars. The present almshouse was built in 1893 at a cost of \$80,000. Of the several cemeteries of the town, Riverside (opened in 1853) is noteworthy for its picturesqueness and for its monuments. A memorial chapel stands at its main entrance.

**Religion.**—Waterbury contains 38 churches and three Union chapels. Probably two-thirds of the population are Roman Catholics and the Catholic churches number 10. Five of the Protestant churches are Congregational, three Episcopalian, four Baptist, five Methodist, three Lutheran and one Adventist. There is also a corps of the Salvation Army, a society of Christian Scientists and two Jewish synagogues.

**Government.**—In 1825 the population lying around the centre of the town was organized into a borough. The incorporation of the city took place in 1853, with a population of about 4,000. A new charter, obtained in 1871, was superseded by another in 1896, to which important amendments were made in 1899 and 1902. Under this third charter the city is divided into five wards and the government is conducted by a mayor and 15 aldermen, through a number of boards, each having charge of one of the following departments: Of public works, of public safety, including the police and fire departments, of public health, of charities, of education, of finance; also a board of assessors, a board of relief and a board of agents of the

Bronson Library. There are also superintendents of streets, of the waterworks and of sewers and a city engineer. Besides the police court, there is a district court, which has jurisdiction beyond the limits of the city and sessions of the Superior Court are held in Waterbury.

**Population.**—The successful conduct of manufactures so extensive and varied in an inland Connecticut valley has involved a large and steadily increasing immigration. The growth of the city since 1850 has been greatly augmented by the steady inflow of foreigners. The population in 1790 numbered 2,937; in 1850, 5,137; in 1860, 10,004; in 1880, 17,806; in 1890, 28,646; in 1900, 51,139. The United States census of 1910 reported the population at 73,141, the percentage of increase being 59.5. The official estimate of 1915 was 87,745 and the local estimate of 1919, 105,000. The percentage of residents of foreign birth or parentage is, with one exception, the largest of any Connecticut town and the number of nationalities represented is remarkable. At the same time, the condition of the community, socially and morally, is exceptionally good. Waterbury is noted for the superior grade of the homes of its working people. Wealth is more uniformly distributed than in most cities, the question frequently arising whether there are any millionaires in the community. The valuation of property, real and personal, in 1918 was \$110,000,000.

**Bibliography.**—Bronson, 'History of Waterbury' (1858); Bassett, 'Waterbury and Her Industries' (1888); Anderson, 'The Town and City of Waterbury from the Aboriginal Period to the Year 1895' (1896); also 'Charter and Ordinances of the City of Waterbury' (1902) and the annual 'Municipal Register.'

LEROY M. GIBBS,

*Secretary, Waterbury Chamber of Commerce.*

**WATERBURY**, Vt., town in Washington County, on the Waterbury River and on the Central Vermont Railroad, about 11 miles northwest of Montpelier. It contains the villages of Waterbury and Waterbury Center. The location, in a beautiful valley, is most picturesque. The principal manufacturing establishments are grist and lumber mills, brick works, tannery, boot and shoe factory, sleigh and carriage works. There are six churches, Green Mountain Seminary, a State Insane Hospital and graded schools. Pop. 3,273.

**WATERCOURSES**, in law, streams of water usually following a well-defined channel and emptying into some other body of water. A watercourse need not maintain a constant current, but it must be more than an occasional stream, the result of unusual rains or the melting of snow and following a channel customarily dry. See RIPARIAN RIGHTS.

**WATEREE**, a river of South Carolina, formed by the junction of the Catawba River and Fishing Creek, and is called the Catawba in the upper part of its course. It is about 315 miles long and runs nearly southward, forms the east boundary of Chester, Fairfield and Richland counties, and unites with the Congaree River at the southwest extremity of Sumter County to form the Santee River.

**WATERFALL**, a sudden descent in the water of a river or stream from a higher to a

waterfalls. The most noted falls are a 300-foot one at the mouth of the river, and a 200-foot one at the mouth of the river. The latter is a cascade, and is the most beautiful and best preserved of any north and running down the river, rapid is commonly met. Some of the most beautiful are remarked to be those which, while others are noted for the fall of immense quantities of water. The most remarkable waterfall in the world is Niagara Falls, on the Niagara River, about 1600 feet high and 1000 feet wide, and thousands of acres from all parts of the world have devoted the volume of these falls. Waterfalls are now being utilized to furnish both power and water for agricultural purposes. The falls discovered by Dr. Livingston in Africa and named by him Victoria Falls, the falls of the Pukonofa in Norway, the Cascade of Cataract in the Pyrenees and the falls of the Rhine are among the most beautiful in the world, and justly celebrated. Falls are characteristic of a youthful stage of river erosion, and are usually caused by unequal hardness of the rock, the softer being worn down the faster, and giving rise to inequalities in the river bed. After the softer beds are cut down as low as they can be eroded, the rivers more slowly cut away the harder layers, and the fall gradually disappears. For a fuller description see CATARACTS.

**WATERFORD, Conn.**, village and township in New London County, three miles southwest of New London, on the New York, New Haven and Hartford Railroad. There are granite quarries and manufactures of paper. Pop. 3,097.

**WATERFORD, Ireland**, capital of County Waterford and a county city, about 100 miles southwest of Dublin, on the right bank of the Suir, connected with its north suburb of Ferrybank by a bridge. Of six Catholic places of worship, including a cathedral, the finest is the Dominican Church of Saint Saviour, erected (1878) in the Italian style; the Protestant Episcopalians have also a cathedral and two churches. Other buildings are the Protestant Episcopal palace, the Catholic College of Saint John, Saint Dominic's Industrial School, four convents, a town hall, market house, etc. Considerable sums have been expended in deepening the channel of the Suir, whose south bank is fringed for a mile by a spacious quay, while on the Kilkenny side is a shipbuilding yard, with a patent slip, graving bank and dock. Besides two immense bacon-curing establishments, Waterford has iron foundries, flour mills, breweries, etc. A memorial of Waterford's foundation by the Danes in the 9th century is "Reginald's Tower" (1003), which has witnessed the city's capture by Strongbow (1170), the repulse of Cromwell and surrender of Ireton (1649-50) and the embarkation of James II after the battle of the Boyne (1690). Pop. 27,000.

**WATERFORD, N. Y.**, village in Saratoga County, on the Hudson River at the mouth of the Mohawk River and on the Champlain Canal and the Delaware and Hudson Railroad, two miles above Cohoes and 10 miles north of Albany. It has extensive water power and is a manufacturing village. The chief manufactures are knitting mill, toundry and machine shops, fire engine shops, paper and

four mills, boiler works, shirt and machine and a furniture factory. The value of the finished products exceeds \$3,000,000. It has a union free school, two parson elementary schools, free libraries, two newspapers and one private bank. About 4,000.

**WATERHOUSE, Alfred**, English architect: b. Liverpool, 19 July 1830; d. L. 22 Aug. 1905. He studied architecture Richard Lane in Manchester and after in France and Italy. He began practice in Manchester in 1853 and first made his name in the Assize Courts of that city the same year; he afterward designed scenery for Owens College, the town Saint Mary's Hospital and other buildings; other parts of England he was responsible for the following among other buildings, in pool, Seaman's Orphanage, Turner's Home, Royal Infirmary and University College; in London, Natural History Museum, New Saint Paul's School, City and Central Institution, King's Weigh Chapel and University College Hospital Oxford; Balliol College (partly rebuilt) Cambridge, Caius and Pembroke Colleges (partly rebuilt); in Leeds, Yorkshire College the mansions of Eaton Hall (Cheshire) throp (Oxford), and Iwerne (Dorset). He was elected A.R.A., in 18 R.A., in 1885, and in 1898 became treasurer of the academy. He received a Grand Prix at the Paris exhibition of 1867 and was a member of various foreign academies. In 1867 he was awarded the gold medal of the Royal Institute of British Architects, of which he was president 1888-90.

**WATERHOUSE, John William**, English painter: b. Rome, Italy, 1849. He studied at the Royal Academy and his paintings noted for the richness of their color. His paintings include 'The Oracle' (1887), 'Magic Circle,' 'The Lady of Shalott,' 'Belle Dame sans Merci,' 'The Soul Rose' and 'Thisbe.'

**WATERLAND, Daniel**, English man: b. Lincolnshire, 14 Feb. 1683; d. 1740. He studied at Cambridge, was master of Magdalen College, chaplain to George I and canon of Windsor. He was an able defender of the Orthodox faith against the Deists. His chief works are 'A Vindication of Christ's Divinity being a Defense of some Queries relating to Dr. Clarke's Scheme of the Holy Trinity' (1719), followed by a second (1723) and a third (1725) 'Vindication'; a 'Critical History of the Athanasian Creed' (1724), also directed against Clarke; 'Christianity Vindicated Against Infidelity,' a reply to Tindal's 'Christianity as old as the Creation'; and a 'Vindication of the Doctrine of the Eucharist' (1731) directed against Hoadley's rationalistic view of that ordinance. Consult Van Milneburg's 'Daniel Waterland' prefixed to W. Waterland's 'Works,' in 6 vols. (1843).

**WATERLOO, Stanley**, American journalist: b. Saint Clair County, 21 May 1840. He was graduated from the University of Michigan in 1869, and his journalism, was one of the most

Saint Louis *Journal* in 1872, was subsequently editor of the Saint Louis *Republic*, *Chronicle*, and *Globe-Democrat*, and in 1884 established the *Saint Paul Day*. He was later editor-in-chief of the *Chicago Mail*, and has been engaged on various other journals. He has written 'A Man and a Woman' (1892); 'Honest Money' (1895); 'These are My Jewels' (1902); 'The Cassowary' (1906), etc.

**WATERLOO**, Canada, (1) a town of Waterloo County, Ontario, two miles northwest of the capital, Berlin, on a tributary of the Grand River, and on a branch line of the Grand Trunk Railway to Elmira. It is an industrial centre, with iron foundries, manufactures of agricultural implements, boots and shoes, brooms, textiles and tobacco and a newspaper. Pop. 4,800. (2) The capital of Shefford County, Quebec, and a railway junction, on the Stanstead, Shefford and Chambly Railway, 70 miles east by south of Montreal. It has lumber and flour mills, a brewery, tanneries and manufactures of mill-machinery, agricultural implements, iron castings and furniture. There are two newspapers and two banks. Lumber and farm produce are shipped. Pop. about 2,000.

**WATERLOO**, England, a town and watering-place of England, on the Lancashire Coast, four miles north-northwest of Liverpool, forming with Seaforth one urban district. Pop. 27,000.

**WATERLOO**, Ill., city, county-seat of Monroe County, on the Mobile and Ohio Railroad, 24 miles south of Saint Louis, Mo. It is in a fertile agricultural region, in which the chief products are wheat and corn. In the vicinity are quarries of fine building stone, known in the trade as Waterloo marble. The chief manufacturing establishments are flour mills, marble works, a large brewery, an ice factory and bottling works. There are large stock yards and coal and lumber yards. The educational institutions are a high school, founded in 1891, Saint Joseph's School (Roman Catholic), public and parish elementary schools and a school library. There are two banks and two newspapers. Pop. 2,091.

**WATERLOO**, Ind., town in De Kalb County, on the Cedar Creek, and on the Lake Shore and Michigan Southern Railroad, 28 miles north by east of Fort Wayne. It is the commercial centre of an extensive agricultural section, in which wheat, corn and vegetables are the chief products. It has seven churches, a high school, founded in 1872, graded elementary schools, two banks and a newspaper. It was founded in 1857, and in 1864 was incorporated. Pop. 1,167.

**WATERLOO**, Iowa, city, county-seat of Blackhawk County, on the Cedar River, and on the Illinois Central, the Chicago, Rock Island and Pacific and the Chicago, Great Western railroads, about 95 miles west of Dubuque. It is in an agricultural and stock-raising region, and has considerable manufacturing interests, partly due to abundant and cheap water power. The chief manufacturing establishments are foundries, machine shops, gas-engine works, threshing-machine factories and automobile works, manufactures of refrigerators, farm implements and

the Illinois Central Railway repair shops. Their annual gross products are valued at about \$4,000,000. The principal public buildings are the government building, the county courthouse, municipal buildings and the Presbyterian Hospital. There are 31 church buildings. The educational institutions are two public high schools—the East High School, founded in 1872, and the West High School, in 1870; Our Lady of Victory Academy (Roman Catholic), public and parish elementary schools, Waterloo Business College and school libraries. There are seven banks and two daily newspapers, besides monthly and semi-monthly periodicals. The government is vested in a mayor and a council of eight members elected biennially. The majority of the inhabitants are American born; of the foreign born the Germans predominate, then the Irish and the Scandinavians. Waterloo was settled in 1845-46 by G. W. Hanna and Charles Mullan. It was incorporated as a town in 1868. Pop. 38,000.

**WATERLOO**, N. Y., village, one of the county-seats of Seneca County, on the Seneca River, the Cayuga and Seneca Canal and on the New York Central and Hudson River Railroad, about 18 miles west of Auburn and 55 miles east of Rochester. It is in an agricultural region, but the village has several manufactures, chief of which are large woolen mills, lumber mills, piano factories, wagon and carriage works. It has a high school founded in 1843, public elementary school and a public library. There are two banks and three newspapers. Pop. 4,343.

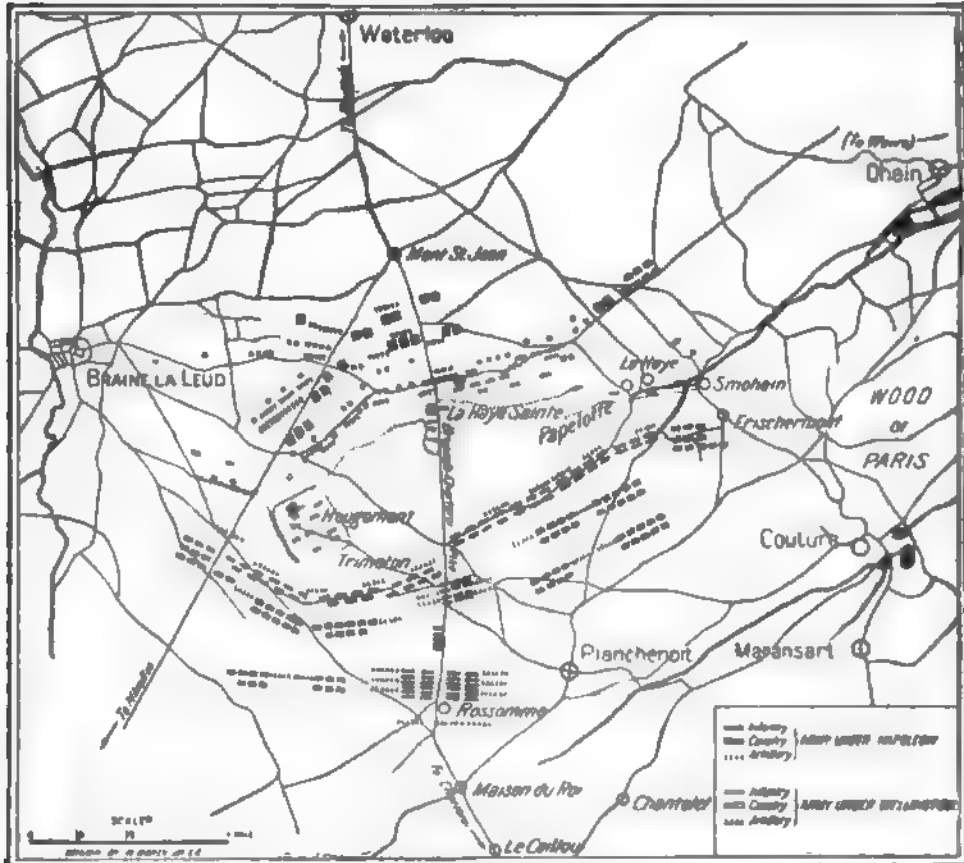

**WATERLOO**, Battle of, the culminating engagement of the shortest and most decisive of all of the Napoleonic campaigns, was fought 18 June 1815, near the village of Waterloo, in Belgium, situated about 12 miles south of Brussels. From 11 April 1814, when Napoleon signed the first abdication and retired in exile to Elba, until 20 March, when he terminated the period of that retirement and returned to Paris, the political and domestic affairs of France had been bordering on revolution. Although the administration of affairs by the government established by the Comte du Provence, who, under the title of Louis XVIII, had taken unopposed possession of the country, restored political liberty, the changes inaugurated were so sudden, that it unsettled all domestic affairs, the title of estates, the position of public men, and the prospects of the army to an intolerable extent. A general sense of alarm and humiliation prevailed among all classes, and even a Napoleonic period seemed preferable to the existing conditions. To add to the general turmoil, about 300,000 troops who had been held as prisoners in the various German fortresses were released under treaty stipulations and returned to France. Their apparent availability for further operations soon formed the basis for innumerable military plots of which that designed by Fouché, with the ultimate object of placing either the Duke of Orleans or the king of Rome upon the throne, was the most important.

Napoleon was fully conscious of the existing state of affairs. France was down, groveling at the feet of the Allies. Here was the

opportunity for a truly patriotic action. He would give popular liberty to imperial France, and henceforth devote all his energies to strengthen that liberty and increase that prosperity. He counted upon the enthusiastic support of the army which was fretting under the command of emigres who had once fought against France, but were then being appointed to important commands, and felt sure of the effect of his tremendous military fame upon the general military feeling of the country. He thought of Marengo; how in three short months he had lifted France and himself from

army amounted to about 500,000 men, on paper, but only about 200,000 men were available for actual field service. In planning the campaign, Napoleon had the choice of confining himself to purely defensive operations and allowing the Allies to invade France, or of assuming the offensive, and relieve her of the consequences of a second invasion. He chose the latter, and laid the scene of the campaign in Belgium where the English under the Duke of Wellington had their headquarters at Brussels, and the Prussians under the command of Marshal Blücher, at Namur.

Field of Waterloo. (Showing positions of the two armies at 11 A. M., 18 June 1815.)

the lowest ebb of fortune up to the highest pinnacle of military glory and power. He judged correctly in all these things. He left Elba 20 February, and landed on the coast of France 1 March, and entered Paris triumphantly 20 days later.

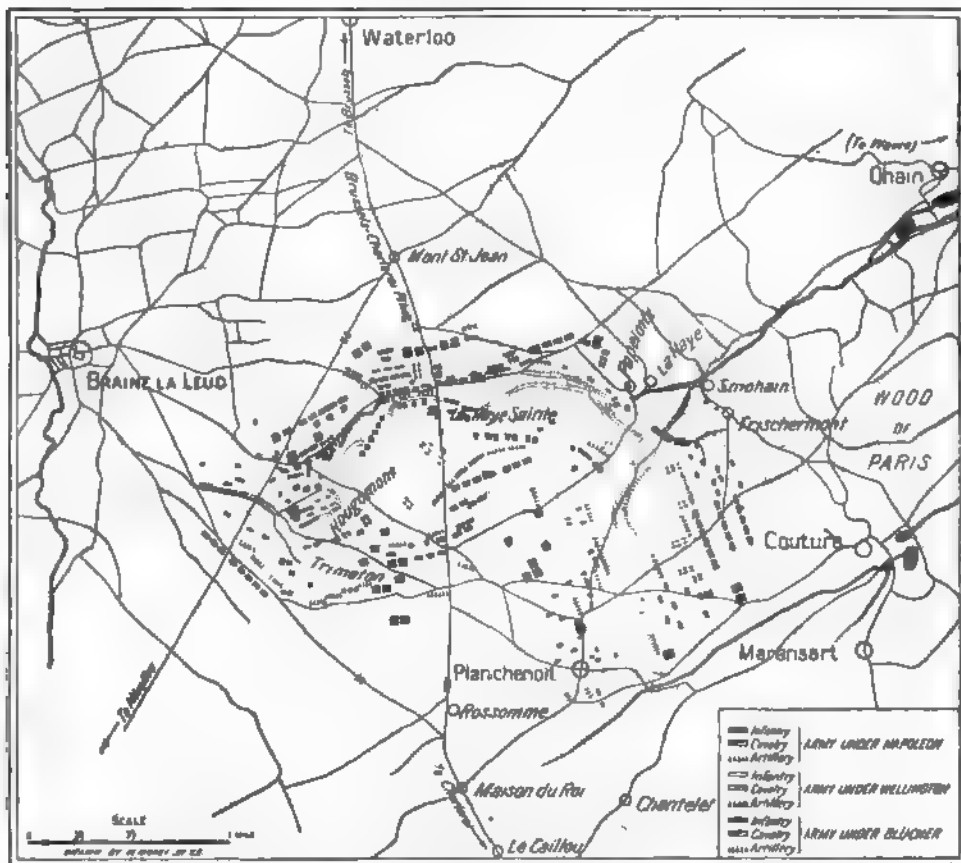

While Napoleon was inaugurating the Hundred Days with professions of peace and liberty, the Allied Powers suspended negotiations at the Congress at Vienna, issued a declaration branding him as "an enemy and disturber of the peace of the world," and formed a new Coalition to renew the struggle against him. By the beginning of June they had more than 700,000 men in the field, and he was compelled to take active measures to defend his newly recovered empire. The French

The general plan of operations was based upon his favorite form of strategy — action on "interior lines" against the two armies opposed to him. He assumed that Wellington and Blücher would endeavor to form a junction at Charleroi, and determined to concentrate the bulk of his own army at that point and defeat them separately before they could effect that junction, and then turn his attention to the force of Austrians and Russians gathering on the eastern border under the command of Prince Schwarzenberg.

At the beginning of the campaign the French army numbered 124,588 men — 89,415 infantry, 23,595 cavalry, 11,578 artillery with 344 guns. Wellington commanded 93,717 men — 69,829 infantry, 11,879 cavalry, 9,406 artillery and

engineers, with 196 guns. The Prussian forces under Blücher amounted to 120,954 men—99,715 infantry, 11,897 cavalry and 9,360 artillery, with 312 guns. Wellington's forces, composed of Englishmen, Dutch, Belgians, Nassauers, Germans and Brunswickers, were stationed in numerous cantonments scattered over a large area around Brussels, and to the westward of the Brussels-Charleroi pike leading to the south, with the coast as their base. Of Blücher's force the First corps, under Ziethen, was at Charleroi, the Second, under Pirch, at Namur, the Third, under Thielmann, at Ciney

tacked the Prussians at Ligny, and after three hours of severe fighting, defeated them and captured 21 guns. The battle was desperate and bloody; about 12,000 Prussians fell, and in the final charge of the Guard, Blücher himself was wounded. This was Napoleon's last victory. As the result of the battle, he assumed that the Prussians had been routed and were retreating to their base by way of Namur and Liège, when, as a matter of fact, under the direction of Gneisenau, Blücher's chief of staff, they were moving northward and converging on Wavre, with the intention of join-

Field of Waterloo. (Showing positions of the three armies at 7 30 P. M., 18 June 1815).

and the Fourth, under Bulow, at Liège, with the Rhine as their base.

The movement began on 13 June. The French army advanced rapidly northward, crossed the Sambre on the afternoon of the 15th, attacked Ziethen's position, drove him back upon Fleurus, and occupied Charleroi. A portion of the army then continued the advance through Gossillies to Quatre-Bras where they met a force of 25,000 men under Wellington, on the afternoon of the 16th, and after several hours of hard fighting were driven back upon Frasnes. In the meantime, with the intention of blocking the road between Quatre-Bras and Sombreffe so as to separate the forces under Wellington and Blücher, the troops commanded by Napoleon himself at-

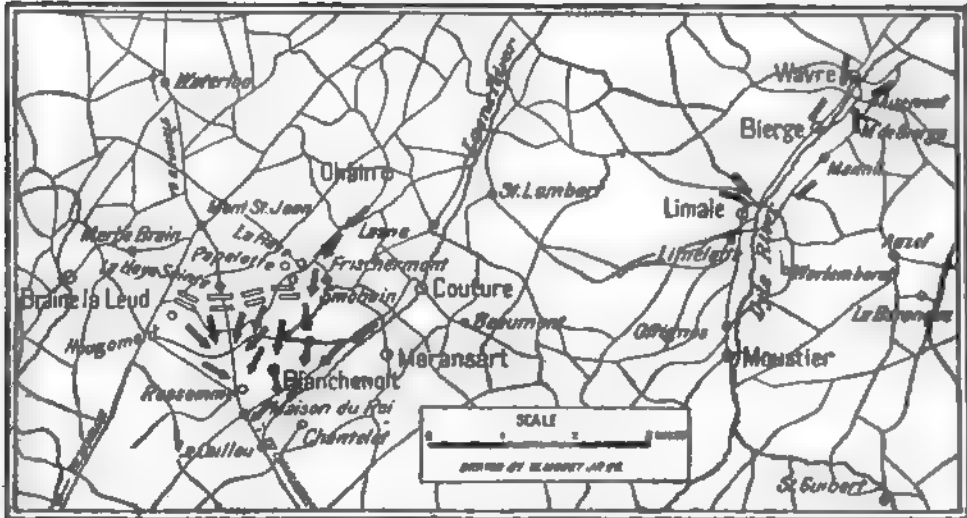

ing Wellington, with whom they were in constant communication. About noon of the 17th, Napoleon detached Grouchy with 33,000 men to pursue and complete the defeat of the Prussians driven back at Ligny, while he himself with the main body of the army joined Ney and followed Wellington, who, although victorious at Quatre-Bras, had been forced to fall back northward toward Brussels on account of the defeat of the Prussians at Ligny. Wellington's retrograde movement was continued during the whole of the 17th, until he had reached the heights of Mont Saint Jean, about four miles south of the village of Waterloo, where the Prussians could join him by way of Ohain and Wavre. Here he selected his position, and confident of their assured

support, he awaited the advance of the emperor.

On the afternoon of the 17th, when Napoleon reached Marbain, he received the information that the Prussians defeated at Ligny had not retreated to Namur and Liège, and he sent a message to Grouchy informing him of that fact, and instructing him to find out if the Prussians were moving to a junction with Wellington. When Grouchy received this message he was actually farther from the Prussians than the Prussians were from Wellington, and about the time he reached Gembloux, about 10 o'clock on the night of the 17th, only

rear of Wellington's position, and thus cut off his retreat in the direction of Brussels and his base of supplies. The best authorities concede that the plan was admirably conceived.

About 8 o'clock on the morning of the 18th, Wellington drew up his forces in line of battle, but although the rain which had been falling all night ceased about that time, the attack by the French was postponed so that the ground might be in better condition for artillery movements. A little before 9 o'clock Napoleon reviewed his lines, and about 10 o'clock he sent instructions to Grouchy to advance upon the Prussians at Wavre. The battle commenced

General Map. (Showing positions of the three armies at 8 A. M. June 1815.)

to learn that the Prussians had really marched to Wavre, the main French army had reached the field of Waterloo and bivouacked opposite the forces of Wellington. It was past midnight when Napoleon inspected the position of both armies. The main line of Wellington's forces occupied an advantageous position along the highway that runs from Braine la Leud to Wavre by way of Ohain, with the centre resting on the Brussels-Charleroi pike, while strong outposts held the farm house of La Haye Sainte directly in advance of the centre, the hamlets of La Haye, Papellotte, and Smohain on the extreme left, and the chateau of Hougomont on the right. His force consisted of 67,661 men—49,608 infantry, 12,408 cavalry and 5,645 artillery with 156 guns. Of these the British troops numbered only about 24,000. Napoleon had 71,947 men—48,950 infantry, 15,765 cavalry and 7,232 artillery with 246 guns. He arranged his troops in two lines diagonally across the Brussels-Charleroi pike, the right resting on Frischermont, and the left across the road to Nivelles, with a strong force of infantry, cavalry and artillery stationed in the rear on both sides of the Charleroi pike near Rossomme.

Early on the morning of the 18th, he dictated his plan of battle, the direct object of which was to capture the village of Mont Saint Jean lying on the Charleroi pike directly in the

at 11.30. As a diversion, a division of Reille's corps assaulted the British position at Hougomont, were repulsed, and were supported by division after division until the entire Second corps were in action against Wellington's left, and therefore did not take any part in the main attack on the British centre by D'Erlon about 1.30. In this attack, the advanced troops of the British right, composed of Bylandt's brigade, were easily routed, but the advancing French received a terrific fire from Picton's brigade, and being charged by the British cavalry, fell back in great disorder. Here General Picton who probably commanded the British right was killed. In the meantime, assault upon assault was made by the French on La Haye Sainte, which occupied the greater part of the afternoon, while for two hours, from 4 to 6 o'clock, under the personal direction of Ney, the splendid cavalry divisions of the French were hurled against the British right-centre, but failed to break the formation of a single British square. The cavalry attack being unsupported by infantry, Ney was compelled to withdraw for lack of troops, about 6.30, just as La Haye Sainte was taken, too late to be of any advantage. About the middle of the afternoon Napoleon discovered the advance guard of the re-enforcing Prussians on the hills of Saint Lambert about three miles away upon his right, and realized for the

first time that the entire Prussian force had succeeded in concentrating at Wavre, and were now on hand to aid Wellington. He immediately detached Lobau with the Sixth corps, to intercept the new enemy, and sent a message to Grouchy, ordering him to return. Grouchy in the meantime, having moved off to Wavre in search of the Prussians, did not get this message until evening.

Lobau being unable to check the advance of the Prussians, the Young Guard was sent to re-enforce him, and then, believing that his night was secure, Napoleon massed the eight remaining battalions of the Imperial Guard for a final attack upon Wellington's centre. Supported by a terrific artillery fire, and led by Friant, the Guard advanced, while D'Erlon hurled the First corps against the British right. D'Erlon's assault was effective, but the Guard, decimated by a heavy fire from Maitland's brigade, supported by those of Halkett and Elphinstone, were repulsed with terrific loss and fell back in complete disorder before the impetuous charge of the 52d regiment. Just then, about 7.30, the main body of the Prussians arrived, and going right into action, attacked the French right and threw it into confusion. At that moment, Wellington, seeing that victory was assured, ordered a general advance of his lines and decided the contest. His troops, however, were too far gone to engage in the pursuit, which was taken up by the Prussians with vigor, and the retreat soon became a rout. Napoleon left the field in the centre of a square of the Imperial Guard. He left this at Genappe, and arrived at Charleroi at daybreak with a small escort of horsemen. He reached Paris 21 June, and signed the second abdication on the 22d. The entire campaign had lasted but three days, and the battle itself, one of the most remarkable and terrible of modern times, was decided in eight and a half hours. The French lost in killed, wounded and missing, about 31,000 men, and the Allies, about 23,000.

**Bibliography.**—The literature upon the subject is very extensive, but for the most reliable and exhaustive information consult Ropes, J. C., 'The Campaign of Waterloo' (New York 1892); Chesney, 'Waterloo Lectures' (London 1874), and Gardner, 'Quatre-Bras, Ligny and Waterloo' (London 1882).

**WATERMAN, Nixon**, American author: b. Newark, Ill., 12 Nov. 1859. He was connected with the *Omaha World-Herald* and *Bee* 1887-90; with the *Chicago Herald* and *Post* 1890-93, and since 1895 has been engaged in literary work. He is the author of 'A Book of Verses' (1900); 'In Merry Mood: a Book of Cheerful Rhymes' (1902); 'The Whistling Girl,' a comedy (1902); 'Cap and Bells' (1903); 'Io from Iowa' (1911).

**WATERMELON.** See **MELONS.**

**WATERPROOFING**, the art of rendering various substances impervious to the penetrating action of water. The purposes to which waterproofing is now applied are very numerous and the methods range from the early use of lead for sheathing building foundations, of tar for tarpaulin, oil for oil-skin, rubber for clothing, to various painting processes which claim for bases, substances capable of resisting the natural

action of the elements, and which, invisible, impenetrable, insoluble and imperishable, effectually render brick, stone, marble, terracotta, stucco, concrete, etc., impermeable to water. These processes are used to waterproof and insulate exterior and interior walls of buildings, for cold storage plants, for the lining of reservoirs, for monuments, etc.

Among the numerous methods of waterproofing, many of which are protected by patents, the greater number in general relate to a surface application of some composition, usually somewhat thicker than an ordinary liquid solution. The more widely known methods of waterproofing are those used in connection with paper and paperboard, textile fabrics, cloth, with cordage, leather, etc.

**Paper.**—The commonest process for waterproofing paper and manufactures of paper is their saturation with wax or paraffine; either by the use of heat, or in solution, as with benzol. Flexible papers (and woven fabrics also) of an absorbent nature may be made waterproof by a half-and-half mixture of a vegetable oil—such as China wood oil, linseed oil, poppy seed oil or soya bean oil—with polymerized cumarone. The mixture is heated for a time, and after being allowed to cool, is dissolved in a volatile solvent, which is applied with a brush, or by dipping the material into the solution and draining off the surplus. This treatment does not affect the folding qualities of papers, practically doubles the tensile strength, and renders the sheet transparent. One of the newest methods, recently patented, consists in saturating the paper with an ammonia soap of stearic acid emulsified with paraffine and diluted with water. The paper is passed through a tank containing the emulsion, and thence is taken over a series of drying rolls to evaporate the water. A French process recently introduced consists in coating the paper with a vegetable mucilage, and, after this is dry, applying a coat of agar-agar. The paper thus prepared is then subjected to the steam arising from a bath made by adding four pounds of formol and five pounds of potassium bichromate to six quarts of water. This process renders the paper somewhat brittle, and to restore flexibility it is sponged with a weak dilution of glycerine. The so-called Japanese waterproof paper is made by pasting two sheets of paper together, the fibres crossing, with a secret waterproof cement.

**Textiles.**—Water-repellent textiles may be grouped into two classes according to their nature, first, the coarser tissues used for awnings, tents, oil-skins, tarpaulins or canvas coverings for exposed merchandise, etc.; secondly, the finer tissues employed for the manufacture of waterproof clothing. The processes employed are of two classes, mechanical and chemical. In the first, a solid layer of some impermeable substance is laid upon the material. The substances usually applied are india rubber, varnish, resin, pitch, tar, paints, etc. These are also impervious to air. The agents in use for chemical waterproofing are aluminum sulphate, common alum, lead acetate, copper sulphate, zinc sulphate, iron sulphate, ammonium cuprate, potassium chromate, paraffin, ceresine, wax, soap, etc. In waterproofing loosely woven fabrics it becomes necessary to fill up the interstices between the threads with imperviable

material as well as to waterproof the threads themselves. It follows that a textile which is to be waterproofed should be very tightly woven so that when the individual threads are made impervious to water the cohesion of water falling upon it will prevent its separation into particles so small as to be able to pass between the threads. The earliest process consisted in covering the tissue with tar, a method still employed for marine supplies, ropes, cordage and coverings, and which has the advantage of giving solidity to the fibre, and at the same time preserving it. Drying oils, and particularly boiled linseed oil, are still largely used to waterproof coarse tissues, and particularly for the oilskin overalls worn in rough weather by sailors and fishermen. Oiled tissues, however, are heavy and lack comfortable suppleness, while their color and appearance militate against their extended use. One of the more widely employed processes for waterproofing the coarser tissues consists in impregnating the material with an insoluble soap such as those formed with copper, iron, zinc and alumina. Copper soap is most universally used. The material to be waterproofed is first scoured by boiling with soda lye and then washed, after which it is passed through a 20 per cent ammonia soap bath, then immersed in an 8 per cent solution of sulphate of copper. According to its nature, the fibre absorbs a certain quantity, large or small, of copper soap. In the ashes produced by the burning of a square yard of canvas or linen tissue so treated, as much as  $57\frac{1}{2}$  grammes of copper is found, and nearly 29 grammes of copper is to be found in the cinders of the same quantity of cotton tissue. Copper-soap waterproofed materials present a characteristic greenish tint.

The manufacture of waterproofed materials for clothing has attained considerable importance. The fact, however, must be recognized that the results generally obtained are not altogether satisfactory, especially from a hygienic point of view. Absolute waterproofing cannot be obtained without wholly closing the pores of the tissue; thus prepared it is an efficacious protection from rain and from contact with water, in certain cases is of real service, but inconveniently prevents ventilation. While the garments are made watertight they are at the same time made airtight. The perspiration and natural moisture of the body are not allowed to escape, but are held in saturation in the clothing, rendering it impure, damp and uncomfortable. The body is kept damp, and upon removing the outer garments the wearer is liable to chills and colds, hence, such waterproofing is unsuitable for prolonged personal wear.

The most diverse substances can be used for waterproofing textiles, if they are soluble in a liquid other than water, and can be spread over the surface of the material,—if they possess a certain suppleness, and neither alter the fibre nor the color of the tissue. Wax, balsamic gums, isinglass, spermaceti, metallic soaps dissolved in essential oils, a solution of shellac with borax are employed in waterproofing tissues. The cloth, whether of silk, cotton, flax or wool, is usually rendered waterproof by the application of some solution of any of these substances to one or both surfaces. In many of the earlier processes, the cloth was im-

mersed in a liquid, so as to become saturated with the waterproofing agent. An early patent was obtained for a method of rendering cloth waterproof without concealing its textile surface; the cloth in the first place is saturated with a waterproof composition; it is then dried on one side to form a hard film, while the other side is kept moist, and is afterward deprived of its composition by means of spirits of turpentine.

Frequently silk tissues are waterproofed by the use of gelatine rendered insoluble by an alumina soap. The material is impregnated by passing it through cylinders covered with swanskin, afterward being steam dried. Woolen tissues are passed through a solution of acetate of alumina obtained by treating ordinary alum with acetate of lead. The process most extensively in use at the present day is the acetate of alumina treatment. The fabric is steeped in the acetate solution for 12 hours, the temperature being kept at about 95 degrees, special care being taken that it shall not reach 100 degrees. Much difficulty in securing an even distribution of the acetate throughout the fabric is avoided by the use of the "jigger," a machine which takes the cloth on a reel and passes it continuously through a vat containing the chemical, winding it upon another reel. When it has all passed the machine reverses and rewinds the cloth on the first reel; repeating this alternation again and again. By this process the time of saturation is reduced to five hours. A still more effective method of saturation is by the vacuum process. The reel of cloth is placed in an airtight drum and the air is exhausted. The acetate liquor is then allowed to flow in, filling the cylinder. Air pressure to the extent of two and one-half to three atmospheres is applied, and allowed to remain for 45 minutes, when the operation is complete. The cloth then goes to the drying room where the temperature is kept well above 100 degrees, in order that the acetate may be changed by the heat to the insoluble basic acetate of alumina. In this condition the fabric is sufficiently waterproof for most purposes of wearing apparel. If it is required that it be absolutely waterproof, it may be made so by immersion in a 5 per cent solution of soap. An insoluble aluminum soap is formed on the fibre of the textile and adheres firmly. The fabric will now have a slippery feel, and this is quite objectionable. It is readily removed, however, by passing the goods through a solution of common alum of the strength of 1 degree or one and one-half degrees Beaumé. With some manufacturers it is a practice to add india rubber or paraffin to fortify the protection given by the insoluble aluminum soap. This is readily accomplished, as the soap solution easily forms an emulsion with melted paraffine or with a solution of rubber in a mixture of linseed and palm oils. A highly recommended formula directs that chopped-up india rubber be dissolved in twice its weight of a hot mixture of petroleum and linseed oil; and that to this be added three times its weight of Japan wax. When well mixed, a small quantity of liver of sulphur is to be worked in. This mass is then to be stirred into a boiling mixture of olein, linseed oil and resin. Finally the whole is to be saponified to a neutral soap with caustic

potash lye. The completed mixture should show a 10 per cent content of rubber and from 6 to 10 per cent of palm oil. After immersion, the fabric is calendered by polished steel rolls under heavy pressure. Linen, hemp and cotton require heavier pressure than wool or silk. In this calendering operation care is needed to avoid such extreme pressure that the textile fibres are crushed. Casein is sometimes used in waterproofing certain textiles and colloidion also, but rarely.

Absolute waterproofing of textile materials is obtained by applying to their surface a thin layer of rubber. The first experiments were made in France by Besson in 1793; they were improved upon and perfected successively by Mackintosh and Hancock of Glasgow, Scotland, by Buttire and Guibal in France and by Good-year in the United States. As in the case of Macadam with road surfaces, the successful efforts of Mackintosh perpetuated his name in connection with india rubber waterproof garments. The material is prepared by spreading on the surface a semi-liquid layer of rubber dissolved in benzol then submitting it to the action of heat to evaporate the solvent. Carbon disulphide first employed to dissolve the rubber, was replaced by a mixture of benzol or coal naphtha and essence of turpentine and later by benzol which alone is now used. In the treatment of cotton and linen cloth a small proportion of sulphur is generally added. A thin layer of this rubber solution is spread on the fabric by special machinery, after which the cloth is doubled, pressed and finished in calendars, the waterproof layer being thus in the centre of the finished material. (See RUBBER MANUFACTURES.) The offensive odor of waterproofed rubber garments may be remedied by treating them with aromatized vapors or by dipping them in concentrated infusions of vervain root, of orris root, of lavender, of camomile, etc. Ammoniacal vapor and sulphurous acid can also be successfully utilized to relieve rubbered materials of their penetrating odor. The application of rubber is made on dyed material in thread or in piece. The use of paraffine as an impervious agent allows the tissue to be dyed after being waterproofed. Paraffined tissues do not absorb water, which assumes a spheroidal shape and slides off the surface. The chief objection to paraffine lies in the fact that it is exceedingly brittle at low temperatures and melts readily with ordinary summer heat. Woolen tissues well cleaned by passing through a light and tepid bath of carbonate of soda and soap, are dried, then steeped in a solution of paraffine in petroleum ether, 60 or 100 grammes to the quart. They are afterward passed through roller presses, dried in the open air, and sent to the dyeing vats.

As already pointed out waterproof rubbered textiles are not only impervious to water, but also to air and numerous other methods and processes have been introduced to produce fabrics which, while resisting rain, do not altogether obstruct ventilation. The consecutive dipping of cloths, as already explained, in soap and alum solutions or in gelatine and gall solutions or in a solution of acetate of lead and then in a solution of alumina, are resorted to with more or less success. Algin, obtained from seaweed, has been strongly recom-

mended for the same purpose. One of the most modern processes consists in treating the fibres in the solution before they are manufactured into textiles and the fabric thus produced, while rain-resisting, offers the same ventilation as ordinary materials. "Fibre-mail," as it is called commercially, is described as a clear, colorless substance held in solution for the purpose of treating silks, woollens, cottons, feathers, paper and other materials, so as to render them water-repellent and proof against dampness, mildew and moths. The value of the process is further stated to be by no means limited to the water-repellent qualities given to the goods treated. The application of the solution leaves a coating upon each separate fibre which, by the action of heat, is cured or vulcanized upon and into the fibre, strengthening it and leaving it impervious and elastic. Among other advantages cited are the properties of giving weight and body to the finer textile fabrics, and by this means, where desirable, economizing material, the quality of the goods being greatly improved and never deteriorated; the process also gives lustre and finish to fabrics, being especially valuable for silks, alpaca, etc.; gives elasticity and toughness to the fibres, preventing cracking and breaking qualities valuable for felt hats, silks, etc.; deepens and fastens the colors in dyed goods; resists stains and spots in the lighter and more delicate goods; prevents woods from swelling and warping; preserves painted surfaces; and prevents polished or metal surfaces from rusting.

**Leather.**—"Fibre-mail" is also successfully applied to leather and leather goods. Many compositions, some of them patented, have been long employed, for rendering leather waterproof by filling up the minute pores. Four or five may be briefly described as examples of the whole. Boiled linseed oil, mutton-suet, yellow-beeswax, and common resin are melted together over a slow fire and applied while hot to the leather, which is itself to be made warm. Linseed oil, resin, white vitriol, spirit of turpentine and white oak sawdust are the materials of another composition. Yellow beeswax, Burgundy pitch, turpentine and linseed oil constitute a third. A fourth plan consists in applying to the leather a hot mixture of two parts tallow with one part resin. Another is to first apply a coating of tallow to the leather with a second coating of one part copaiba balsam with two of naphtha. Caoutchouc, boiled for two hours in linseed or neat's-foot oil is also said to be effective.

**Structures.**—Paint and silica compounds, oils, varnishes and gums have long been experimented with for the preservation of buildings by waterproofing. The Sylvester process has long been in vogue for stone, brick and cement surfaces. It consists of alternately applying hot washes of soap and alum. Coating buildings with linseed oil has been a favorite method as affording some degree of protection against the deteriorating action of the elements. But linseed oil alone or mixed with colors, varnishes and gums has never proved wholly efficient to prevent the disintegration of stone, the weather staining of brickwork, the crumbling of mortar joints and the efflorescence of soluble salts, contained to a greater or less

degree in all bricks, cement and some varieties of stone; this is owing to the protective materials in themselves being subject both to chemical changes when exposed for a comparatively short time to the weather. When linseed oil alone is used, should there be any lime or alkaline salts in the wall, these immediately saponify the oil and render it useless as waterproofing. The oil soon dries out and leaves a spotted or mottled surface. Paint is often seen peeling off from the mortar joints of a building and from the brick work as well, owing to the same cause, the caustic alkaline properties of the salts of lime saponifying the linseed oil in the paint. Among scores of proprietary secret formulas there are some that are indisputably good and are thoroughly guaranteed by their makers. It is the custom of some architects to call for these applications in specifications.

Dry foundations are necessary in order to prevent moisture from rising by capillary attraction from the damp earth into the bases of walls or stoops. One or more perfectly waterproof courses near the foundations and reaching above the level of the ground, should be introduced as a "sine qua non" to a good building. Otherwise, a constant state of dampness, affecting that part of the structure, is apt to produce staining and disintegration beyond redemption. Cement or slate will not effectually answer this purpose owing to their absorbent qualities. Asphalt, sheet lead, copper or some other non-absorbent material should be used. The modern practice of builders of valuable structures is to construct a waterproof "membrane" completely enclosing the foundation. This is commonly a succession of layers of burlaps cemented together with asphalt and united to the foundation material by the same impervious substance. An elastic felt recently introduced is claimed to be superior to the burlaps. Sheet lead as foundation waterproofing is found in the ruins of Roman buildings 2,000 years old. One of the best processes hitherto employed for waterproofing the exterior and interior surfaces of the walls, is the paraffine compound process. The base of this compound is paraffine wax of special manufacture with refined creosote oil and other substances not disclosed. The method of application is to warm the wall to be treated, to the depth of about one-quarter of an inch, thereby evaporating all moisture and rendering it absorbent of the waxy material. The melted waterproofing is then applied to the warm surface until absorbed into the pores. It there remains for a brief time in a liquid state, penetrating as deeply as the surface is heated and dry and gradually hardens as the surface cools. The pores are thus permanently filled and rendered solid without altering the appearance of the stone, etc., treated. This waterproofing compound thus forced in by heat and becoming solid when cold, is far more durable and effective than superficial applications of cold solutions, oils or paints, applied in the usual manner, which do not penetrate into the material, which soon perish, if they are not previously chipped or rubbed off.

As a preservative of stone and marble, of monuments and statuary, vaults, etc., from the destructive effects of the weather so often ob-

served in cemeteries, the process has proved of great value.

A material successfully used in Europe is a fluo-silicate of magnesia, commercially known as "fluat." Its application both hardens and rainproofs stone, but the effect is not instantaneous, as it takes a year to demonstrate itself. Consult Mierzinski, S., 'The Waterproofing of Fabrics.'

**WATERS, wà'térz, Clara Erakine Clement,** American writer: b. Saint Louis, Mo., 28 Aug. 1834; d. 20 Feb. 1916. She was well known as a writer and lecturer upon art. Her writings include 'Legendary and Mythological Art' (1870); 'Eleanor Maitland' (1881); 'Life of Charlotte Cushman' (1882); 'Stories of Art and Artists' (1887); 'Women Artists in Europe and America' (1903); 'Women in the Fine Arts' (1906), etc.

**WATERS, Territorial.** See INTERNATIONAL LAW.

**WATERS, Underground.** A certain amount of the water that falls on the earth's surface passes underground, the percentage varying with the porosity of the surface materials. This absorption of water is due to the fact that all rocks are somewhat porous and considerably fissured. Sand and gravel deposits are very porous and can store from 15 to 35 per cent of their bulk of water. Sandstones have space between their sand grains, but their porosity varies greatly with size of grain and especially with the amount of cementing material filling the interspaces which, in the case of quartzite and some highly calcareous sandstone, fill these spaces entirely. Most sandstones, however, are porous and many hold from 5 to 10 per cent of their bulk of water. Limestones are only slightly porous, but they are always traversed by joint planes and usually, toward the surface, by channels and caverns. Clays, shales and slates have but little capacity for water and the crystalline rocks, such as granite, have very slight porosity. Crystalline rocks, however, are usually traversed by many joint planes and often by zones of decomposition along which surface waters descend for a greater or less distance. In many districts, also, the crystalline rocks are deeply decomposed by the solution of some of their components, and the resulting "rotten rock" is usually as porous as many sandstones. Many lavas are porous and they usually are extensively fissured. Water passes underground in various ways, of which the following are the most prominent: direct inhibition of rainfall; the sinking of surface flows in passing over zones of porous rock; the spreading of streams laterally into the porous deposits of their valleys; and the percolation of water laterally from the ocean or lakes into the materials of the shore. In all regions it is found that the surface run-off and evaporation do not equal the rainfall, which is evidence of the general inhibition of water. Many streams are observed to diminish in volume and even to disappear entirely in running over areas of porous sandstones, cavernous limestones or especially permeable portions of their beds. In many arid regions waters flow out of the mountains in rocky beds and at once sink in the sands of the valleys. In nearly all river valleys there are

alluvial deposits in which the water extends laterally from the main stream and some water-courses have water only in the sands and gravels of their beds for the greater part of the year.

travel of underground water is slow, averaging about one mile a year in moderately porous sandstone.

In the accompanying figures are shown some conditions of underground waters, which have

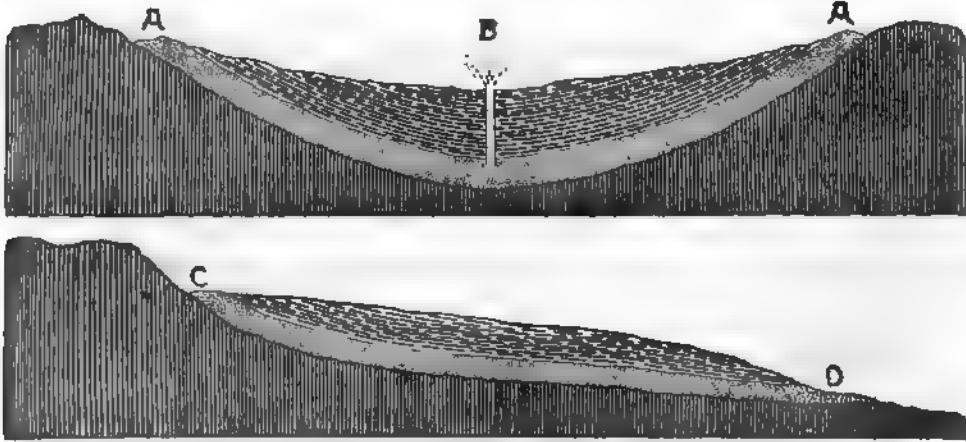

FIG. 1.

Waters present various conditions underground, in some cases flowing to lower levels, through permeable rocks, caverns in limestone or crevices in the harder rocks, to emerge as springs in hillsides, valley bottoms or even out under the ocean, as off the east coast of Florida. Usually the water supply fills an underground reservoir of sand, gravel, porous sandstone, decomposed crystalline rock or fissures. Water under this condition is usually designated "ground water" and its surface level is known as the "water plane." In some cases ground water may occupy strata or follow down crevices for a depth of several hundred feet. Waters which extend far underground are mainly contained in sandstones, and some of these water-bearers are of vast extent and often descend to great depths. Two conditions frequently existing are shown in accompanying cuts. Fig. 1. Cross-sections showing conditions of underground water in permeable rocks. In the first of these sections a bed of sandstones reaches the surface at *A A* where it receives water from rainfall or sinking of streams. This water passes underground below relatively impermeable clay or shale, and an artesian basin is formed which would yield a flowing well at *B B* and at other points where the land is less elevated than at *A A*. In the second section the conditions are somewhat similar, the water entering at *C C* but escaping in springs at *D D*, so there is a constant flow from *C C* toward *D D*. On account of this flow to a lower level there is gradual diminution of "head" of the water from *C C* to *D D*, known as the "hydraulic grade." This condition is found in the Central Great Plains of the United States, where there is a bed of porous sandstone with an average thickness of 200 feet, underlying more than 500,000 square miles and in places lying 5,000 feet deep, and apparently filled with water throughout. Many wells draw artesian supplies from this sandstone and in some areas the flows have a surface pressure of over 200 pounds to the square inch. Hundreds of billions of gallons are contained in this stratum. The rate of

been referred to above. Fig. 2. Sections of a river valley, showing the relations of underground waters. This valley is cut in rock but partly filled with sand and gravel, as shown by

FIG. 2.

the stipple. The river flows on the surface at *A A* but the waters also flow slowly underground in an "underflow" and pass laterally into the sands, filling them to the "water plane" *B B* at the level of the river. Fig. 3. Fissured and de-

FIG. 3.

composed crystalline rock. Surface waters often sink deeply and occur in considerable volume under the conditions shown in this figure. *A A* is the zone of decomposition and disintegration of the rock. *B B* are fissures down which the decomposition has progressed still deeper. This condition is found over wide areas in the Piedmont region of the eastern United States.

N. H. DARTON,  
United States Geological Survey.

**WATERSHED.** See RIVERS.

**WATERSPOUT**, a meteorological phenomenon frequently observed at sea, and analogous to the whirlwinds experienced on land. It occurs when opposite winds of different temperatures meet in the upper atmosphere, whereby a great amount of vapor is condensed into a thick black cloud, to which a vortical motion is given. This vortical motion causes it to take the form of a vast funnel, which appears to descend near the surface of the sea, creates

a partial vacuum at the centre and draws up the water in its vortex, which joins in its whirling motion. The dark cloud above does not in fact descend, as is usually stated by observers, the column being formed by the visible condensation of the moisture in specially ascending air-currents. The whole column, which after the junction extends from the sea to the clouds, assumes a magnificent appearance, being of a light color near its axis, but dark along the sides. When acted on by the wind the column assumes a position oblique to the horizon, but in calm weather it maintains its vertical position and is carried along the surface of the sea. Waterspouts seldom last more than a few moments and are not as a rule dangerous to passing vessels. Firing a projectile into one has not been observed to give any appreciable results. Compare **CLOUDBURST**; **TORNADO**. Consult the publications of the United States Weather Bureau.

**WATERTON**, Charles, English naturalist: b. Walton Hall, Wakefield, 3 June 1782; d. 27 May 1865. He was educated at the Roman Catholic College at Stonyhurst, where he showed a great taste for natural history. He spent many years in travel, and in 1825 published 'Wanderings in South America, the Northwest of the United States, and the Antilles in the years 1812, 1816, 1820, and 1824,' a book which has had great popularity. An illustrated and slightly altered edition was published under the direction of J. G. Wood in 1879. His only other publication is 'Essays in Natural History, with an Autobiography.' These appeared originally in three series (1838, 1844, 1857). In 1870 Norman Moore produced a new edition of them, together with some of his letters and a life. He lived a secluded life for many years at Walton Hall, where he formed a curious collection of animals.

**WATERTOWN**, Conn., town in Litchfield County, on a branch of the Naugatuck River, 27 miles southwest of Hartford, and on the New York, New Haven and Hartford Railroad. It was settled in 1677. There are manufactures of silks, hardware, wire goods and novelties. Pop. 3,850.

**WATERTOWN**, Mass., town in Middlesex County, on the Charles River, and on the Boston and Maine Railroad, eight miles west of Boston. It contains the villages of Bemis, Watertown and Mount Auburn. It is connected with Boston and many of the suburban towns by electric railways. It was first incorporated in 1630. It has a number of manufacturing establishments, chief of which are woolen mills, hosiery works, starch and needle factories. At the United States arsenal located here a large amount of modern ordnance work is produced. The famous Mount Auburn (q.v.) Cemetery is in the town of Watertown. There are two banks, one national and one State, and two weekly newspapers. Pop. 16,515.

**WATERTOWN**, N. Y., city, county-seat of Jefferson County, on the Black River, about 10 miles from its entrance to Black River Bay, an arm of Lake Ontario, and on the New York Central Railroad (Saint Lawrence and Ontario divisions), about 80 miles northwest of Utica and 73 miles north of Syracuse.

**Industries.** The city lies on both sides of the river, which has a fall of 112 feet inside

the city limits. From Carthage, a village 16 miles above the city, to Dexter, eight miles below the city, the river is lined with busy manufacturing villages, all of which contribute to a considerable extent to the prosperity of Watertown. Along this 24 miles of river valley the investment in paper mills alone exceeds \$15,000,000. More than 2,200 persons are engaged in the paper industry. Watertown in addition to its paper mills has a widely-diversified manufacturing life, the largest industry being the New York Air Brake Company, with nearly 3,000 persons regularly employed in the production of air-brake equipment. Other large manufacturing establishments include the Kops Brothers' corset factory, one of the largest in the country. The Bagley and Sewall Company, producers of paper and pulp mill machinery and vises and J. B. Wise, Inc., operating a large brass rolling mill and foundry and producing a complete line of bathroom fixtures and plumbers' supplies. Two large flouring mills, one of which manufactures health and dietetic foods that are consumed throughout the United States and in many foreign markets; two silk mills, a glove factory, a plant producing clinical thermometers, a large knit underwear mill, several machine shops producing special machinery, wood-working plants and printing establishments are included in the list of manufacturing institutions of Watertown. Over 8,000 employees are engaged in the operation of these industries, which have gross annual products of more than \$20,000,000.

**Trade and Finance.**—Watertown is the financial and commercial centre of a rich agricultural region and is the trading town for the people of the rural section and the numerous communities within a radius of 35 miles. The county of which Watertown is the seat is one of the largest in the United States in the number of dairy cows and in the production of hay and forage crops. The Watertown Produce Exchange, made up of the manufacturers of American cheese, is the largest inland cheese board in the world. The annual sales of this commodity on the local exchange exceed \$2,500,000. Watertown has one trust company, three national banks, two savings banks and a large building, savings and loan association. The trust company and national banks have deposits in excess of \$15,000,000; the savings banks, deposits of more than \$13,000,000.

**Buildings and Municipal Improvements.**—The retail business of the city is located in Public square, an imposing plaza situated in the geographical centre of the community. In recent years, as a result of continued increase in population, retailing interests have invaded six of the thoroughfares that radiate from the common centre. The public buildings include the government post office, a State armory, four county buildings, the city hall and the Roswell P. Flower Memorial Library, a classic marble structure costing nearly \$300,000—the gift to the city of Mrs. Emma Flower Taylor, as a memorial to her father, who was a governor of the State of New York. The city also has two orphanages, three hospitals, the City Hospital and Saint Joachim's, the latter being conducted by the Sisters of Mercy. The Henry Keep Home, established and endowed by Mrs. Emma Keep Schley, is a refuge for the

aged The new Kamargo Hotel, a modern fireproof structure, cost \$550,000. The public schools, 11 graded and one high school, are not surpassed by any in the State of New York. A full-paid fire department, housed in four modern buildings and equipped with motor-driven apparatus, is a model of efficiency. The city has 23 churches, the largest and most attractive being Trinity Episcopal, erected by the late Roswell P. Flower and his brother, the late Anson R. Flower; the Sacred Heart and Holy Family (Catholic), the Emmanuel Congregational and the Asbury Methodist. The Young Men's Christian Association, with a modern six-story building containing gymnasium, swimming pool, bowling alleys and other accessories and equipment, occupies one of the most valuable sites in Public square. The Young Women's Christian Association, occupying its own building, which is also located in Public square, is another important institution in the religious life of the city. The Black River Valley Club, with a modern clubhouse in lower Washington street; the Elks' Club; the Masonic Club, housed in a beautiful marble temple; the Knights of Columbus, with a spacious club home in Stone street, close to the business centre, and the Lincoln League, with 2,000 members, are the principal social organizations of the city. Watertown is overlooked on the east and south by a beautiful public park, purchased, developed and presented to the city by an unknown donor. It embraces more than 600 acres, a considerable portion of which has been improved with drives, walks, storm water sewers, its own water-supply system and a most attractive landscape scheme, with shrubs and flowering plants in great profusion. Two daily and one weekly newspapers are published in the city.

**Government.**—On 1 Jan. 1920 the city of Watertown went under the commission-manager plan of municipal government. Pop. 26,895.

FRANCIS H. LAMON,  
*Secretary, Watertown Chamber of Commerce.*

**WATERTOWN, S. D.**, city, county-seat of Codington County, on the Big Sioux River, and on the Chicago and Northwestern, the Minneapolis and Saint Louis, Chicago, Rock Island and Pacific, and the Great Northern Railway, with branch lines, about 100 miles north by west of Sioux Falls.

It is in a fertile agricultural region, elevation 1,750 feet, in which the chief products are wheat, rye, flax, barley, corn, potatoes and sugar beets; stock raising is also given considerable attention. The city has flour mills, machine shops, foundries, large grain elevators, meat packing house and stock yards; besides a tow mill; sash and door, farm implement and tractor and wagon factories. It has an extensive trade in grain and livestock; and is a large distributing centre for agricultural implements, automobiles, groceries, fruits and produce. There are 10 churches, a public high school, six graded elementary schools, a Carnegie public library and the Barton and Luther hospitals. There are five national and State banks, and five newspapers, two of which are issued daily. The city government from 1913-15 under commission form returned to the aldermanic form in 1916. The city owns water

and light and power plants. About three miles from the city is Lake Kampeska, one of the most beautiful bodies of water in the State, a favorite summer resort, with casino, club houses, municipal golf links and parks. Watertown was founded in 1881 and incorporated 26 March 1885. Pop. 12,000.

**WATERTOWN, Wis.**, city in Jefferson and Dodge counties on the Rocke River, and on the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads, about 44 miles west of Milwaukee and 38 miles east of Madison, the capital of the State. It is on both sides of the river, and has considerable water power which is utilized by various manufacturing plants, chief of which are two large shoe factories, flour mills, a foundry, machine shops, a brewery; cigar, box, furniture, paper box, tractor and money changing device factories and creameries. Watertown has several educational institutions, chief of which are the College of Our Lady of the Sacred Heart (Roman Catholic), the Northwestern College (Lutheran), a high school and a free public library. The four banks carry deposits of over \$3,200,000 and one of the three newspapers is a daily. The government is vested in a mayor and a council of 14 members, elected biennially. Watertown was first settled by Timothy Johnson in 1836, and was incorporated in 1837. In 1853 it was chartered as a city. Pop. 9,282.

**WATERVILLE, Me.**, city in Kennebec County, on the Kennebec River, and on the Maine Central Railroad, about 17 miles north by east of Augusta and 78 miles northeast of Portland. It was settled about 1760 by emigrants from Cape Cod, and was part of Winslow until 1802, when it was set off as a town and incorporated. In 1873 West Waterville was set off from Waterville, and in 1888 the city charter was granted. Waterville, Fairfield and Oakland electric railways connect the city with all the nearby places. The Ticonic Falls furnishes a great water power used by the manufacturing factories. The chief industrial establishments are the cotton mills, which have 1,500 employees; railroad shops, 350 employees; woolen factories, 500; paper and pulp mills, machine shops, etc. There are nine churches, Colby College (Baptist), founded in 1818; Coburn Classical Institute, Ursuline Academy (R.C.), a public high school, public and parish elementary schools and school libraries. There are four banks and one newspaper, a daily, and an up-to-date chamber of commerce with 325 members and a paid secretary-manager. The government is vested in a mayor, seven aldermen and 14 councilmen, elected annually. There are a number of French Canadians, but the majority of the inhabitants are native born. Pop. 12,501.

**WATERVILLE, N. Y.**, village in Oneida County, on the Lackawanna Railroad, about 22 miles southwest of Utica. It is in an agricultural region in which hops and vegetables are the chief products. It has steam grist mills, a wood-working and a shoe factory. The principal public buildings are the Granger and Masonic halls, the Young Men's Christian Association building, and the churches and schools. There are six churches, a high school established in 1872, public graded schools and a

public library. There are two banks. Pop. about 1,410.

**WATERVLIET**, wā-tēr-vlēt', N. Y., city in Albany County, on the Hudson River and on the Delaware and Hudson Railroad, opposite Troy and six miles north of Albany. Electric railways connect the city with Albany, Troy, Schenectady and Cohoes. A steel bridge over which pass electric cars for both passengers and freight spans the river at this point. It is at the head of river navigation and has by means of the Hudson River water connections with New York and intermediate points. Watervliet is a factory city having plants making woolen goods, shirtwaists, collars, bells, iron products, sashes, doors and blinds, metal harness parts, street cars, car-journal bearings, machine-shop products and boats. In 1807 the United States government established here the Watervliet Arsenal for the construction of siege ordnance and field and coast defenses; in 1919 negotiations were opened for the purchase of some 35 acres of land comprising many city blocks, the plan being to enlarge the original reservation of 109 acres with its wharfage of 1,000 feet, and to make the plant the largest of its kind in the country. The construction works have been constantly in operation and some of the largest guns in the United States' service have been made here. The place was the scene of great activity during the World War; at an expenditure of between 12 and 14 million dollars the normal output was tripled, the maximum number of employees reaching 5,125. Within the arsenal reservation are quarters for officers and barracks for soldiers. There is also a large stone magazine. The city has 12 churches representing six denominations; a high school established in 1899, Saint Patrick's Academy and public and parish schools. There is a graded school in connection with Saint Colman's Orphanage, and also with Fairview Home. Watervliet was settled about the time the first settlements were made at Albany and other places on the Hudson. It was incorporated as a village, and called West Troy in 1836. In August 1897 it was chartered as a city under its present name. Its industrial growth has been closely connected with the work of the government arsenal. It has many of the social and educational advantages of Troy and Albany. The waterworks are owned by the city, and on 10 June 1919 the commission form of government was adopted. Pop. about 18,000.

**WATERWAYS OF THE UNITED STATES**, The. The atlas of the world shows that three-fourths of its surface is covered with water. The waters of the earth comprise oceans, seas, straits, gulfs, bays, lakes and rivers. In the main these are navigable, but where not navigable, much has been done to make them so. In addition thereto, extensive systems of intersecting canals have been constructed, so that natural and artificial waters of the world, known as "waterways," comprise all its oceans, seas, gulfs, sounds, bays, many of its lakes and rivers, and all navigable canals.

In the United States the ebb and flow of the tide is not the test of navigability as it was in England before it was abolished by 24 Vict., ch. 10. The Supreme Court of the United States held in the *Daniel Ball*, 10 Wall.

557, that a different test than tidal variations must be applied here to determine navigability. The courts say that those rivers must be regarded as public navigable rivers in law, which are navigable in fact; and they are navigable in fact when they are used, or are susceptible of being used, in their ordinary condition, as highways for commerce, over which trade and travel are or may be conducted in the customary modes of trade and travel on water. The commercial power of Congress authorizes such legislation as will insure the convenient and safe navigation of all navigable waters of the United States, whether that consists in requiring the removal of obstructions to their use, in prescribing the form and size of the vessels employed upon them, or in subjecting the vessels to inspection and license. The power to regulate commerce comprehends the control for that purpose and to the extent necessary, of all navigable waters of the United States which are accessible from a State other than those in which they lie. For this purpose they are the public property of the nation, and subject to all the requisite legislation of Congress. In the case of *Perry v. Haines*, 191 U. S. 17, the same court decided that admiralty jurisdiction extends to cases of maritime liens upon vessels navigating the Erie Canal, as that formed part of a navigable highway for interstate commerce between Lake Erie and the ocean. Thus artificial as well as natural navigable waters are being recognized as public waters in the sense in which Bracton used that term in the rule that *publica vero sunt omnia flumina et portus*. Years ago the English courts decided that the river Severn was a public highway, and the courts of the United States have followed the decisions of the Supreme Court of the United States heretofore stated in regard to public navigable waterways. An interior nation has a servitude along natural watercourses to reach the highway of nations, known as *ius transitus*, which is recognized by the law of nations. The right of transit over the Danube below the Iron Gates is secured by agreement. In the United States and in Canada, the rivers do not generally flow in foreign territory, so that it is not necessary to invoke the doctrine of *ius transitus*, except in a few cases, as along the Richelieu and lower Saint Lawrence.

**The Atlantic Coast. Maine.**—The waterways of Maine include 240 miles of seacoast, with many bays indenting it and scores of islands strewn along it. The Saint Croix River on the east is the outlet of Grand Lakes. It forms part of the international boundary and is navigable from its mouth up to Calais. Its tonnage in 1917 was 61,896 tons. The Penobscot is 275 miles long and navigable to Bangor by large vessels. It is the outlet of several lakes in central Maine and flows into Penobscot Bay, 30 miles long and 15 miles wide. Its tonnage in 1917 was 340,198 tons. The Kennebec is 160 miles long and navigable to Augusta. It is the outlet of Moosehead Lake, which is 36 miles long and from 8 to 12 miles wide, and navigated by pleasure steamers.

The Kennebec has a channel 150 feet wide and from 18 to 16 feet deep up to Gardiner and thence a channel 125 feet wide and 11 feet deep up to Augusta. The tonnage on that river in 1917 was 123,855 tons. The Androscoggin

River drains the famous Rangeley lakes and other lakes, and flows 200 miles into the Kennebec near its mouth. It is navigable only in part and by river craft. Sebago Lake is 12 miles long and 10 miles wide and navigable by small steamers.

Its principal seaport is Portland, but it also has other improved harbors, among which are Bar Harbor, Stockton, Camden, Rockport, Rockland, Matinicus, South Bristol, Boothbay, Sasanoa and others.

Portland has a developed waterfront of four miles in extent. It has 47 wharves, 12 of which are used for transportation terminals. Its tonnage in 1917 was 2,905,428 tons.

The tonnage of Bar Harbor in 1917 was 27,723 tons.

Saco River, 105 miles long, has a channel seven feet deep and from 100 to 200 feet in width for six miles up-stream. In 1917 its tonnage was 53,216 tons.

*New Hampshire and Massachusetts.*—New Hampshire has Portsmouth as its principal fortified harbor. Its rivers are few. Cochemo and Exeter rivers are navigable a few miles for light draft vessels and the channel of the Merrimac has been improved to Haverhill, 16½ miles, to a depth of seven feet. Fourteen wharves extend along the Merrimac. Its tonnage in 1917 was 18,031 tons. Portsmouth and other harbors have been improved.

Pepperells Cove is a part of Portsmouth Harbor and has been improved for anchorage purposes, the controlling depth being 11 feet. Its tonnage in 1917 was 109,781 tons.

The inland lakes of New Hampshire are navigable by small pleasure boats. The same is true of the rivers of Massachusetts. It has, however, Boston Harbor, Massachusetts Bay, Cape Cod Bay, which is connected with Buzzard's Bay by a canal across Cape Cod, Nantucket Sound, Vineyard Sound, Buzzard's Bay and several other small bays, all in communication with the ocean. Boston has a land-locked harbor of 47 square miles in area. It has several improved channels from 23 to 40 feet deep and from 100 to 1,200 feet wide. Its inflowing tributaries, Chelsea Creek, Fort Point Channel, Charles River and Mystic River have all been made navigable. In 1917 the tonnage on Chelsea Creek was 532,200 tons; on Fort Point Channel 1,116,204 tons; on Mystic River 5,082,250 tons. It has four or more miles of fully-developed waterfront with wharves of various types devoted to ocean commerce. Gloucester, Beverly, Salem and Lynn harbors have all been improved. In 1917 the tonnage of Gloucester Harbor was 239,272 tons; of Beverly Harbor, 44,695 tons; of Salem, 58,158 tons and of Lynn Harbor, 338,783 tons.

Taunton River is navigable to Taunton, 15 miles from its outlet, which empties into Mount Hope Bay. The Malden, Weymouth Fore and Weymouth Back rivers are navigable at their mouths only. Salem, as a commercial port, has a reputation far more enviable than that for witchcraft.

*Vermont.*—Vermont has part of Lake Memphremagog, which is navigable by lake steamers, and part of Lake Champlain, 120 miles long and 15 miles wide in its extreme width, which has been, since its discovery on 4 July 1609, a highway of commerce for the aborigines, for

the colonists and for Americans generally. It is navigated by large lake steamers, by scores of other steamers and by many yachts and sailing vessels. It is one of the most picturesque lakes in America and forms an important portion of the 467 miles of waterway between the Saint Lawrence on the north and New York Bay on the south. It contains several beautiful islands, such as Isle La Motte, North Hero and South Hero. Lake Champlain is connected with the waters of the Hudson River at Fort Edward by the Champlain Barge Canal, having a depth of 12 feet of water, so that vessels drawing 11 feet may pass from Lake Champlain through into the Hudson River.

Whitehall, Port Henry, Burlington, Plattsburgh and Rouses Point are the principal improved ports of Lake Champlain. Its principal tributaries are the historic Otter Creek, where Commodore Macdonough built his fleet in 1814, the Missisquoi River and the Champlain or Big Chazy River. Its outlet is the Richelieu River, a tributary of the Saint Lawrence.

*Rhode Island.*—Rhode Island has Narragansett Bay, Mount Hope Bay, Providence and Seekonk rivers. These are navigable by large passenger and other vessels. Narragansett Bay, about 20 miles long and 12 miles wide, has channels through it to Providence and Fall River. Along its eastern margin is Sakonnet River with Portsmouth Harbor at the head of it. The Pawtucket River, 50 miles long, is improved in its lower section for a distance of five and two-tenths miles. Its tonnage in 1917 was 490,594 tons. Providence River and Harbor has been dredged to a depth of 30 feet over an area one and six-tenths miles in length and one-quarter mile in width. Its tonnage in 1917 was 3,406,224 tons. Fall River Harbor, at the mouth of Taunton River, has a channel 300 feet wide and 25 feet deep, extending out to Narragansett Bay. The steamers of the Fall River Line enter that harbor. In 1917 its tonnage was 1,469,750 tons. Newport Harbor, R. I., is an improved waterway with a channel 750 feet wide and 18 feet deep at low water. Its tonnage in 1917 was 204,701 tons.

*Connecticut.*—Connecticut has part of Long Island Sound, the Thames River, navigable to Norwich, the Connecticut River, the Naugatuck River, navigable by small craft for a few miles and the Housatonic, 150 miles long and navigable to Shelton. It has several towns along its waterways, such as Stonington, Norwich, New London, New Haven and Bridgeport.

The tonnage of the Connecticut River below Hartford in 1917 was 602,008 tons. That river has been improved as far as Holyoke, a distance of 85.9 miles from its mouth.

There are numerous harbors along the north shore of Long Island Sound with inflowing tributaries, many of which have been improved sufficiently to be navigable by coastwise vessels.

New London has an entrance channel 600 feet wide and 33 feet deep and is well equipped with wharves and other terminal facilities. In 1917 its tonnage was 690,977 tons.

The channel at New Haven is 400 feet wide and 20 feet deep, three miles up from Long Island Sound, and it has been somewhat extended at lesser depths and widths up-stream. In 1917 the tonnage at that port was 1,868,649

tons. Thames River, Connecticut, is a tidal estuary from 400 to 4,000 feet wide, extending from Long Island Sound to Norwich, a distance of 15 miles. Its channel is 200 feet wide and from 20 feet deep to Allyn Point and 14 feet deep from there to Norwich, with wharves at New London and Norwich. The tonnage on that river in 1917 was 328,188 tons. The Housatonic River has an improved channel from 100 to 200 feet wide and seven feet deep to Derby and Shelton, a distance of 13 miles from its outlet. Its tonnage in 1917 was 300,047 tons.

Bridgeport has several improved channels from Long Island Sound leading up to the port to accommodate coastwise vessels. Its tonnage in 1917 was 1,588,056 tons.

There are several other harbors along the south coast of Connecticut that have been improved, all of which show the increasing interest in waterways improvement.

Long Island Sound is 75 miles long and 20 miles wide. It is a great waterway for several superb steamboat lines plying between New York and towns and cities on its northern shore. The Connecticut River at one time was navigated by a number of river boats and had considerable commerce. A line of boats ran between Wells River, Vt., and Hartford. The boats were flat boats and did not draw much water. The *Barnet* was the first steamer for Connecticut River service. It drew 22 inches of water. On its first trip from Hartford to Vermont it had in tow a barge filled with people. Other steamers were built for river service, in which they were engaged for many years. This river was a great natural highway for the transportation of produce to market. The rapids in the river were overcome by canals at South Hadley Falls, at Turner Falls and at Bellows Falls.

*New York.*—The waterways of New York comprise that portion of the Atlantic Ocean washing Long Island on the south, and that part of Long Island Sound washing Long Island on the north, and also the upper and lower New York and Jamaica bays, and a portion of Staten Island Sound and all of the East, Harlem and Hudson rivers. They also include the Mohawk, Seneca, Chemung, Black, Oswego and parts of the Delaware, Susquehanna, Genesee, Allegheny, Niagara, Saint Lawrence and other rivers, interior lakes and parts of Lakes Erie, Ontario and Champlain and others.

In and about the port of New York are many inflowing streams and contiguous harbors. Some of these are Port Chester, Mamaroneck, Echo Bay, Westchester, Bronx River, Flushing Bay, Hempstead, Huntington, Port Jefferson, Mattituck, Great South Bay, Brown's Creek, Jamaica Bay, Sheepshead Bay, East River, Wallabout Channel, Newtown Creek, Harlem River, Hudson River, New York Bay and the various improved channels therein. All such waterways have been improved and are navigable by coastwise vessels, and many of them by the ocean-going vessels.

New York is the largest commercial port in the world, having wrested first place from London recently. The total tonnage of the port of New York for the year 1917 was 65,176,983 short tons. That was during the World War, when war supplies were being shipped in great quantities. Its unique position at the conflu-

ence of the East and Hudson rivers overlooking one of the finest harbors in the world, has added to its other commercial advantages and is destined to continue it as the emporium of the western hemisphere. On the north flows the picturesque Hudson, discovered in September 1609, and navigable by steam vessels 150 miles to the city of Troy, and by canal barges to Waterford. It has been improved, its many harbors also improved and the river has been canalized from Waterford to Fort Edward. It receives on the west the waters of the Mohawk, formerly navigable about 95 miles, to Little Falls, which is also canalized from the Hudson nearly to the city of Rome. The canalized Hudson and Mohawk form a part of the improved canal system of the State of New York, constructed pursuant to the provisions of the Canal Referendum Law, which law provided for the issue and sale of the bonds of the State, amounting to \$101,000,000, for the construction of a system of barge canals, having a bottom width of 75 feet and a depth of 12 feet, from the waters of the Hudson to those of Lake Champlain, Lake Ontario and Lake Erie, adequate for barges carrying 2,000 or more tons. That was followed by the Cayuga and Seneca canal referendum of 1909, authorizing a bond issue of \$7,000,000 to improve the Cayuga and Seneca Canal, which was approved. That was also followed by the Barge Canal Terminal referendum measure of 1911, authorizing a further bond issue of \$19,800,000 to construct Barge Canal terminals and was approved, and that was followed by the canal referendum of 1915, authorizing a further bond issue of \$27,000,000, thus making aggregate bond issues for canals and terminals of \$154,800,000. An additional bond issue of \$25,000,000 will be required to complete the system.

The Cayuga and Seneca Canal has been enlarged to Barge Canal dimensions and connects Cayuga and Seneca lakes with the Erie Barge Canal. The New York Barge canals have standard locks 328 feet long, 45 feet wide with 12 feet of water over mitre sills. These will admit of the passage of barges carrying 2,000 or more tons. See **BARGE CANAL**.

These are the largest canal improvement projects ever undertaken by one of the American States. West of the city of Rome is Oneida Lake, into which flows Wood Creek, which is canalized and connected with the Mohawk. Oneida Lake, Oneida River and Oswego River are all canalized, as well as the Seneca River from the Three River point to the outlet of Onondaga Lake, and thence southwesterly nearly to Seneca Lake. New York contains several beautiful bodies of water, such as Lake George, part of Lake Champlain, part of Lake Ontario, part of Lake Erie, Onondaga, Skaneateles, Cayuga, Seneca, Keuka, Canandaigua and Chautauqua lakes. All of these lakes are navigated by passenger steamers during the summer.

*New Jersey.*—The waterways of New Jersey comprise a portion of the lower Hudson, upper New York Bay, Newark Bay, Staten Island Sound, Raritan Bay, the Atlantic Ocean and several arms of the ocean indenting the eastern coast of New Jersey, and Delaware Bay on the south and the Delaware River on the west, and other rivers intersecting it.

*New Jersey and Pennsylvania.*—Newark Bay is navigable for six miles and Passaic

## WATERWAYS

1 New York State Barge Canal lock and dam in the canalized Hudson river. Look on the farther bank. Tainter gate regulating section of the dam in the foreground  
2 Dam at the foot of Mohawk river navigation — 1,922 feet long, of gravity type, with circular trace of 700 feet radius  
3 Lockport locks, where the Barge canal descends the Niagara escarpment. Two new locks have replaced one bar of five old locks

## WATERWAYS

1 Steel barges built for Federal Governmental use on the New York State Barge Canal and put in service in 1919  
2 Fleet of concrete barges on Barge Canal built and used by Federal Government

River in New Jersey for 16 miles. Hackensack River has been made navigable for 15 miles from its mouth. Staten Island Sound, 17 miles long, connects New York and Raritan bays.

Commerce on Raritan Bay, Arthur Kill and Passaic River in 1906 amounted to 25,584,273 tons.

The Raritan Bay, seven miles long, and Raritan River to New Brunswick, a distance of 12 miles, are being improved. The Raritan River is navigable from Raritan Bay to New Brunswick, and from that point along the bed of the Raritan and Millstone rivers to Trenton is a canal, thus joining the waters of Lower New York Bay with those of the Delaware. The total length of the Susquehanna River, including tributaries, is over 400 miles, and it is only partially navigable.

In some portions of its course the Susquehanna has been canalized to overcome rocks and vegetable matter, which obstructed its navigation. It flows into the Chesapeake Bay, which is 120 miles long and 50 miles wide. It has been improved to a depth of 15 feet with a width of 200 feet from Chesapeake Bay to Havre de Grace. It is proposed to render it navigable to Harrisburg. A bill authorizing an appropriation for this work was passed in 1919.

Pennsylvania has suffered its extensive canal system to pass from its control.

The Schuylkill River is being improved for six and one-half miles up from the Delaware River to a depth of 22 feet and 200 feet wide.

Delaware River is about 315 miles long and empties into Delaware Bay, which is 50 miles long. The river has been improved as far as Trenton, N. J., to a depth of 12 feet and to a width of 200 feet which is to be increased to 400 feet. Its channel from Delaware Bay to Philadelphia is 35 feet deep at low water and has a width of 800 feet, and in the city of Philadelphia it is 1,000 to 1,200 feet wide. The tonnage at Trenton in 1917 was 2,439,044 tons.

Philadelphia has extensive modern terminal facilities and its water-borne tonnage, coastwise and foreign, for the year 1917 was 26,282,734 short tons. The total arrival of vessels for the year was 51,206 and the departures were 58,838. This shows the enormous waterway activities of that port. Other ocean ports were more or less active.

*Middle Atlantic States.*—Wilmington Harbor on the Delaware River, at the mouth of Christiana River, includes sections of those two rivers and is well provided with wharves and terminals. Its tonnage in 1917 was 414,987 tons.

Several rivers, creeks and harbors in New Jersey, Delaware and Maryland have been improved. The Wilmington district includes 26 rivers, creeks and harbors that are being improved, the largest being Wilmington Harbor, including the Christiana River, navigable for 15 miles, and a tidal canal between Rehoboth and Delaware bays.

The Appoquinemink, the Smyrna, the Leipsic, Little Saint Johns, Murderkill, Mispillion and Broadkill rivers, all in Delaware, are small streams that have been improved in their lower reaches. A waterway six feet deep and 50 feet wide extends from Rehoboth Bay and Delaware Bay whose tonnage in 1917 was 15,275 tons.

The inland waterway from Delaware Bay to Chincoteague Bay, Virginia, which is six feet

deep and 70 feet wide, had a tonnage in 1917 of 22,520 tons.

The Chesapeake and Delaware Canal has been purchased by the United States government and is to be enlarged and made a sea-level canal, 12 feet deep at mean low water with 90 feet bottom width. It extends from the Delaware River to Black Creek at Elk River, a distance of 18.9 miles and becomes a part of the Intercoastal Waterway from Maine to Key West.

The Baltimore district includes 26 rivers and harbors undergoing improvement. The principal harbor is Baltimore. That includes Curtis Bay and Patapsco River and tributaries and is 11 miles above Chesapeake Bay. It has several channels of 35-foot depth and of variable widths from 400 to 1,000 feet with wharves, terminal facilities and a belt line railway connecting the waterfront terminals with the trunk line railways. Its tonnage in 1917 was 14,055,885 tons.

The Washington district comprises 11 rivers and harbors, including a part of the Chesapeake Bay and the streams emptying into it.

The harbor of Washington is on the Potomac River, 110 miles from its outlet into Chesapeake Bay. The average depth of water in its channel is 20 feet.

The Washington Harbor is two miles in length and 950 feet in width. It has 44 wharves, eight of which are municipal and eight are open to the public on equal terms. Vessels of 30 feet draft may moor at the docks extending 11,000 feet along the waterfront. In 1917, the tonnage was 837,221 tons. Above Washington is the Chesapeake and Ohio Canal of six feet depth of prism paralleling the Potomac for 175 miles to Cumberland, Md.

In 1906 its tonnage was 225,142 tons. The Anacosta River is 20 miles long, flowing into the Potomac at Washington. It has been improved and has 15 terminals. Its tonnage in 1917 was 226,911 tons. Several ports have been improved on the Potomac, such as Georgetown, Alexandria and Lower Cedar Point. The Potomac River is about 400 miles long and navigable 110 miles for large vessels. It flows into Chesapeake Bay from the northwest. It receives from the south the waters of the Shenandoah. The Rappahannock River is over 200 miles long and navigable by vessels of 10-foot draft to Fredericksburg, a distance of 110 miles.

The James River is 320 miles long and is being improved to Richmond, a distance of 103.8 miles. Its channel will be 22 feet deep at mean low water and have a width of 200 to 400 feet. The river is equipped with terminals at various points connecting with railroads. It has extensive wharves and docks at Richmond, some of which are free for public use. In 1917 the tonnage was 715,255 tons.

Norfolk Harbor, Va., has a channel 40 feet deep at mean low water and 750 feet wide from Hampton Roads to the mouth of the southern branch of the Elizabeth River, and thence 450 feet wide up that branch, a distance of 11¾ miles, except in front of the navy yard where the channel is 35 feet and from 600 to 800 feet wide. There are other channels in the harbor of various dimensions. Its wharves, piers and terminals number 165. In 1917 its tonnage was 31,870,321 tons.

The harbor at Newport News, 10 miles west of Norfolk, has a channel 600 feet wide, 35 feet draft and three and one-quarter miles long. It has extensive shipbuilding, railway and other facilities. Its tonnage in 1917 was 6,259,774 tons. The lower reaches of the Appomattox, 137 miles long, a tributary of the James River, are being improved to a depth of 12 feet and with a diversion channel two and one-half miles long, and from 200 to 400 feet wide below Petersburg. Its tonnage in 1917 was 335,947 tons. The Pagan and Nansemond rivers and Cape Charles City Harbor, Va., are being improved. The Congress of the United States has made appropriations in part for the construction of an intracoastal waterway with a prism having a bottom width of 90 to 300 feet and a depth of 12 feet at mean low water, paralleling the Atlantic Coast from Norfolk, Va., to Beaufort, N. C., a distance of 186 miles. It will comprise natural watercourses except through four land cuts to connect such watercourses.

The tidal waterway along the coast of Virginia, including Cat River and Bogue Bay, with a channel four feet deep and 25 feet wide, had a tonnage in 1917 of 109,024 tons.

Four routes were surveyed for that intracoastal canal and the route via the Albemarle and Chesapeake Canal was recommended. It follows the existing waterway, via Neuse River, Adams Creek, Adams Creek Canal, Core Creek and Newport River. Several rivers which flow into the Atlantic Ocean and into the bays connected by this intracoastal canal are being improved for some distance up from their outlets and wharves and terminal facilities are being installed along their navigable waters. Roanoke River is 198 miles long, and from Weldon to its mouth, a distance of 129 miles, it is being improved to secure a channel 50 feet in width and six feet in depth. In 1917 its commerce was 78,736 tons. The Roanoke flows into Albemarle Sound, which is about 50 miles long and from five to eight miles wide, and it communicates through Croatan Sound with Pamlico Sound, which is 75 miles long and about 20 miles wide. These sounds will be connected with the Chesapeake by the intracoastal canal, having a depth of 12 feet and destined to do an active business.

The Wilmington, N. C., district comprises 25 rivers and harbors, including Beaufort Harbor, N. C., and several inland waterways and Cape Fear River. Most of the sounds are shallow and communicate with the Atlantic Ocean. Into Pamlico Sound flows the Pamlico and the River Neuse. The Cape Fear, Black and East Cape Fear rivers have been improved. Most of the other rivers and harbors of the Wilmington, N. C., district will be improved and brought into navigable communication with the coastal canal.

*South Atlantic States.*—The Charleston, S. C., district includes 11 rivers and harbors. The Waccamaw River is to be improved its entire length of 147 miles. The Little Peedee, South Carolina, is to be improved 113 miles above its outlet into the Great Peedee River, so as to have a four-foot channel. The Santee River is to be improved and a canal constructed between Estherville and Minim Creek, six feet deep and 70 feet wide for river steamers. Wateree River is to have a four-foot navigable

channel from Camden to its mouth, a distance of 67 miles.

The Congaree River is to have a four-foot navigable channel for 49 miles above its mouth. The creeks, sounds, rivers and bays between Charleston Harbor and Alligator Creek for a distance of 47½ miles are being connected by a channel 100 feet wide and six feet deep at mean low water, and another channel seven feet deep has been recommended from Win-yah Bay to Charleston, via Estherville-Minim Creek Canal. Charleston Harbor has an area of six square miles and is to be improved by the construction of a channel 30 feet deep and 500 feet wide from the sea up to the navy yard, and 1,000 feet wide out to seaward. The North Jetty is 15,443 feet long and the South Jetty is 19,104 feet long and the passage-way between them is 2,900 feet wide. The eastern waterfront of Charleston Harbor has three-quarters of a mile of piers and the same length of marginal wharves. On the western front there is one small public wharf. The tonnage of the port in 1917 was 766,026 tons. The harbor is formed at the confluence of the Ashley and Cooper rivers. The Ashley River is being improved by constructing a channel 24 feet deep at mean low water and 300 feet wide from the mouth of the river up to the Standard wharf, a distance of seven and one-half miles and of eight feet depth above that to Lambs. Ashley River also has 12 phosphate wharves. Cooper River has been improved to a depth of 32 feet for six miles and a marginal wharf and warehouses have been built along it.

Savannah, Ga., district comprises 16 rivers and harbors. Savannah Harbor is being improved by a channel 30 feet deep and 500 feet wide to Quarantine, thence 26 feet deep and from 400 to 500 feet wide to the city waterworks, a distance of 16 miles, and thence 21 feet deep and 300 feet wide, one and one-half miles to King's Island, making the entire length of the improvement 27½ miles. The turning basin at West Broad and Barnard streets is 26 feet deep and 600 feet wide with a basin at Fort Oglethorpe 26 feet deep and 900 feet wide. It has a wharf frontage of five miles, comprising municipal, private and railway terminals. Its tonnage in 1917 was 2,429,288 tons. From Savannah, 17 miles from the sea to Augusta, 218 miles from the sea, the Savannah River has a navigable channel of five feet depth, and along its course on many landings and at Augusta are private wharves with a total frontage of 1,450 feet. It also has a municipal wharf and warehouse with an electrically equipped elevator and locomotive crane. From Augusta to Petersburg, a distance of 53 miles, a channel is being maintained from 12 to 25 feet wide for vessels with a draft of one and three-tenths feet. A waterway 53 miles long with a depth of seven feet is being constructed along Ramshorn Creek, Wright and Mud rivers from Savannah to Beaufort, S. C. Another waterway is being constructed from Beaufort, S. C., to Saint John's River, Florida. Still another project provides for a channel seven feet deep and 150 feet wide from Savannah, Ga., to Fernandina, Fla., through Skidway and Creighton Narrows, Little Mud River, Frederica and Jekyll creeks and Cumberland River, a distance of 147 miles. Auxiliary channels through Three Mile Cut, near Darien,

around Saint Simon's and Saint Andrew's Sound and along Club and Plantation Creek with supplemental routes, altogether measuring 183 miles. These improved natural channels made navigation safer and reduced freight rates. An improved waterway, 29 miles long, seven feet deep and 100 feet wide, connects Saint John's River, Florida, six miles from its mouth, with Cumberland Sound, Georgia. Other waterways and harbors in that region are being improved.

Satilla River, Georgia, 350 miles long, is being improved so as to afford steamboat navigation 93 miles up-stream. The channel of Saint Mary's River for 12½ miles above its mouth is 17 feet deep and 200 feet wide and for 24½ miles still further up-stream the channel is being cleared.

The Altamaha River is being improved its entire length of 137 miles. It will have a channel 60 to 100 feet wide and four feet deep. Its tonnage in 1917 was 37,625 tons. The River Oconee for 145 miles and Ocmulgee for 205 miles, whose confluence forms the Altamaha, are being improved in the same manner as the last-named river. The inner and outer harbors of Brunswick, Ga., are to be dredged to a depth of 30 feet at mean low water and equipped with terminal facilities. Fernandina Harbor, Florida, and Cumberland Sound, Georgia and Florida, are also being improved.

The Jacksonville, Fla., district includes 26 rivers and harbors undergoing improvement to various navigable depths.

Saint John's River is to have a channel from 300 to 600 feet wide and a depth of 24 to 30 feet from Jacksonville to the ocean, a distance of 28 miles, and a channel 200 feet wide and 13 feet deep from Jacksonville to Palatka, a distance of 55 miles, and a channel 100 feet wide and eight feet deep from Palatka to Sanford and five feet deep from Sanford to Lake Harney, the two last improvements extending up the river 115 miles above Palatka. Lake Crescent, 14 miles long and one to three miles wide, is in touch with Saint John's River through Dunn's Creek, eight and one-half miles long, with a channel 100 feet wide and eight feet deep.

In 1917, the total number of arrivals and departure of steamers, motor boats, sail boats, lighters and rafts on the Saint John's River was 10,098. The freight traffic was 174,609 tons. A waterway, known as the East Coast Canal, extends from Saint John's River to Key West, Fla.

The channel of the Oklamaha River, Florida, a tributary of Saint John's River, is being cleared to a depth of six feet from its mouth to Silver Springs Run, a distance of 62 miles. Indian River has a channel 75 feet wide and five feet deep for 77 miles; Lucie Inlet with a channel 200 feet wide and 18 feet deep connects Indian River with the ocean, 235 miles south of Saint John's River. The Miami Harbor has an entrance channel 300 feet wide and 20 feet deep. It embraces artificial basins and dredged channels through to the ocean with parallel projecting stone jetties. It has wharves and piers, some of which are public. Its water-borne tonnage in 1917 was 244,380 tons.

The harbor at Key West has a channel 300 feet wide and 30 feet deep. The channel oppo-

site the wharves is 26 feet deep and 800 feet wide. It is an important harbor affording shelter for vessels exposed to hurricanes. It had a tonnage in 1917 of 745,056 tons.

**Gulf Coast.**—The Kissimmee River is being cleared and is to have a channel 30 feet wide and three feet deep for 99½ miles, connecting several interior lakes, including Kissimmee, Tohopekaliga and Okeechobee, connected many years ago by canals with Lake Hicpochee. The lowering of the water in Lake Okeechobee for drainage purposes has interfered with the navigation of the upper Kissimmee River, which was navigable for 137 miles. The Caloosahatchee River has a channel 200 feet wide and 12 feet deep to Puntarasa and thence a channel 100 feet wide and 10 feet deep to Fort Myers, where there is a turning basin and a channel from two to four feet deep to Fort Thompson. Fort Myers is 20 miles from Charlotte Bay and Fort Thompson is 43 miles from Fort Myers. A drainage canal connects Fort Thompson through Lake Hicpochee with Lake Okeechobee. That is to be improved and made navigable so there will be a navigable channel through from Charlotte Harbor to Lake Tohopekaliga. The Orange River, a tributary of the Caloosahatchee, is also being dredged so as to have a navigable depth of four feet for a distance of six miles. Charlotte Harbor is from five to 11 miles wide and 11 miles long and is to have a channel 300 feet wide and 24 feet deep to Boca Grande, and 10 feet deep to Punta Gorda and six or seven feet in Pine Island Sound. There is now a channel 12 feet deep up Peace River to Punta Gorda, 200 feet wide in the bay and 120 feet wide in Peace River. In 1917 the tonnage was 304,095 tons.

Sarasota Bay is to be brought into navigable communication with Tampa Bay on the north by a proposed channel 100 feet wide and five feet deep. Little Sarasota Bay has a channel 75 feet wide and three feet deep to Venice. Tampa Bay is a large body of water 25 miles long to Gadsend Peninsula where it divides into Hillsboro Bay and Old Western Tampa Bay. It is from seven to ten miles wide. It has a channel from its entrance to Port Tampa 200 feet wide and 26 feet deep. Its tonnage in 1917 was 1,181,076 tons.

The connecting bays and inflowing rivers are being provided with navigable channels of 200, 300 and 500 feet in width. Hillsboro Bay and river and Manatee River are navigable for several miles. Saint Petersburg is on the west shore of Tampa Bay eight and three-quarters miles from Port Tampa. That part of the bay is called Bayboro Harbor connected by a channel 200 feet wide and 10 feet deep with the wide waters of Tampa Bay. Its tonnage in 1917 was 22,151 tons. Clearwater Harbor eight miles long and from one-half to one and three-quarters miles wide and Boca Ceiga Bay are shallow sounds but navigated by small vessels. The lower reaches of Anclote crystal, Withlococoochee and Suwannee rivers are navigable for small vessels. The latter has been improved up to Ellaville, 135 miles above its mouth, and has a channel 150 feet wide and five feet deep for the first 75 miles, and one 60 feet wide and four feet deep for the remaining 60 miles.

**Alabama.**—The Montgomery, Ala., district includes 18 rivers and harbors. Carra-

belle Harbor, Apalachicola Bay and river, the lower and upper Chipola, Flint and Chattahoochee rivers, the canal  $36\frac{1}{2}$  miles long connecting Apalachicola River, which is a large stream, and Saint Andrew's Bay and the entrance to Saint Joseph's Bay are all navigable waterways with channels of different widths and depths. They are being improved. Choctawhatchee Bay, 20 or more miles long, is navigable. Choctawhatchee River has a navigable channel from its mouth up to Geneva, Ala., a distance of 96 miles. Its tributary, the Holmes River, is to be made navigable from its mouth up to Vernon, a distance of 25 miles. Blackwater River will have a channel 100 feet wide and nine feet deep up to Milton, a distance of 10 miles. Escambia River,  $65\frac{1}{2}$  miles long in Florida, and Conecuh, 235 miles long in Alabama, is the same river and is to have a navigable channel from its mouth to Patsaliga Creek, a distance of 147 miles, unless the present project be modified.

Pensacola Harbor is 13 miles long and is five miles wide. It joins Escambia, East and Blackwater bays and Santo Rosa Sound on the southeast. Pensacola Harbor has a channel 500 feet wide from the Gulf of Mexico and 28 feet deep. It is equipped with several wharves, a terminal railway and warehouses. Its tonnage in 1917 was 524,058 tons. The Alabama River formed by the confluence of the Coosa and Tallapoosa rivers,  $22\frac{1}{2}$  miles above Montgomery, unites with the Tombigbee River, 44 miles above Mobile, to form the Mobile River. The Alabama, whose width is from 400 to 700 feet, and Coosa rivers are being improved so as to have a continuous channel four feet deep up to Wetumpka on the Coosa, a distance of 321.6 miles. Vessels of three feet draft may now navigate the river all the year as far as Montgomery where there are some terminal facilities and whose port tonnage in 1917 was 94,356 tons. The Coosa River, formed by the Oostanaula and Etowah rivers, is being improved by the construction of a channel 100 feet wide and four feet deep and of seven dams and seven locks 40 to 52 feet wide and 176 to 280 feet long at various points, rendering the river navigable for  $165\frac{1}{2}$  miles above its mouth,  $22\frac{1}{2}$  miles above Montgomery. Its tonnage in 1917 was 15,744 tons.

The Mobile, Ala., district includes 14 rivers and harbors. Into Mobile Harbor flows Mobile River. A channel 300 feet wide and 27 feet deep has been constructed from the ocean up Mobile Bay for  $33\frac{1}{2}$  miles to the river and thence up Mobile River in front of the city of Mobile for five miles to Chickasaw Creek. In the bay it is 200 feet wide and in the river 300 feet wide. Wharves and piers line the west shore of Mobile River for two and one-fourth miles. The city owns a wharf and pier in the upper end of the bay 8,300 feet long and 300 feet wide. Mobile tonnage in 1917 was 1,816,284 tons. Black Warrior River, a tributary of the Alabama River, has been dredged, and 17 dams and 18 locks have been constructed to afford slackwater navigation for  $332\frac{1}{2}$  miles from its mouth to Sanders Ferry on the Mulberry Fork of the Black Warrior River and to Nichols Shoals on the Locust Fork of the same river. The entire length of the section to be improved is  $443\frac{1}{2}$  miles to

Sanders Ferry and  $423\frac{1}{2}$  miles to Nichols Shoals. The channel is 100 feet wide and six feet deep. The locks are 52 feet wide, about 282 feet long with a depth of six and one-half feet of water over mitre sills. The tonnage on that part of the improved waterway in use in 1917 was 580,728 tons. The Tombigbee River is shallow, having a channel two feet in depth, though in some sections it is six feet deep and all the way 100 feet wide from Demopolis to its mouth, a distance of 185 miles. In 1917 the tonnage thereon was 445,458 tons. From Demopolis, Ala., to Columbus, 149 miles, which is 230 miles from its mouth, the Tombigbee is to have a channel six feet deep by dredging and by the construction of dams and locks. From Columbus to Walkers Bridge, 169 miles, it is to have a high-water channel, which is more or less hazardous.

*Mississippi and Louisiana.*—Pascagoula Harbor and Gulfport Harbor have both been improved, the former having a channel 300 decreasing to 153 feet in width and a depth of 25, decreasing to 22 feet in depth four miles up Dog River. It had a tonnage in 1917 of 199,817 tons and the latter (Gulfport Harbor) has a channel 26 feet deep and 300 feet wide made through Slip Island Pass and one 19 feet deep and 1,320 feet wide for an anchorage basin one-half mile long. It had a tonnage in 1917 of 345,688 tons. Both ports have limited terminal facilities. Leaf and Chickasahay rivers have been cleared of obstructions and are navigable, the former for low water navigation 78 miles above its mouth and the latter for rafts 75 miles above the outlet. Those two rivers unite to form the Pascagoula River flowing into Mississippi Sound. That river has a channel of seven feet depth from the mouth of Dog River to Dead Lake, 32 miles, and of three feet depth above that point for 50 miles. Biloxi Harbor, Saint Louis Bay, Wolf, Jordan, East Pearl, including Lake Borgne, and Pearl rivers near the Gulf of Mexico have been dredged and are navigable for vessels of small, but different draft for limited distances. Pearl River is to have a navigable depth of two feet from its mouth to Rockport, a distance of 246 miles.

The New Orleans district includes 25 rivers, harbors and lakes. These include the South and Southwest Passes up into the Mississippi River. The latter is 1,000 feet wide between bulkheads and in the ideal area 2,400 feet wide and 35 feet deep, completed for seven miles with protecting jetties, the east one four and one-half miles and the west three and one-half miles long. Through the South Pass the channel is at least 39 feet deep between parallel dikes 700 feet apart. It is 14 miles via the South Pass from the gulf to the head of passes, 91 miles below New Orleans. The improvement of the several mouths of the Mississippi is the work of years and has involved all the skill of the Engineers of the United States army. Dikes, submerged sills with mattresses placed on the sills at the head of Pass à Loure, through which 45.7 per cent of the waters of the river flow, and levees have been constructed at various places below New Orleans. The harbor at that city, which is about 104 miles from the Gulf, possesses the advantages of a seaport. It is from 1,500 to 3,000 feet wide

and 40 feet deep and has extensive wharves and other modern terminal facilities. It accommodates ocean-going vessels. Its domestic and foreign commerce in 1917 totaled 8,026,283 tons. Its river commerce is increasing.

Lake Pontchartrain, 40 miles long and 24 miles wide, has a central depth of 16 feet. The principal channel is seven feet deep except through the dredged channel of eight feet in depth to Lake Borgne, which is in navigable communication with Mississippi Sound. The new Basin Canal, seven miles long, brings it into communication with New Orleans. The channels of Chefuncte, which flows into the lake, and Bogue Falia, its tributary, 10½ miles above Lake Pontchartrain, are improved to Covington, a distance of 14½ miles. The tonnage of those waterways in 1917 was 288,630 tons. Pass Manchac, rising in Lake Maurepas and flowing into Lake Pontchartrain, seven miles long, is to have a channel seven feet deep and 100 feet wide and will pass vessels plying the Amite River, Bayou Manchac and Tickfaw River to and from New Orleans.

Tickfaw River flows into Lake Maurepas. It receives the Natalbany River two miles above its mouth and the Blood River seven miles above its mouth. Its channel is dredged to seven feet for 10 miles and to six feet from the 10th to the 26th mile above its mouth. Blood River is to be similarly dredged for four miles and Natalbany River and its tributary Ponchatoula, together, are improved for 15½ miles. The Amite River is to be cleared of obstructions for 110 miles above its mouth and its channel deepened and widened for 44 miles. Bayou Manchac is to be improved for 11½ miles above its mouth. Other bayous in Louisiana are being improved. An intercoastal waterway of five feet depth and of 40 feet wide on the bottom is being constructed from Bayou Teche near Franklin to the Mermenteau River, a distance of 45 miles. It extends through several lakes and through the Hanson Canal, purchased by the United States, for a distance of 4.2 miles. A dam across Schooner Bayou and a lock are to be constructed. It also includes Schooner Bayou Canal 12 miles long, crosses White Lake 13½ miles and includes the canals, connecting Turtle, Alligator and Collicon lakes and extends to Grand Lake 12 miles wide. That waterway is navigable throughout the year. Another connecting intercoastal waterway extends from Mermenteau River, Louisiana, to Sabine River, a distance of 62 miles. It includes the Lake Misere Canal and passes south of Sweet Lake and then to Calcasieu River. It has a prism five feet deep and 40 feet wide and is to be seven feet deep and 75 feet wide from Mermenteau to Calcasieu River. It is open throughout the year. Bayou Lafourche, once one of the outlets of the Mississippi, has a lock at its head and a channel five feet deep and a bottom width of 75 feet through its entire length of 107 miles. Its tonnage in 1917 was 766,203 tons. Bayou Terrebonne is 53 miles long and empties into a bay of the same name. It has a channel six feet deep from its mouth to Houma, a distance of 24.11 miles. In 1917 its tonnage was 188,411 tons. Bayou Plaquemine is 112 miles from New Orleans via Mississippi, with which river it is connected by Plaquemine lock. Ves-

sels passing through that lock in 1917 varied in draft from three and one-half to seven feet and the tonnage was 205,741 tons. It forms 10.6 miles of the waterway to Morgan City, La. That waterway also includes 19.4 miles of the Grand River, Bayou Natchez for six miles, Little and Big Goddel for six miles, Belle River for nine miles, Bayou Long for seven and three-tenths miles, Flat Lake and Drews Pass to Berwick Bay three and two-tenths miles and thence by Atchafalaya River three and two-tenths miles to Morgan City. Pigeon bayou connects Grand River with Grand Lake. The entire waterway is 64 miles long. The lock is 298 feet 7 inches long and 55 feet wide with 10 feet of water over the mitre sills. The tonnage over that waterway in 1917 was 776,781 tons. The boats were of four to seven feet draft. Bayou Grossetete, a tributary of the Bayou Plaquemine, is being improved from its mouth eight miles below Plaquemine lock to above Maringouin, La., a distance of 29 miles. It will have a channel five feet deep and 60 feet wide. Its tonnage in 1917 was 237,947 tons. Bayou Teche is 125 miles long and joins the Atchafalaya River 10½ miles above Morgan City. It is to have a channel six feet deep and 50 feet wide from its mouth to Arnaudville, La., a distance of 106½ miles. It is to have a dam and lock at Keystone Plantation 72½ miles above its mouth and other regulating works. In 1917 its tonnage was 693,622 tons, but that passing Keystone lock was only 10,172 tons. The Atchafalaya River, an outlet of both the Mississippi and the Red River, was provided with a channel from a point 17½ miles below Morgan City to its mouth in Atchafalaya Bay, from 1,500 to 3,000 feet in width and from 20 to 140 feet in depth. The last improvement was from the 20-foot contour four miles below its mouth to the 20-foot contour in the Gulf of Mexico, a distance of 15¾ miles to give it a ship channel 20 feet deep and 200 feet wide. The channel from Morgan City down will have a minimum depth of 14 feet and a width of 200 feet. The tonnage at Morgan City in 1917 was 814,713 tons and was carried in vessels of not exceeding 11 feet draft. Vermillion River is to have a channel five feet in depth and 40 feet on the bottom from Vermillion Bay to Lafayette, La., a distance of 51 miles. Its tonnage in 1917 was 32,810 tons. Mermenteau River is 71½ miles long and is being improved its entire length and through Lake Arthur six miles, as also are 25 miles of Bayou Nezpique, its tributary, and Mud Lake, all in Louisiana, which has a score of navigable waterways. The lower reaches of the Bayou Queuc de Tortue, also a tributary of the Mermenteau, is being improved for a distance of 14 miles above its mouth. The lower section of the Bayou Plaquemine Brule, another tributary of the Mermenteau, is being improved for a distance of 19 miles so as to have a channel six feet deep and 60 feet wide. Calcasieu River widens out and forms a lake of the same name 25 miles north of the Gulf of Mexico. The lake is 18 miles long and shallow. The river, including the lake, is provided with a channel for 72 miles, which is the head of boat navigation of not less than six feet in depth. This improvement is carried through Lake Charles and West Lake, where

there are several wharves and boathouses. The mouth of the bayou is also protected by two converging jetties one and one-half miles long projecting out into the Gulf and there is a channel between them 200 feet wide and 12 feet deep up to the entrance into the river. The channel from that point to a point above Calcasieu Lake is 80 feet wide and eight feet deep. The tonnage over that waterway in 1917 was 763,619 tons.

*Texas.*—The Galveston, Tex., district includes 25 rivers and harbors. The entrance to Galveston Harbor is protected by two rubble-stone jetties extending from Galveston Island, which is 28 miles long, and Bolivar Peninsula out into the Gulf. The former is six and three-fourths miles and the latter is four and three-fourths miles long, their outer ends being 1,000 feet apart. The channel is 30 feet deep and 800 feet wide. Galveston channel is 30 feet deep and 1,200 feet wide from the outer end more than four miles westward to 51st street in Galveston, which is to be extended, but at the reduced width of 1,000 feet to 57th street. The seawall five miles long protecting the entrance to the harbor is to be extended. The terminal facilities include a wharf system adequate to accommodate 63 or more ocean vessels, several miles of piers, grain elevators, transfer carriers and warehouses. The tonnage of the port of Galveston in 1917 was 2,965,937 tons and the number of vessels entering and departing from the port during the year was 1,539. A channel 200 feet wide and 30 feet deep and four miles long connects Galveston Harbor with Port Bolivar at the end of the Bolivar Peninsula, where there is a turning basin 1,000 feet square. The port is equipped with slips, piers, wharves and warehouses. Its tonnage in 1917 was 109,227 tons. The Houston Ship Canal, 25 feet deep and 150 feet wide on the bottom, extends from Galveston Harbor across Galveston Bay, with a bottom width, up the Jacinto River and Buffalo Bayou to a turning basin 600 feet in diameter at Long Beach and thence by a channel eight feet deep and 40 feet wide through Buffalo Bayou to Houston, Tex. The entire length of the improved waterway is 50 miles. It is protected through upper Galveston Bay by a dike nearly five miles long. There are docks, warehouses, terminals, railway tracks and other terminal facilities at Houston and a regular line of steamships between Houston and New York City. The tonnage of Houston in 1917 was 1,161,424 tons. Some other bayous and streams entering Galveston Bay have been improved for short distances under various river and harbor acts of Congress, authorizing the improvement of West Galveston Bay channel, Double Bayou and the mouths of adjacent streams. In 1851-53 the West Galveston Bay and Brazos River Canal was constructed paralleling the coast but from one to four miles therefrom. It was 10 miles long and had a depth of six feet and a width of 100 feet. It was purchased by the United States government in 1892 at a cost of \$30,000. A new waterway with a channel five feet deep and 40 feet wide on the bottom is being constructed from West Galveston Bay, through Oyster Bay and along the route of the Galveston and Brazos River Canal to Brazos River. Chocolate and

Bastrop bayous and Oyster Creek are commercially tributary to that waterway. A channel between Brazos River and Galveston Bay, a distance of 32 miles, is 100 feet deep and 40 feet wide on the bottom at the mouth of Brazos River and at Matagorda Bay. That forms a part of the 202 miles of waterway extending from Galveston to Corpus Christi. The Guadalupe River is 100 feet deep and 40 feet wide bottom for 52 miles to Victoria from San Antonio Bay, which is 16 miles across, also dredged to similar dimensions to the mouth of the inland waterway.

The channel from Pass Cavallo to Lavaca, Tex., a distance of eight miles, is 100 feet deep and 40 feet wide. The channel from Pass Cavallo, the mouth of Matagorda Bay, to Aransas Pass, Tex., through Espiritu Santo, San Antonio Bay and Aransas bays and is 63 miles long also to have a depth of five feet and a width of 40 feet. It is equipped with wharves at Aransas Bay and at some other places. Aransas Pass it follows Turtle Cove and through Corpus Christi Bay. That section of the inland waterway is 21½ miles long. The port of Galveston Harbor is at the mouth of Brazos River and is protected by parallel north and south jetties a mile more or less in length, being improved for six and one-half miles to Velasco, the channel being 18 feet deep and 150 feet wide. There are some wharves open to the public and regular sailings of vessels therefrom to New York. The tonnage of the port in 1917 was 334,693 tons.

The Brazos River is 950 miles long and navigable to Bolivar Landing. It had a depth of four to 20 feet above that point. At Washington, 25½ miles from its mouth that section is to be cleared. There is no traffic on that river. It has been proposed to improve its channel to a depth of four feet far as Waco by the construction of lock dams and by dredging the open channel 100 miles. Aransas is to be protected by two stone jetties, the north two and three-fourths miles and the south one and three-fourths miles and by a dike on Saint Joseph Island, 1½ miles three-fourths miles long, connecting with the north jetty.

The channel up to the town of Port Arthur is 100 feet wide and 17 feet deep, but toward the Gulf it is 400 feet wide and 20 feet deep and still farther out it is 1,200 feet wide and 25 feet deep out between the jetties, the dredged channel is to be 600 feet wide. Harbor Island Basin will be thus extended. Other channels have been dredged at Harbor Island Basin.

The Dallas district includes 11 river and harbors. Port Arthur Canal, seven miles extends from Sabine Pass to Port Arthur, Tex., docks near Taylors Bayou. Sabine Pass Canal, 10 miles in length with a width varying from 100 to 5,000 feet, connects Sabine Lake with the Gulf of Mexico. Its entrance is protected by extending out four miles, between which is a channel 26 feet deep and 200 feet wide. The channel through Port Arthur Canal is 26 feet deep and 150 feet wide to Fort Belknap, where there are two turning basins ;

deep, one 600 feet by 1,700 feet and the other 420 feet by 1,800 feet. At Sabine are wharves and other facilities. In 1917 the tonnage on the Port Arthur Canal was 6,984,286 tons.

That canal cost \$1,029,982 and was transferred to the United States government without charge. The Sabine River, 550 miles long and 700 feet wide, enters Sabine Lake through three passes. Neches River, 300 miles long and 650 feet wide, flows into the same lake. A new waterway starting from Port Arthur Canal has a channel 25 feet deep and 90 feet wide through the land and 115 feet wide in the open lake and 150 feet wide in the open rivers and extends through the Sabine-Neches Canal and Neches River to Orange on the Sabine River and from the mouth of Neches River to Beaumont on that river, terminating in a turning basin 500 feet by 1,500 feet on each stream. There are some terminal facilities at Beaumont in touch with ocean-going vessels. The tonnage over the Sabine-Neches Canal in 1917 was 1,437,489 tons and on the Sabine River 215,605 tons and on the Neches River was 1,066,310 tons. Trinity River, Texas, 760 miles long and discharging into Galveston Bay, is being improved by the construction of dams and locks and by dredging. Thirty-seven locks and dams were recommended by the Engineers of the United States Army. Those locks have chambers 140 feet long, 50 feet wide and a navigable depth of six feet over the mitre sills. In 1917 only nine locks were completed and navigation was practicable as far as Liberty, 41½ miles above the mouth of Trinity River. To completely canalize the river to Dallas Tex., 512 miles above its mouth and 370 feet above the tide water, is the present project partially completed. The city of Dallas is bearing part of the expense.

*Other Gulf-State Waterways Development.*—Red River is 1,275 miles long and from its mouth in Louisiana to Fulton, Ark., the distance is 482 miles. It is under improvement. From Fulton to Shreveport, La., there is a minimum depth of five feet and from Shreveport to its mouth there is a minimum depth of seven feet from December to June when the water is high and the river within its improved sections may be navigated, but not at other times. At high stages of water light draft vessels have and may still ascend as far as Denison, 763 miles above its mouth and 11 miles below the outlet of the Washita. At Denison there is in some months a depth of five feet in the channel. Lanesport, 75 miles above Fulton, formerly was at the head of navigation, though boats occasionally ascended to the mouth of the Kiamichi, 158 miles above Fulton, Ark. Some clearings of the channel and dredging has been done in the lower 51 miles of the Sulphur River, and during high water in the Red River there is a back-water flow into Sulphur River for 50 miles which render the lower reaches of the latter navigable for light draft steamboats for a distance of 17 miles for rather irregular and short periods of time. The channel of the lower part of Cypress Bayou for 66 miles is being dredged and straightened from Red River at Shreveport, La., to Jefferson, Tex. A dam has been constructed without a lock at the foot of Caddo Lake, which is 17 miles across. That dam creates a pool extending 43 miles to Jefferson City,

Tex., which insures a navigable waterway four feet deep.

The Vicksburg, Miss., district comprises 16 rivers and harbors, some of which have already been described. The Ouachita River, Arkansas, is being improved by the construction of eight locks and dams and by clearing the channel so as to afford a navigable depth of six and one-half feet of water from the mouth of Black River, Louisiana, to a point 10 miles above Camden, Ark., a distance of 360 miles. The lock chambers are 55 feet wide and 268 feet long and have lifts of five and one-half to 14¾ feet. In 1917 the tonnage over that waterway was 178,136 tons. The Tensas, which has its source in Lake Providence and is 235 miles long, joins the Ouachita and Little rivers to form the Black River, Louisiana. The Tensas receives, as a tributary, Bayou Mason, which is 270 miles long. The channels of both of those streams are being cleared and improved to make the Tensas navigable from Westwood Place, 81 miles above its mouth, and Bayou Macon from Floyd, 112 miles above its mouth, so as to afford a navigable depth of six feet from January until June. At high stages those channels are 150 feet wide and eight feet deep. The traffic on the two streams in 1917 was 8,344 tons on the sections improved. Boeuf River, Bayou Bartholomew, Saline River, Bayous D'Arbonne and Coney are navigable for light draft vessels in their lower reaches during the months of high water. The Yazoo River, a tributary of the Mississippi, has a channel four feet deep and 500 feet wide its entire length of 178 miles. Loaded boats thereon draw four feet of water. The tonnage of that river in 1917 was 102,418 tons. The lower 115 miles of the Tallahatchie and the lower 40 miles of the Coldwater rivers have been made navigable for vessels of three feet draft. Big Sunflower River, a tributary of the Yazoo River, is 216 miles long and is to have a navigable depth of four and one-half feet and a navigable width of 100 feet for 171 miles above its mouth. In 1917 its tonnage was 61,017 tons. Several other smaller streams in that district have been improved.

The mouth of the Yazoo River is opened up through Lake Centennial to the Mississippi for a distance of nine and three-tenths miles with a bottom width of 98½ feet and a depth of six and one-half feet. The canal is navigable all the year. In 1917 its traffic was 61,657 tons.

The lock and dam in the Big Sunflower River at Little Callao Landing, Miss., create a pool of varying depth of one to 22 feet for 61.8 miles up stream and render the river navigable to Pentecost, Miss., 124½ miles above its mouth. The Little Rock, Ark., district comprises five rivers and the locks and dams on the upper White River. The Arkansas River, 1,460 miles long, a tributary of the Mississippi, is to be improved from its mouth to Neosho (Grand) River, 461 miles. The Grand is navigable to Fort Gibson two miles from its mouth. Under ordinary conditions from February to July the Arkansas has a navigable depth of four feet from its mouth to Little Rock, 174 miles, and some years it has a navigable depth of three feet as far as Fort Smith, 369 miles above the mouth. In 1917 steamboats ascended the river to Littles, 202 miles above its mouth, and gasolene boats ascended to Dardanelle, 261

miles above its mouth. Steamboats with barges of three to four feet draft operated as far as Little Rock for four and one-half months in 1917. The tonnage on that river in 1917 was 38,659 tons. The White River, 690 miles long, a tributary of the Mississippi, is being improved from its mouth to Batesville, a distance of 301 miles, by the construction of works, dredging, etc. A lock and dam has been constructed one mile below Batesville, a second lock and dam seven and eight-tenths miles above Batesville and a third lock and dam nine and seven-tenths miles above Batesville, thereby affording all-year slack-water navigation for vessels of three feet draft from the first dam to Guion, a distance of 33 miles farther up stream. The locks are 147 feet long, 35 feet wide, and have six feet of water over the mitre sills. At low water in 1917, its controlling channel depth was three and one-half feet from its mouth to Grand Glaize, a distance of 241 miles, and three feet from Grand Glaize to Jacksonport, a distance of 123 miles, and 14 to 16 inches from the latter port to Batesville. Forsyth, Mo., 505 miles above the mouth of the White River, was at the head of steamboat navigation. For seven and one-half months in 1917 a channel depth of six feet obtained from the mouth to Devall Bluff, a distance of 124 miles. In 1917 the tonnage on the White River was 205,198 tons and that through the three locks was 16,014 tons.

The Arkansas and White rivers enter the Mississippi River through a common inlet. The Black River in Kansas and Missouri is 300 miles long and flows into the White River at Jacksonport. It is being dredged and being made navigable from its mouth to Poplar Bluff, Mo., a distance of 239 miles, by boats of 18 inches draft and by boats of two and one-half feet to the mouth of Current River, a distance of 116 miles. In 1917 boats of three and one-half to five feet draft operated below Current River and boats of two feet draft above Current River two months. The Black River tonnage in 1917 was 154,281 tons. The Current River is 200 miles long and is being cleared of snags from its mouth to Van Buren, Mo., a distance of 94 miles, so that flatboats may ascend that far and have ascended 33 miles farther up the river to Jack's Fork. In high water steamboats ascend from the Black River as far as Pitman's Landing, 41 miles above the mouth of Current River. In 1917 the controlling channel depths were to Duff's Ferry, 32 miles above the mouth, three and one-half feet; to Doniphan, 53 miles up stream, 14 inches, and to Van Buren, from 10 to 12 inches. The tonnage in 1917 was 16,762 tons.

Some work has been done toward clearing the lower reaches of the Saint Francis River, 460 miles long, the L'Anguille River and the Blackfish Bayou to render the same navigable for boats of four-foot draft at medium and high stages of water from January until August, but the controlling depths in L'Anguille River and in Blackfish Bayou are due to the backwater stages of the Mississippi River. In 1917 a steamboat of three-foot draft operated as a weekly packet in the Helena- (on the Mississippi) Marianna- (on the Saint Francis) Blackfish commerce. The Saint Francis River to Marked Tree, the Blackfish Bayou to Fifteen Mile Bayou and the L'Anguille to Marianna are

navigable by boats of four-foot draft or high water. The aggregate tonnage on these three streams in 1917 was 344,278 tons.

**The Mississippi System.**—The Mississippi River has a total length of 2,471 miles. Its channel has a depth of 35 feet from the Gulf of Mexico to New Orleans about 104 miles. Passes to New Orleans about 104 miles above the Gulf of Mexico and a depth of 30 feet from point 227 miles above the Head of Pass. It has a width of 250 feet. From 833 miles to the mouth of the Ohio channel has a depth of nine feet and a width of 250 feet and thence to Saint Louis, a distance of 188 miles, its channel has a minimum depth of eight feet and a width of 250 feet thence to the mouth of the Missouri, a distance of 17 miles, its channel has a depth of 17 feet at low water and a width of 250 feet. From the mouth of the Missouri River to Twin City Lock and Dam, it is 664 miles. From Washington Avenue Bridge at Minneapolis to the head of navigation, it is 669 miles. From 1,955 miles from the mouth of the Mississippi to the head of navigation, the channel is to have a depth of six feet and a width of 300 to 1,400 feet, to be obtained by means of contracting works consisting of main and spur dams for narrowing the channel of the river. In 1918 the depth of the channel at Rock Island Rapids at the lowest stage was only four feet. From Cape Girardeau to Rock Island, Ill., a distance of 452 miles, the Mississippi for most of the way is private levees as it is for 1,503 miles below Cape Girardeau. The channel has been improved in various places below Cairo. At Keokuk, 496 miles below the head of navigation, there are 496 miles above the outlet of the Missouri a power dam of 41 feet crest with a width of 110 feet long, 110 feet wide with six feet of water over mitre sills. There is also a dry dock 380 feet long, 140 feet wide with entrance 110 feet wide. During the 252 days of navigation in 1917, steamboats to the number of 2,000 and launches to the number of 2,000 through that lock. That replaces the Moines Rapids Canal.

The Moline Lock and Dam at the Rock Island Rapids, 366 miles below the head of navigation, has a length of 350 feet, a crest 80 feet and a depth of six feet of water over mitre sills. One hundred and fifty-foot boats, 74 barges and 270 launches passed it during the 265 days of navigation. That lock overcomes the swiftest passage through the Rock Island Rapids. Le Claire Canal proposed 360 miles below the head of the Mississippi of the same dimensions as those of the Moline Canal.

Provision has been made for the construction of a power dam with a lock 350 feet wide and having a lift at low water of 10 feet between Minneapolis and Saint Paul. This will make it possible for vessels to transport grain from the elevators and flour mills at Minneapolis to the Gulf of Mexico by ocean carriers without transshipment. The depth of water over the mitre sills will be seven to 10½ feet. The upper Mississippi from Saint Paul to Brainard, a distance of 100 miles, is navigable for light draft vessels. From Brainard to Grand Rapids, a distance

miles, it is to have a channel 60 feet wide and three and one-half feet deep at mean low water. A similar improvement has been made in the river between Aitkin and Grand Rapids, a distance of 125 miles and three and one-half feet depth has been secured. The large natural reservoirs at the head-waters of the Mississippi River, in addition to Itasca Lake, its source, and Cass Lake, 283 miles above Brainard, the head of navigation, include Winnibigoshish Lake, Leech Lake, Pokegama Lake, Sandy Lake, Pine River and Gull Lake, having an aggregate capacity of  $97\frac{3}{4}$  billions cubic feet. Their discharge is regulated by dams and controlling works at their several outlets and their waters keep up a uniform flow in the Mississippi as far down as Lake Pepin, 52 miles below Saint Paul. The waters of Winnibigoshish and Leech Lakes reservoirs flow into Pokegama reservoir and thence into the Mississippi. The Leech River has been dredged and improved for 27 miles and has a channel 100 feet wide and eight feet deep and the channel of the Mississippi was made eight feet deep and 100 feet wide above the Leech River and 125 feet wide below that river, that entire section of the Mississippi improved being 65 miles in length. New Orleans has five miles of wharves, of which three and one-half miles are covered with steel sheds. Natchez has some wharves and old landings. The harbor at Memphis is subject to thick deposits and requires much dredging as do many other harbors along the Mississippi.

The Saint Croix River flowing through Lake Saint Croix, which is  $25\frac{1}{2}$  miles long, and into the Mississippi, 26.9 miles below Saint Paul, is being improved to obtain a channel three feet in depth from its mouth to Taylor's Falls, a distance of 52.3 miles.

The Minnesota River, 450 miles long, is to have an open channel to accommodate vessels of four-foot draft from its mouth at Saint Paul to Shakopee, a distance of 25.6 miles.

Lake Traverse, one of the sources of the Red River of the North, is 25 miles long and through its narrows is to have a channel 50 feet wide and four feet deep.

The Red River of the North flows northerly between Minnesota and North Dakota about 350 miles and thence along the International boundary and thence into Lake Winnipeg. From Breckenridge to Moorhead, a distance of 97 miles, it is to have a navigable channel during high and medium stages of water; from Moorhead to Grand Forks, a distance of 155 miles, it is to have a channel 50 feet wide and three feet deep, and from Grand Forks to the International Boundary, a distance of  $143\frac{1}{2}$  miles, it is to have a channel 60 feet wide and four feet deep at low water. Red Lake River between Thief River Falls and Red Lake, a distance of 71 miles, is to have a channel of three feet depth. Regulating works are being constructed at the outlet of that lake to control its discharge and the flow of the river in the interest of navigation. Warroad Harbor and Warroad River are southwest of the Lake of the Woods. The harbor has a wharf open to the public and the river, 26 miles long, connecting the harbor with the lake, has a depth of eight feet. In 1917 the tonnage of the harbor was 8,500 tons. A harbor of refuge has been constructed in Zippel Bay on the south shore of the Lake of the Woods.

The Missouri River from its mouth to Kansas City, a distance of 398 miles, is to have a permanent channel six feet deep and 1,200 feet wide, though in 1917 the draft of steamers was three and one-half feet and that of barges from four to four and one-half feet, but in low water it was from three to three and one-half feet. From Kansas City to Sioux City, Iowa, a distance of 409 miles, in 1917, it had a channel four feet deep, though the loaded draft of boats did not exceed two and one-half feet. From Sioux City to Fort Benton, Mont., the head of navigation, a distance of 671 miles, loaded vessels had an average draft of two feet in the upper reaches of that section of the river. The lower reaches of the Osage River from its outlet into the Missouri up to Linn Creek, a distance of 109 miles, are to have an open channel 80 feet wide and three feet deep. A lock 220 feet long and 42 feet wide with an available depth of nine feet of water over the mitre sills and with a lift of 16 feet has been constructed seven miles above its mouth. That has made the lower 109-mile section navigable for light draft vessels. In 1917 its commerce was 28,171 tons. The Gasconade River is being cleared of obstructions from its mouth to Gascondy, a distance of 61.4 miles. It had in 1917 a channel of only nine inches navigable depth in some sections and two feet in others. It had a score of small warehouses in the lower  $39\frac{1}{2}$  miles of its course and a tonnage in 1917 of 24,523 tons.

The Cumberland River in Tennessee and Kentucky has been improved from Burnside, the head of navigation, to its mouth, a distance of 418.7 miles. That has been done by dredging and by the construction of locks and dams in its several sections. The average width between Burnside and Nashville, 326.1 miles below, is 300 feet and from Nashville to its outlet into the Ohio River, a distance of 192.6 miles, it has a width of 400 to 500 feet. The channel between Burnside and Nashville is 150 feet wide and six feet deep at low water. There are six locks and dams in that section of the river below Nashville. Locks A, B and C are 280 feet long by 52 feet wide, with six feet of water over the mitre sills, and have lifts of 12 feet. Locks D, E and F are 310 feet long and 52 feet wide with six and one-half feet of water over the mitre sills and have lifts of 10 to 13.3 feet. These have made the lower Cumberland navigable to Nashville and its tonnage in 1917 was 131,325 tons. In the section above Nashville, the river is navigable for light draft vessels for four or five months in the year during high water. Above Nashville are locks 1, 2, 3, 4, 5, 6, 7 and 21 (locks 8 to 20 and 22 proposed in the original plans having been eliminated), each 280 feet long and 52 feet wide with six and one-half feet of water over the mitre sills and with lifts of six to 14 feet. These structures set the water back so that a navigable depth of six feet will be provided within four miles of Burnside and over that distance a navigable channel of four feet depth will be obtained. The total water-borne commerce at Nashville in 1917 was 267,091 tons. That will undoubtedly materially increase after the improvement has been completed and boat lines are established. The Board of Engineers of the United States army have recommended the construction of 10 additional locks, namely eight to 17 as originally planned, provided that the

States, counties and local agencies will save the United States harmless from claims for damages due to overflowing lands along that section of the river. The total commerce passing through all the locks in 1917 was 683,529 tons.

*Tennessee.*—The Tennessee, 652 miles long and formed by the junction of the French Broad and Holston rivers, four and one-half miles above Knoxville, Tenn., flows southwesterly into Alabama and westerly across the northern part of that State and thence northerly into and across Tennessee and northwesterly into and across Kentucky into the Ohio River about 36 miles above the outlet of the latter into the Mississippi. Above Chattanooga it is 700 feet wide, but below it is 1,000 feet wide and at Muscle and Colbert Shoals it is more than 1,000 feet wide. From its head to Chattanooga, a distance of 188 miles, it is to have a channel 150 feet wide and three feet deep. A concrete dam and lock 265 feet long and 60 feet wide with six and one-half feet of water over mitre sills and with a lift of 25.7 feet is at the foot of Caney Creek Shoals, which sets the water back for 24.6 miles, making a navigable depth of six feet. That 188-mile section is navigable for boats of three-foot draft, however, only when the water is at high stages from January to June. For short periods boats of four-foot draft may navigate parts of that section, but boats of only one foot draft can navigate that section all the year. Both Knoxville and Chattanooga have a wharf with a warehouse equipment with conveyors. The shoals in the upper reaches of the Tennessee are being dredged. The total river tonnage above Chattanooga for the year 1917 was 613,243 tons. Chattanooga is 464 miles above the mouth of the Tennessee. At Hale's Bar, 33 miles below Chattanooga and 431 miles above the mouth of the Tennessee, is another concrete dam and lock, 267 feet long and 60 feet wide, with six and one-half feet of water over the mitre sills and with a lift of 37½ feet. That sets the water in the river back and affords a navigable depth of six feet as far as Chattanooga. The tonnage through that lock in 1917 was 15,681 tons. Concrete dams and locks are to be constructed at Widow's Bar, 56.1 miles below Chattanooga and Bellefonte Island, 72.1 miles below Chattanooga, or one concrete dam 17.9 feet high and a lock at the latter place to provide a navigable channel of six feet depth. The locks are to be 265 feet long and 60 feet wide with six feet of water over the mitre sills. The project announced by the War Department in 1917 provides for an open channel, 150 feet wide and five feet deep at extreme low water between Hale's Bar and Brown's Island, that section being 138 miles long, except in those parts of that section that may be canalized. The Muscle Shoals Canal opened in 1890 and comprises two sections, aggregating about 18 miles in length. It had 11 locks from 275 to 283 feet in length and all 57 feet in width with different lifts, ranging from three and nine-tenths to 13.1 feet and having from two and two-tenths to seven and five-tenths feet of water over the mitre sills. The locks in the 36.6 miles of rapids above Florence overcome 134 feet of fall in the river. The existing project provides for the construction by the United States government of new locks, dams and a power-house, securing nine and one-half feet of water for 14.7 miles and a

depth of five feet of water in the canals at extreme low water. The construction of dam No. 2 was approved in 1918. It is two and seven-tenths miles above Florence with locks 300 feet long, 60 feet wide and total lift of 90 feet. When the new project is completed, old locks Nos. 3 to 9, inclusive, will be submerged, but old locks Nos. 1 and 2 and locks A and B on the Elk River Shoals section will remain in service. This improvement not only provided for the navigation of the Muscle Shoals section of the Tennessee, but also for the generation of electric power for the production of some of the nitrates used during the World War. A bill is now pending in Congress for the nationalization of that nitrate plant.

From Florence, 208 miles below Chattanooga and 256.5 above the mouth of the river to Colbert Shoals, the available depth of channel at extreme low water is five feet throughout the year. In that section is the Colbert Shoals Canal on the left bank of the river and nearly eight miles long with a depth of six feet over mitre sills. Its width is 140 feet. Its single lock is 350 feet long and 80 feet wide with a lift of 26 feet. The river tonnage between Chattanooga and Florence in 1917 was 170,968 tons and through that canal was 38,286 tons.

The Tennessee from Riverton to its mouth, a distance of 226.5 miles, is to have a channel 150 feet wide and six feet deep at ordinary stages of water and at five feet deep at extreme low stages. The draft of boats in that section of the river varies from two to six feet. The tonnage below Florence in 1917 was 416,304 tons. The French Broad River has been made navigable for steamboats of two-foot draft up to Dandridge, 46½ miles above its mouth, and at stages of high water as far as Leadvale, 69½ miles above its mouth. The tonnage thereon in 1917 was 129,201 tons.

Clinch River, a tributary of the Tennessee 103½ miles above Chattanooga, is being provided with a navigable channel two feet deep from its mouth to Clinton, Tenn., a distance of 60 miles, and a channel one and one-half feet deep from Clinton to Walker's Ferry, a distance of 66 miles. The usual draft of boats varies from 15 inches to three feet, but during periods of low water there is little or no navigation of parts of the river. Its tonnage in 1917 was 8,983 tons. The United States Engineers have recommended that no further moneys be expended in its improvement. The Hiwassee River rises in northern Georgia and empties into the Tennessee, 36½ miles above Chattanooga. Its channel is being improved for 35 miles above its mouth and is to have a width of 154 feet and a depth of three feet in the centre and two and one-half feet the entire width of the channel. It has been navigated as far as Savannah Ford, though its present steamboat traffic does not extend above Charleston, Tenn., 19 miles above its mouth. Its tonnage in 1917 was 2,152 tons.

*North Middle States.*—The next great waterway of the United States is the Ohio River, which is formed by the junction of the Allegheny and Monongahela rivers at Pittsburgh, Pa. Thence it flows southwesterly 968½ miles into the Mississippi River at Cairo. The section between Pittsburgh and Steubenville, Ohio, a distance of 65.7 miles, has dams Nos. 1 to 10, the section from Steubenville to a point two

miles below Huntington, W. Va., a distance of 245.2 miles, has dams Nos. 11 to 28 and the section from the last-named place to a point two miles above Madison, Ind., a distance of 242.7 miles, has dams Nos. 29 to 40 and the section extends from the last-named place to Mound City, Ill., a distance of 408 miles, and has dams Nos. 41 to 54, inclusive. The Louisville and Portland Canal was completed in 1830 by a Kentucky corporation to overcome the falls in that part of the river. It had three combined lift locks, each of eight and two-thirds feet lift, a width of 50 feet and a length of 200 feet. That has been enlarged and under the existing project it is to be again enlarged. The improvement of the Ohio involves the construction of locks and movable dams so as to provide a minimum channel of nine feet of water in the pools formed thereby and the widening of the Louisville-Portland Canal from 90 to 200 feet. Shoals form in the river and annual dredging is necessary to keep the channel cleared of obstruction and deposits. There are to be 53 locks which are to have usable dimensions of 600 feet in length and 110 feet in width, and having varying lifts from three and one-tenth to 29 feet, most of them having seven and three-tenths to nine feet lifts. Down to 30 June 1918 the total expenditures under the existing adopted project aggregated \$28,578,032.38 on new work and the amount expended on all projects in the improvement of the Ohio for new work aggregated \$46,235,306.16. The tonnage on the Ohio River including that over ferries for 1916 was 7,917,112.61 short tons, and for 1917 was 6,149,213.32 short tons.

*Pennsylvania.*—The Monongahela River is to be made navigable for 130 miles above its mouth by the construction of 15 locks and dams to afford slack-water navigation from Pittsburgh, Pa., to a point four miles above Fairmont, W. Va. The locks have a width of 50 to 56 feet and lengths of 159 to 360 feet, and lifts of four and four-tenths to 12.8 feet and with five to nine and four-tenths feet of water over the mitre sills. The tonnage on the Monongahela in 1917 was 16,000,153 tons.

The Allegheny River is 325 miles long and joins the Monongahela to form the Ohio at Pittsburgh, Pa. It is designed that it have an open channel from its mouth to the New York State line, a distance of 214 miles. Formerly it was the route for the pioneer and traders passing between New York and southern Ohio. Locks 286 to 360 feet long and 55 to 56 feet wide with seven to 11 feet of water over their mitre sills and having lifts of seven to 12 feet are being constructed above Pittsburgh and three have been completed affording slack-water navigation up to Natrona, Pa., a distance of 24 miles with a controlling depth of six and one-half feet. Slack-water navigation is to be extended to Riverton, Pa., a distance of 37 miles. Its tonnage in 1917 was 2,300,143 tons. The harbor at Pittsburgh comprises sections of the Ohio, Monongahela and Allegheny rivers and these are 27.2 miles in length. The channels are from 300 to 800 feet wide and seven to 10 feet deep. Terminal facilities include wharves, docks, hoists of various types and other equipment. The commerce of Pittsburgh for the year 1917 was 14,639,496 tons.

The Youghiogheny River, Pennsylvania, a tributary of the Monongahela, is being improved

by dredging and the construction of three locks, 360 feet long and 56 feet wide, with eight feet of water over the mitre sills and dams between its mouth and West Newton, 19½ miles up-stream, which will afford slack-water navigation to West Newton. The tonnage on that river in 1917 was 85,585 tons.

*Virginia, West Virginia, Ohio and Indiana.*—The Little Kanawha, a tributary of the Ohio, has been improved for a distance of 48 miles from its mouth to Creston by the construction of locks and dams, thereby affording a navigable depth of four feet to Creston. The locks are 125 feet long, 23 feet wide and have a depth of four to 10.2 feet over the mitre sills and lifts of six and four-tenths to 12.4 feet. The tonnage over that river in 1917 was 40,849 tons. The States of Virginia and West Virginia, improved sections of the Kanawha River, also a tributary of the Ohio, and packets and barges ascended the river for a distance of 90 miles at high-water stages. It is 97 miles long. Ten locks, 271 to 313 feet long, 50 to 55 feet wide, with six and five-tenths to 11.35 feet of water over the mitre sills and having five and sixty-five hundredths to 13.67 feet lifts, are being constructed at various sections of the river. All the dams are of the movable type except two. That will afford a navigable channel of six feet depth for 90 miles above its mouth. The tonnage on that river in 1917 was 1,605,495 tons. Sixteen steamboats and 265 other craft navigated the river in 1917. The Wabash River, 517 miles long, flows northwesterly from Ohio across Indiana and southerly between that State and Illinois into the Ohio, 121 miles above the mouth of the latter river. The Wabash in its original condition was 450 to 1,300 feet wide and was navigable at periods of high water, when boats ascended as far as Peru, Ind., 366 miles above its mouth. It has been made navigable in separate sections and at different periods. A lock, 214 feet long and 52 feet wide, and dam at Grand Rapids, 97.1 miles above the mouth, provide slack-water navigation for 12 miles. Through navigation is impracticable on account of the rapids and shallows in some parts of the river. The New Harmony Cutoff, 41½ miles above the mouth, where there is a fall of six and one-half feet, is to be closed and the river dredged to afford a navigable channel of three and one-half feet at low water from the mouth of the river to Terre Haute, 214 miles from the mouth, but boats drawing three feet can make that distance for less than four months of the year. Boats of 20-inches draft can pass from Mount Carmel, 96 miles above the mouth, to Vincennes, 32 miles farther up-stream, at all stages of water, but cannot pass down-stream to the mouth of the river only at very high water. In 1917 about 800 boats passed through the locks at Grand Rapids. One of the principal tributaries of the Wabash River is the White River, formed by the confluence of the East and West Forks about 50 miles above its entrance into the Wabash. It is navigable in its lower reaches for light-draft boats. The Scioto, Maumee and Miami rivers formerly were navigable and the latter two are in the route of the projected Miami and Erie Canal across Ohio.

*Kentucky and Ohio.*—The Green and Barren rivers in Kentucky are being improved by

the construction of six locks and fixed dams in the former, a tributary of the Ohio, and one lock and dam in the latter, a tributary of the Green River. The locks are 138 to 142 feet long and 35 to 35.6 feet wide, with six to eight feet of water over the mitre sills and having lifts of 11 to 20 feet. That improvement renders the Green River navigable for boats of five-foot draft all the year from lock No. 1 at Spotts-ville to Mammoth Cave, Kentucky, a distance of 187½ miles, or to Bowling Green, Ky., on Barren River, a distance of 171 miles from lock No. 1 on the Green River. The tonnage in 1917 was 252,841 tons. Rough River, Kentucky, 125 miles long, another tributary of the Green River at Livermore, has been cleared of obstructions and a lock and dam have been built near Livermore, Ky. The lock is 125 feet long and 27 feet wide, with four and nine-tenths feet of water over the lower mitre sills, and having a lift of nine and four-tenths feet. That structure sets the water back and affords slack-water navigation to Hartford, Ky., 29½ miles from the mouth for boats of four-foot draft. Its tonnage in 1917 was 12,701 tons.

The Muskingum River is being improved from its outlet into the Ohio River at Marietta up to Dresden, a distance of 91 miles, by the construction of 11 locks and dams and four short lateral canals, affording a minimum depth of five and one-half feet. All the locks are 35½ feet wide and 160 feet in length with the exception of lock No. 10 which is 159 feet long, and lock No. 1 which is 55½ feet wide and 360 feet long. The depth of water over the mitre sills is six feet or more and the lifts vary from four and eight-tenths feet to 15.1 feet. There are several warehouses along the river and its tonnage in 1917 was 92,426 tons. The improvement may be extended through the valley of the Cuyahoga to form the Ohio and Erie Canal. The Big Sandy River, on the boundary between Kentucky and West Virginia, formed by the junction of the Levisa and Tug Forks, flows north 27 miles and empties into the Ohio 10 miles below Huntington. Its improvement involves the construction of three locks and dams. Two locks and dams are being constructed on each of the Levisa and Tug forks. The locks are about 158 feet long and 54½ feet wide. The improvement has rendered the Big Sandy River navigable by vessels of six-foot draft 27 miles to Levisa and the Levisa Fork navigable for 18 miles, and the Tug Fork navigable for 12 miles by vessels of six-foot draft. The tonnage on those rivers in 1917 was 88,344 tons.

**Kentucky.**—The Kentucky River, formed by the North, Middle and South forks, is 255 miles long and empties into the Ohio at Carrollton, Ky. It is being improved by the construction of 14 locks and fixed dams.

That affords slack-water navigation for vessels of six-foot draft to points on the three forks above Beattyville, Ky., a distance of 280 miles. The lower five locks are 145 feet long and 37 to 38 feet wide, with six and one-tenth to six and eight-tenths feet of water over the mitre sills and having lifts of 12½ to 17 feet; these afford slack-water navigation for 88 miles. The remaining nine locks are 146 feet long and 52 feet wide, with six to seven feet of water over the mitre sills, and lifts from 14.4 to 18 feet.

Slack-water depth of five feet has been for 260 miles up from the mouth of and the additional foot will be obtained as the dredging is completed. In 1917 tonnage was 148,981 tons. Some years ago the Licking River was improved from its mouth into the Ohio 125 miles up to West Liberty.

**Great Lakes System.**—The Fox River, 125 miles long, in Wisconsin, is divided into upper and lower Fox by Winnebago Lake, which has a depth of six feet from Deperetello, a distance of 125 miles, and a four feet from Montello to Portage, of 31 miles, and a width from Lake Winnebago to Montello of 100 feet. The lower Fox is 300 to 3,000 feet wide and 39 miles long; in course it has 27 locks and 16 dams. The upper Fox is 136.4 to 148.6 feet long and 20 to 40 feet wide, the water over the dam varies from one and two-tenths to 14 feet. Wolf River, which flows into it 10 miles from Oshkosh, is being improved from its mouth to New London, a distance of 47 miles. That affords navigation for vessels of four-foot draft.

The head of navigation on the Fox is at Portage, except that during high water the Fox River, boats can proceed from Portage into Wisconsin River and thence into the Mississippi. The tonnage on the Fox River in 1917 was 161,060 tons. The further improvement of the Wisconsin River has been that of clearing the channel of obstructions. Formerly the Wisconsin River, a tributary of the Mississippi, 600 miles long, and the Fox River, 200 miles long, with a connection formed a continuous waterway from the Mississippi to Lake Michigan. It was declared a public highway. Grand Haven, Michigan, has also been declared a public highway. It has an improved channel, 100 feet wide and six feet deep, from Grand Haven to Grand Rapids, a distance of 38 miles.

A ship canal connects Sturgeon Bay, Wisconsin, to Lake Michigan. It is 7,200 feet long from 160 to 250 feet wide, and the depth being continued into Sturgeon Bay, of four miles, having a width of 200 feet and a depth of 19 feet at low water datum. The tonnage through that canal was 7,000 tons and the harbor afforded shelter for 100 vessels.

The Chicago River, formed by the North and South branches, flows into the Sanitary Canal and is only one mile long. It has a channel 21 feet deep at low water datum in Lake Michigan. The distance of navigation is Belmont avenue, 6¼ miles, and fourteenth miles on the North Branch, Ashland, four and eight-hundredths miles on the South Branch. In the Chicago River there are numerous slips, docks and other facilities. The Calumet River is seven and one-half miles long and empties into Lake Michigan 12½ miles south of Chicago. It is formed by Little Calumet River, 10 miles long, and Grand Calumet River, 18 miles long, and Grand Calumet River, a lagoon 18 miles long. The entrance to the Chicago River is to be 200 feet wide and 21 feet deep and the improvement is to be extended five and forty-seven-hundredths miles to "The Forks," with turning basins at intermediate points.

The river is navigable by vessels of six-foot draft from The Forks to In

2 Great Lakes vessel, partially dismantled, passing through the Barge Canal for ocean use during war emergency

Canal, and by vessels of six-foot draft to Riverdale on the Little Calumet, a distance of 12 miles from the mouth of the river. The entrance to the harbor is protected by parallel breakwaters. The tonnage of the river and harbor in 1917 was 10,269,304 tons. The Illinois River, formed by the junction of the Kankakee and Des Plaines rivers, empties into the Mississippi 36 miles above Saint Louis. It is 273 miles long. Years ago it was navigable by Mississippi boats from its mouth as far as Utica, a distance of 230 miles. It is now being improved to secure a seven-foot depth at low water from La Salle, the head of navigation, to its mouth, a distance of 223 miles, by lock and dam construction and dredging. The locks are 325 feet long and 73 feet wide, with seven and seven-tenths feet of water over the mitre sills and with seven-foot lifts. The State of Illinois is co-operating with the United States government in that improvement. The tonnage over the improved sections of the river in 1917 was 284,970 tons and the number of passengers transported was 32,574. When improved, the Illinois River will form a part of a continuous waterway from the Mississippi to Lake Michigan, the other connecting sections being the Illinois and Michigan Canal, 63 miles long, extending from La Salle to Joliet and the Chicago Sanitary or Drainage Canal extending from Joliet to Lake Michigan. The Illinois and Michigan Canal, when constructed was 96 miles long and extended to the South Branch of the Chicago River at Chicago. It had a bottom width of 40 feet, a surface width of 60 feet and a depth of six feet, and 11 locks, which were 103 feet long and 17 feet wide, and had five to six feet of water over the mitre sills. That canal has been repaired and restored to a navigable condition. Another waterway connecting Lake Michigan and the Mississippi River is the Illinois and the Mississippi Canal, proceeding from the Illinois River at a point one and three-quarters miles above Hennepin, via the Bureau Creek Valley and over the summit to Rock River, and down that river to the Mississippi. It has a surface width of 80 feet, a depth of seven feet and 33 locks 150 feet long and 35 feet wide. The main canal is 75 miles long and has a navigable feeder extending from Rock Falls on Rock River to the summit level. Some improvements have been made in that canal, which were completed in 1918. Its tonnage in 1917 was 15,662 tons and 32,377 passengers were transported. The Keweenaw waterway, partly natural and partly artificial, 25 miles in length, extends across Keweenaw Point in Michigan. It is a navigable channel 20 feet deep with a bottom width of 120 feet, along which there are 32 privately owned docks. It affords access to a harbor of refuge for Lake Superior vessels. The tonnage passing through it in 1917 was 558,456 tons.

Saint Joseph River in Michigan and Indiana was at one time navigable as far as South Bend, a distance of 50 miles. It now has a channel from 30 to 50 feet wide and from two to three feet deep, at low water, from its mouth into Lake Michigan at Saint Joseph up to Berrien, a distance of 22 miles. The harbor at the outlet including the outlet of the Pawpaw River and the Benton Harbor Canal is two and one-tenth miles long, with a channel 18 feet deep and 150 feet wide, two-thirds of a mile

long, a turning basin and a canal 15 feet deep and 100 feet wide to Benton Harbor. The tonnage of that port in 1917 was 115,138 tons. Saginaw River in Michigan has been improved and has a channel, 200 feet wide and 18½ feet deep, from Saginaw Bay to the mouth of the river three and one-quarter miles and thence 16½ feet deep to its source, a distance of 22 miles. There are several thousand feet in length of docks in and between Bay City and Saginaw, which are situated on that waterway. The lower three and one-quarter miles of the channel of Black River in Michigan has been dredged to a depth of 17 feet and the width of 160 decreasing to 75 feet. Boats of small draft ascend the river five miles beyond the improvement. There are docks on both sides of the river for a thousand feet or more, all of which are privately owned. In 1917 the tonnage was 80,006 tons.

The Clinton River in Michigan, 60 miles long, has a channel eight feet deep and 60 feet wide at its mouth, which narrows down to 50 feet up the stream. The improvement extends for about eight miles up the river and vessels of light draft ascend two miles farther. The lower portion of the Rouge River in Michigan has been widened and deepened for three miles or more from its outlet into the Detroit River up to Wabash Bridge or farther. Its tonnage in 1917 was 1,954,470 tons.

*The Great Lakes and Connecting Waterways.*—Saint Mary's River is the outlet of Lake Superior and flows from Point Iroquois, 63 miles southeasterly, to the Detour Passage into the northern end of Lake Huron. It has a total fall of 18 to 21 feet. Its improved one-way channels are 300 feet wide and 21 feet deep and its bothway or upbound and downbound single channel is 600 feet wide and 21 feet deep. There are four large locks in the Saint Mary's River located at Sault Sainte Marie, Michigan. The Weitzel Lock is 515 feet long and 80 feet wide with a lift of 20½ feet. The Poe Lock is 800 feet long and 100 feet wide with a lift of 20½ feet. The third lock is 1,350 feet long and 80 feet wide with a lift of 20½ feet. A fourth lock is 1,350 feet long and 80 feet wide with a lift of 20½ feet, nearing completion. The Weitzel Lock has a depth of 12 6/10 feet of water on the lower breast wall, the Poe Lock has a depth of water of 18 feet on the lower breast wall, and the third and fourth locks have each a depth of water of 24½ feet on the lower breast walls.

The Saint Clair River connects Lake Huron and Lake Saint Clair. It is 40 miles long. Its channel is from 20 to 22 feet deep and has a width of 400 to 2,400 feet. A channel has been dredged through the Saint Clair Flats, 300 feet wide and 20 feet deep. The distance through Lake Saint Clair traversed by Great Lake vessels is 18 miles, although the lake is 30 miles wide. The outlet of Lake Saint Clair is the Detroit River which is 28 miles long and flows into Lake Erie. It has several channels. Its Fighting Island Channel, four and one-half miles long, is 800 feet wide and 22 feet deep. Its Amherstburg Channel is 12 miles long, 600 feet wide and from 20 to 22 feet deep. Its Livingstone Channel is nine and one-half miles long and has a width of from 300 to 800 feet, and a depth of 22 feet. These are connecting waterways between the Great Lakes. Both the

United States and Canadian canals are open to the vessels of either country.

The Great Lakes with their spacious bays and in-flowing tributaries are partly within the jurisdiction of the United States and partly within the Dominion of Canada. Such parts of them as are within the United States comprise some of its most important waterways. Their waters wash the shores of Minnesota, Wisconsin, Michigan, Indiana, Illinois, Ohio, Pennsylvania and New York. Other States also are brought in touch with their manifold and extensive commerce. Their score or more spacious and improved harbors with the channels of 19 to 23 feet in depth are frequented by the largest grain, ore and lumber fleets in the world, and the volume of their aggregate tonnage approaches, if it does not exceed, 100,000,000 tons annually. They are equipped with all modern appliances for loading and unloading the large lake vessels, some of whose cargo capacities exceed 14,000 gross tons. In 1917, the tonnage at the port of Duluth was 52,411,824 tons, that being the largest tonnage of any inland port in the world.

In 1917 there passed through the United States canals at Saint Mary's Falls, 10,469 lockages of vessels carrying 74,361,850 tons of freight, and 11,990 passengers, and there passed through the Canadian Saint Mary's Falls Canal 5,349 vessels carrying 15,452,048 tons of freight and 26,349 passengers, making an aggregate tonnage passing through the two Saint Mary's Falls canals of 89,813,898 tons of freight and 38,339 passengers. In addition to these were the vessels with their cargoes and passengers passing through other Great Lake ports, but not through Sault Sainte Marie canals. The lake tonnage of the port of Buffalo in 1917 was 18,925,179 tons. Such other lake ports as Superior, Chicago, Milwaukee, Detroit, Toledo, Cleveland, Ashtabula, Corneaut, Erie, Tonawanda, Oswego and Ogdensburg had in the aggregate millions of tons of waterborne freights and in addition thousands of passengers. The commerce of the Great Lakes and connecting waters justifies the expenditure of millions of dollars annually to keep their harbors adequate to accommodate the several hundred lake vessels in the service. The Niagara River along its eastern margin has a ship channel 200 feet wide and 23 feet deep from Buffalo Harbor down five miles through the ship lock 650 feet long and 68 feet wide with 22 feet of water over the mitre sills into the deep waters of the river. The navigable channel at Tonawanda has been improved. Tonawanda Creek is also improved to make it navigable for lake vessels. The harbors and connecting channels of the Great Lakes are from 19 to 23 feet deep at mean lake levels.

Lake Ontario ports include Charlotte Harbor, with a channel, 200 feet wide and 20 feet deep up to the mouth of the Genesee River; Great Sodus Bay and Little Sodus Bay, which have been improved, each having an entrance channel 150 feet wide and 15½ feet deep, protected by lengthy parallel piers; Oswego Harbor with an entrance channel 16 feet deep and 600 feet wide up to the mouth of the Oswego River and Cape Vincent Harbor and the harbor at Ogdensburg. The latter is provided with an upper entrance channel 19 feet deep and from 300

to 450 feet wide, and also for a channel deep and from 200 to 350 feet wide along city water front, and also for a lower entrance channel and basin 19 feet deep and from 2,100 feet wide along the lower frontage. Ogdensburg is the principal Lawrence River Harbor in the United States and its tonnage in 1917 was 1,029,427 tons. Saint Lawrence is the outlet of the Great Lakes and flows wholly through Canadian territory below its Long Sault Rapids a few miles from Ogdensburg.

**Pacific Coast. California.**—The Colorado River is navigable between the Laguna and Fort Mohawk, a distance of 280 miles. Boats of 20 to 22 inches draft nearly all the provided channels be maintained through ing bars of sand. San Diego and Los Angeles harbors have each been dredged and entrance channels 35 feet deep and from 500 feet in width, which channels increase in width landward to turning basins. The tonnage in San Diego Harbor in 1917 was 288,917 tons, and that for 1917 in Los Angeles Harbor was 288,917 tons.

San Francisco has the largest harbor on the Pacific Coast. It is 40 miles long and three to 10 miles wide and its water varies from 40 to 90 feet. It is a locked harbor. It has 50 or more piers averaging 700 feet in length. Its piers for bulk freight are equipped with freight-handling devices. The State of California owns the entire water front of San Francisco. Terminal facilities are publicly owned and open to the public upon reasonable terms. The tonnage in 1917 was 9,294,366 tons. In San Francisco Bay flows Redwood Creek with a channel 150 feet wide and five feet deep and one-quarter mile up stream. There are several wharves. The commerce on this waterway in 1917 was 24,271 tons. Suisun Harbor is but a part of San Francisco Harbor and has a channel 500 feet wide and 3 feet deep at low water through Oakland Estuary, a distance of four and one-quarter miles and thence it is but 30 feet wide and 25 feet deep around the basin 18 feet deep through Oakland Tidal Channel. San Leandro Bay, a further distance of one and three-eighths miles, making a total distance of nine and one-eighth miles. Its tonnage in 1917 was 3,026,279 tons.

San Pablo Bay in California is a waterway 12 miles long and six miles wide with a channel five miles long, 500 feet wide and 5 feet deep. It is provided with 2,000,000 feet of wharves equipped with warehouses and other facilities. Its tonnage in 1917 was 518 tons. Suisun Channel, California, is a waterway 17 miles long with a channel 100 feet wide and six feet deep. In 1917 its tonnage was 62,842 tons. Napa River, California, is provided with a channel 75 feet wide and 10 feet deep, for a distance of 18 miles. It is a tidal estuary with a range of 6.92 feet at low water, giving it 11 feet of water at high tide. Steamers of five-foot draft, carrying fast freight and sailing vessels of six-foot draft, and bulky freight navigate that river, whose tonnage in 1917 was 130,093 tons. Petaluma River, California, a stream 20 miles long emptying into San Pablo Bay, has a channel 600 feet

in its lower section and 80 feet wide in its upper section, having a depth of eight feet of water and is navigable for 16 miles. In 1917 its tonnage was 284,423 tons. Montgomery Harbor in California in 1917 had a tonnage of 248,398 tons.

Humboldt Harbor and Bay, whose entrance is provided with protecting jetties, has a channel 300 feet wide and 18 feet deep. Its tonnage in 1917 was 463,901 tons. The San Joaquin River, California, has a channel nine feet deep and 200 feet wide from its outlet in Suisun Bay to Stockton Channel and through Stockton Channel to Stockton, a distance of 45 miles. That channel is to be extended at the same depth through Freemont Channel and McLeod Lake, which form part of the harbor of Stockton. Another channel, one and seven-tenths miles long, four feet deep and 80 feet wide, is being constructed from Stockton Channel to Centre street in the city of Stockton, known as Mormon Channel. There are several improvements along the river and some terminal facilities. Loaded vessels on that river do not ordinarily draw more than seven feet. The existing project for the improvement of that river provides for the diversion of the waters of Mormon Slough, through a canal, 150 feet wide, to the San Joaquin River. Its tonnage for 1917 was 1,890,856 tons. Mokelumne River, California, is 140 miles long and empties into the San Joaquin River, 20 miles above the mouth of latter. It has a navigable channel 50 feet wide and six feet deep from its mouth to Galt, New Hope Landing, a distance of 35 miles. Its tonnage in 1917 was 78,954 tons. Sacramento River, California, is to have a channel seven feet deep from its mouth at Collinsville in Suisun Bay up to Sacramento, a distance of 60.7 miles, thence a channel of four feet deep up to Colusa, a distance of 90 miles, and thence a channel three feet deep up to Chico Landing, a distance of 51.3 miles, and of such depths as are practicable up to Red Bluff, a distance of 52.4 miles. The latter place is at the head of navigation and 254.4 miles from the mouth of the river. The river points are provided with wharves, warehouses and other terminal facilities. Its tonnage in 1917 was 947,690 tons. Feather River, California, a tributary of the Sacramento, 20 miles above the city of Sacramento, has a cleared navigable depth of two and one-half feet from its mouth at Vernon up to Marysville, a distance of 28.3 miles.

*Oregon, Washington and Montana.*—The Coquille River, 100 miles long, has a controlling depth of five feet and a width of 100 feet from its mouth at Bandon to Coquille, a distance of 25 miles. There are wharves at Bandon and at various points up-stream. The outlet has a depth of 12 feet and the depth of channel decreases up-stream. In 1917 its tonnage was 40,050 tons. Coos Bay has an improved channel 18 feet deep and 200 feet wide up to Marshfield, a distance of 13 miles. Its tonnage in 1917 was 446,062 tons. The Coos River, Oregon, flowing into the bay, has a navigable length of 23 miles. Its tonnage in 1917 was 97,047 tons. Yaquina River, Oregon, has a channel 100 feet wide and 10 feet deep from its mouth to Toledo, eight and one-half miles, and above that town to the head of navigation, 22 miles from the mouth, the channel is 100 feet

wide and two feet deep. Tillamook Bay, which is six miles long and three miles wide, has a navigable channel 16 feet deep and 200 feet wide, and at its entrance it is 22 feet deep. It is protected by a jetty a mile long on the north side. The channel from Bay City up to Tillamook City, 12 miles from the sea, is nine feet deep. The Columbia River is 1,200 miles long. Only 748 miles of its course is in the United States. It flows southwesterly through the State of Washington into the Pacific Ocean between that State and Oregon. It has such large tributaries as the Spokane, the Snake and the Willamette rivers. It has an entrance channel 42 feet deep and one-half mile in width, protected by jetties, the north one being two and one-half miles long and the southern one being seven miles long. The largest Pacific steamships may enter the harbor. The tonnage at the mouth of the Columbia River in 1917 was 2,357,863 tons. A channel 30 feet deep and 300 feet wide is maintained from its mouth up to the mouth of the Willamette River, a distance of 99 miles, and thence up the latter river to Portland, a distance of 14 miles. From the mouth of the Willamette River to Vancouver, Wash., a distance of four and one-half miles, it has an improved channel 150 feet wide and 20 feet deep. It also has a channel 10 feet deep and 300 feet wide in the vicinity of Cathlamet. At Portland on the Willamette are municipal and private docks, which include grain, lumber and other types. At Astoria on the Columbia River is a large municipal terminal and there are many private docks. In 1917 the tonnage was 2,357,863 tons carried on ocean-going vessels and 4,326,681 tons carried on inland river boats. The Cascade Rapids in the Columbia River, 140 miles above its mouth, are overcome by a canal 3,000 feet long with one lock consisting of two chambers, the lower being 469 feet long and the upper one 462 feet long, both of which and the canal have a width of 90 feet and lifts of from 18 to 24 feet, with eight feet of water over the mitre sills. The Dalles Rapids and the Celilo Falls, in a distance of nine and one-half miles, with a total fall of 81 feet, are overcome by the Dalles-Celilo Canal, 190 miles from the ocean, which canal has a depth of eight feet and a width of 65 feet at the bottom and five locks, each 265 feet long and 45 feet wide, with lifts of six and one-half to 70 feet. The canal is eight and one-half miles long. These canals render the Columbia River navigable as far as Priest Rapids, a distance of 397 miles, and also render navigation possible on Snake River to Pittsburgh Landing, which is 540 miles from the mouth of Columbia River. The maximum draft of boats on those sections of the Columbia River is four and one-half feet. The Columbia is to have a channel seven feet deep between Watchee and Kettle Falls, a distance of 242 miles. Pittsburgh Landing, Idaho, on the Snake River, is 216 miles from its mouth and is being improved to secure a channel five feet deep to Riparia, 68 miles above its outlet, and between Riparia and Lewiston, a distance of 72 miles, to secure a channel five feet deep and 60 feet wide, though for much of the distance the channel is from 240 to 700 feet wide. The tonnage through the Dalles-Celilo Canal in 1917 was 57,718 tons. The Willamette, a tributary of the Columbia,

100 miles from the sea, is to have an improved channel six feet deep and 150 to 200 feet wide from Portland to Clackamas Rapids, 11½ miles, and thence a channel six feet deep and 100 feet wide to Oregon City, one and one-half miles, and thence a channel two and one-half to three and one-half feet deep to Corvallis, a distance of 106 miles. The Willamette Falls near Oregon City are overcome by a canal, four locks and a dam. The locks are 210 feet long and 40 feet wide, with six feet of water over mitre sills and having lifts of 10¼ feet. The tonnage through it in 1917 was 113,954 tons. The mouth of the Yamhill River, a tributary of the Willamette, 42 miles above Portland, was formerly the head of navigation, but loaded boats now ascend as far as Harrisburg on the Willamette, 33 miles above Corvallis. The Yamhill, eight miles above its mouth, has a lock 210 feet long and 40 feet wide, with four feet of water over the mitre sills and has a lift of 16 feet. That renders that river navigable to McMinnville, 18 miles above its mouth. Its tonnage in 1917 was 2,032 tons. Loaded boats below Oregon City are of five-foot draft and above that city they are of two-foot draft. The total traffic transported by 31 river boats in 1917 was 491,901 tons. The Lewis River, Washington, a tributary of the Columbia, 26 miles below Portland, divides three and three-quarters miles above its mouth into the North Fork, 106 miles long, and the East Fork, 36 miles long. It has a channel six feet deep and 50 feet wide to the forks. The East Fork has a channel four feet deep and 50 feet wide to La Centre, a distance of three miles, and the North Fork has a similar channel from its mouth to Woodland, a distance of three and one-half miles. Both La Centre and Woodland have terminals publicly owned. In 1917 the traffic on both forks was 25,262 tons, about one-half that of 1916.

The Cowlitz and Gray rivers, Washington, both tributaries of the Columbia River, have been improved in their lower reaches, the former as far as Toledo and the latter for eight miles above its mouth. In 1917 the tonnage on the former was 310,992 tons and on the latter 31,092 tons. Willapa Harbor is at the mouth of Willapa River, which is 30 miles long and is from 200 to 2,000 feet wide at the outlet of the harbor into the ocean. A channel 24 feet deep and 200 feet wide has been constructed from Willapa Bay to the forks of the river at Raymond, and thence up the South Fork, 150 feet wide, to the Cram lumber mill, and also from Raymond up the North Fork, 250 to 350 feet wide, to 12th street. The entire improvement extends 13½ miles. The harbor is equipped with city and railway wharves open to the public use. In 1917 its tonnage was 567,510 tons. Gray's Harbor at the mouth of the Chehalis River is 17 miles long and 14 miles wide and has a channel into it 500 feet wide and 24 feet deep, with projecting jetties, on the south three and one-half miles long and on the north three miles long. The tonnage at that port in 1917 was 455,957 tons. The Chehalis River has a channel 18 feet deep at low water and 200 feet wide from the bay to Cosmopolis, a distance of 15 miles, and thence a channel six feet deep and 150 feet wide to Montesano, a distance of eight and one-half miles. The traffic

on that river in 1917 was 771,480 tons. Into Gray's Harbor also empties the Hoquiam River, whose channel is 100 feet wide and 18 feet deep for a distance of two miles. The commerce on that river is principally lumber.

Puget Sound is a large bay in the western part of the State of Washington opening out into the Strait of Juan de Fuca. It has many connecting arms and extensions, principally to the south and southwest deep waters. Into it flows the Skagit, Snohomish, Snoqualmie, Skykomish, Stillaguamish, Nooksak, Puyallup and Duwamish rivers and connecting navigable sloughs. The conditions are such that permanent results are not obtainable and continuous dredging is necessary. Large vessels may navigate the sound proper, but only vessels of six-foot draft can navigate its in-flowing streams.

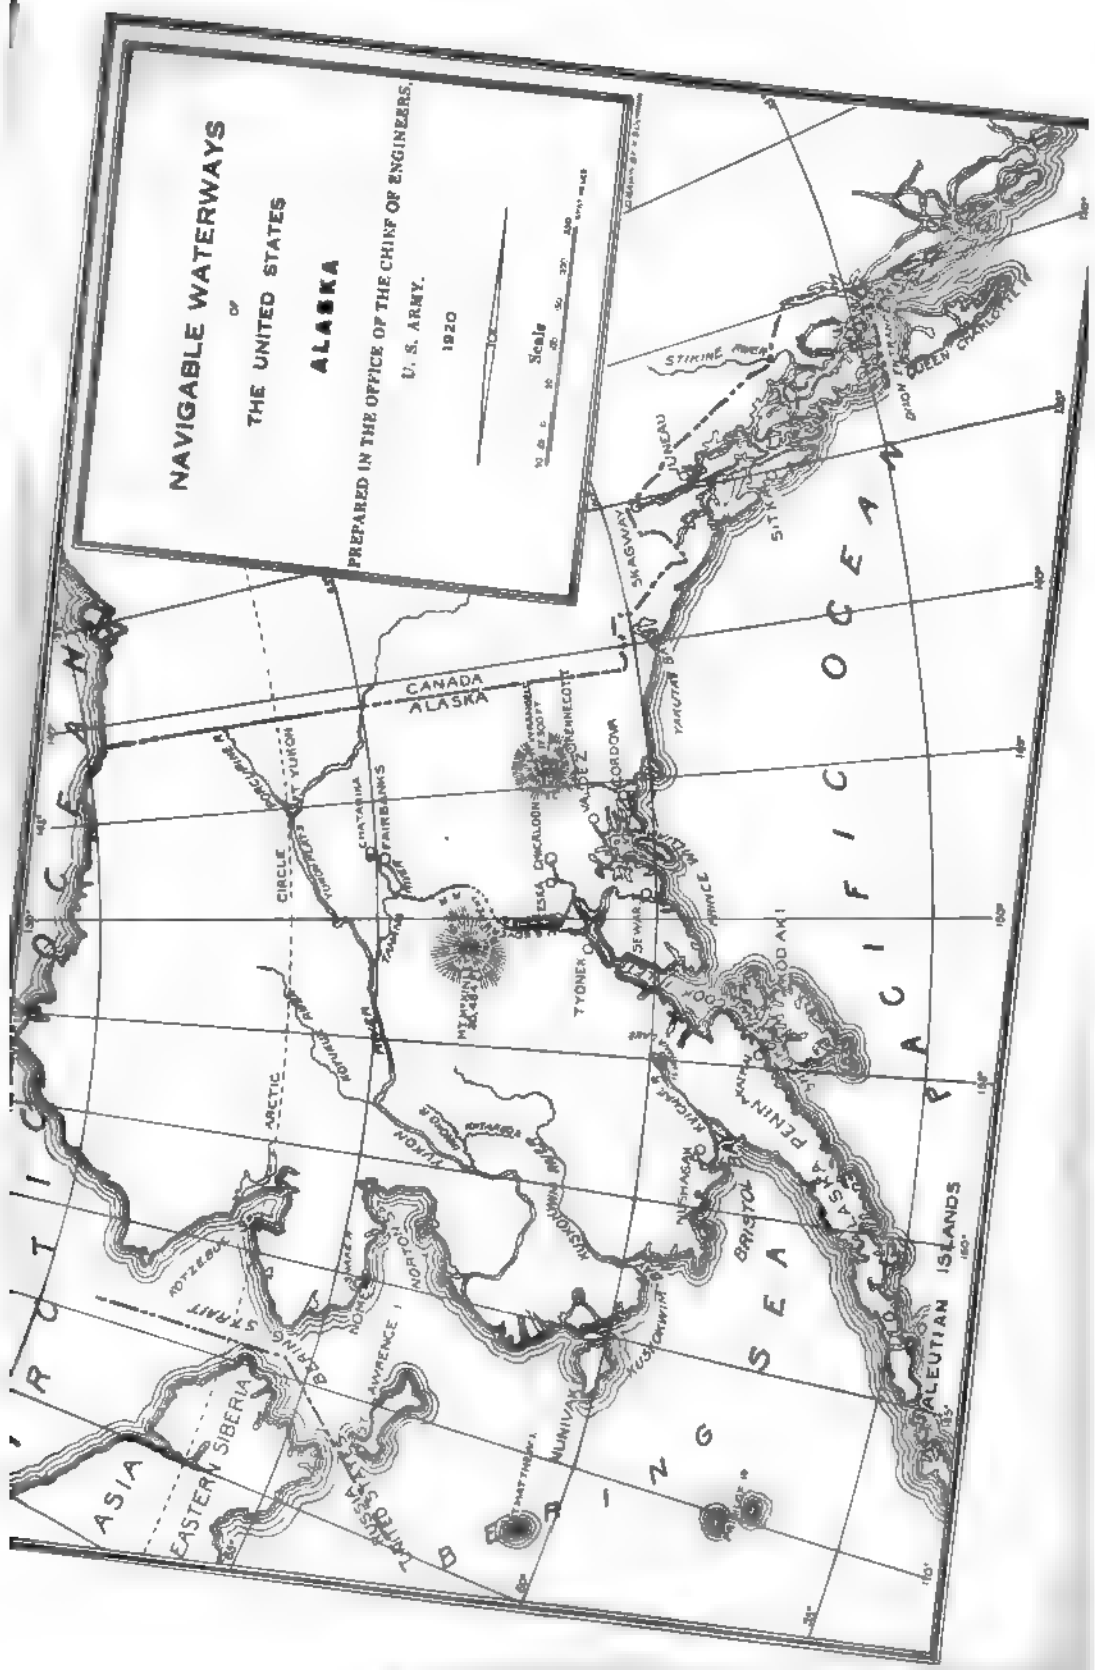

At the south end of the sound is Budd Inlet. Upon this is Olympia Harbor, which has a channel 250 feet wide and 12 feet deep, with turning basins at the end of the improvement 20 feet deep. One of these is 400 feet wide and 800 feet long. The draft of vessels is limited to 10 feet. The tonnage of that port in 1917 was 283,472 tons. Another arm of Puget Sound is Commencement Bay, four miles long and two and one-half miles wide, constituting Tacoma Harbor. That has one channel 500 feet wide and 25 feet deep to 11th street bridge, and thence 18 feet deep to 14th street bridge, and thence from 500 to 200 feet wide and 15 feet deep to a point 8,500 feet from the entrance. The Puyallup waterway has a channel 500 feet wide and 28 feet deep for two-thirds of a mile. That is at the outlet of Puyallup River. The tonnage at Tacoma in 1917 was 2,912,530 tons. Lake Washington Canal extends from the lake through several bays, including Shilshole, Salmon, Lake Union and Union Bays to Puget Sound and is wholly within the city of Seattle. That canal has a double lock 760 feet long and 80 feet wide with 26 feet of water over the mitre sills and a fixed dam. Below the locks to deep water in Puget Sound, a distance of eight miles, the channel is 300 feet wide and 30 feet deep. Wharves and terminals are located on Salmon Bay, Union Bay and Lake Washington. The tonnage at Seattle in 1917 was 4,850,627 tons. Snohomish River has a channel 75 feet wide and eight feet deep for five and one-half miles above its mouth into the Puget Sound and its tonnage in 1917 was 1,038,477 tons. The channel of Skagit River, 150 miles long in the United States, is being improved nine and one-half miles above its mouth across Saratoga Passage. The draft of loaded boats is limited to three feet. Its tonnage in 1917 was 554,797 tons. Swinomish Slough, 11 miles long between Saratoga Passage and Padilla Bay, has a channel 100 feet wide and four feet deep. Its tonnage in 1917 was 54,347 tons. Bellingham Harbor, Washington, is an arm of Puget Sound. It is four miles long and two miles wide. Through its outlet is the Whatcom Creek waterway, 363 feet wide, two-thirds of a mile long and 26 feet deep at the outer end and 18 feet deep for the inner one-quarter mile of the improvement. The draft of loaded vessels was 10 feet. The tonnage of Bellingham Harbor in 1917 was 434,340 tons. The channel in Flathead Lake, Montana, is to have a channel 100

feet wide and six feet deep. Polson Bay at its southern end is a harbor six miles long and five miles wide. Loaded boats there were limited to six-foot draft.

*Alaska.*—Apoon Mouth is the most easterly outlet of the Yukon River and empties into Pastol Bay, 115 miles south of Nome Harbor. The Yukon is navigable for river boats of five and one-quarter-foot draft to the international boundary, a distance of 1,500 miles. Apoon Mouth has been improved for seven miles, having a channel from 150 feet wide and six feet deep through the bars at the mouth. Saint Michael Canal, Alaska, is a salt-water channel 18 miles long, 100 feet wide and six feet deep at the entrance of Saint Michael Harbor. That canal provides a sheltered passage for river boats plying between the port of Saint Michael and the mouth of the Yukon River. The tonnage thereon for the year 1910 was 24,622 tons. Nome Harbor on Norton Sound is the outlet of Snake River, a stream 20 miles long. The harbor is protected by concrete jetties 400 feet long. It has a basin 200 feet wide, 250 feet long and eight feet deep. Its tonnage in 1917 was 17,981 tons.

*Hawaii and Porto Rico.*—Hawaii has Honolulu Harbor, with an entrance channel 400 feet wide, 3,000 feet long and 35 feet deep at mean low water. Since the opening of the Panama Canal Honolulu has become a port of call for coal and fuel oil. It has 22 wharves and piers. Its tonnage in 1917 was 2,037,424 tons. Hawaii also has Kahului Harbor and Hilo Harbor, both improved to a depth of 35 feet. The tonnage of the former in 1917 was 228,853 tons, and that of the latter was 357,406 tons. San Juan Harbor in Porto Rico has an improved channel 600 feet wide and 30 feet deep with terminal facilities. Its tonnage in 1917 was 756,350 tons.

*Cape Cod and Panama Canals.*—The waterways of the United States also include many channels already described and also the Cape Cod and Panama canals. The former extends from Buzzard's Bay to Cape Cod Bay. It is from 100 to 300 feet wide on the bottom and was originally built by private parties, and may become a part of the Intercoastal Waterway from Maine to Key West. It is to be acquired by the United States and be given a prism 30 feet deep, with a minimum width of 200 feet. The largest of the government owned and operated canals is the Panama Ship Canal, approximately 40 miles long, extending from Limon Bay in the Atlantic to La Boca Bay in the Pacific. Its regulated summit level is between 82 and 87 feet above sea-level. The difference is due to the variation in the level of the Chagres River. That level is reached by a double lock, each lift being 45 feet, making a total lift of 90 feet at the Atlantic end of the canal and at the Pacific end there are double lift locks in the Pedro-Miguel section and a single lift lock below Lake Miraflores. Approximately one-half of its length is through Gatun Lake and Lake Miraflores, natural bodies of water, thereby materially reducing the original cost of that waterway. Its locks are 1,000 feet long and 110 feet wide. The canal has a minimum bottom width of 300 feet, but an average width of 649 feet, and it has a minimum depth of 41 feet.

*The Waterways.*—There are other water-

ways not mentioned in this article comprising interior lakes and unimproved rivers. The foregoing enumeration, however, of waterways and the description of their channels are sufficient to indicate their extensiveness the country over as well as their importance to the commerce of the nation. Those hereinbefore mentioned comprise thousands of miles of navigable channels. In their construction and maintenance, the government of the United States has expended hundreds of millions of dollars. Furthermore, some States and many communities have contributed large sums toward waterway improvements. The policy of co-operation between the general government and the States and communities may become a settled policy and that governmental aid may be extended only when localities advance some part of the expense of making waterway improvements. That policy has been adopted in some European countries and has been recommended by one or more commissions of the United States.

The data as to waterborne tonnage given in this article are chiefly from the official records for the year 1917. Over most waterways, it was not as voluminous as it was during the preceding four years, owing to the abnormal conditions prevailing the country over, in consequence of the Great War. Much of the commerce of the country was diverted from waterways to railways, which were under Federal control. The conditions in the year 1918 were still more unfavorable for water carriers and the waterborne tonnage, except ocean traffic, the greatest in the history of the country, was less over inland waterways than it was in 1917.

The end of the war and the return to normal industrial life will awaken an ever-increasing demand for greater facilities of transportation. The waterways of the country will furnish those facilities. The entire Atlantic, Gulf and Pacific coasts, the Great Lakes and the interior waterways of the country are equipped as shown in this article to do a volume of transportation unparalleled at any other period in the history of the world.

*Bibliography.*—Various United States Coast and Geodetic Survey charts; various reports of the Committee on Rivers and Harbors of the House of Representatives of the United States; many Acts of Congress of the United States; the Reports of the Chief of Engineers of the United States army for the years 1900-19; Report of Gen. William H. Bixby, Chief of Engineers, on the Intercoastal Waterway from Maine to Key West; various documents of the House of Representatives of the United States on Waterway Improvement Projects; Reports of the United States Commissioner of Corporations on Transportation by Water in the United States in 1909; Reports of the Mississippi River Commission; Reports of the Ohio River Commission; Reports of the New York State Waterways Association; Reports of the Atlantic Deeper Waterways Association; Reports of the National Rivers and Harbors Congress; Reports of the Tennessee River Improvement Association; Proceedings of the International Joint Commission on Boundary Waters; Report for 1912 of the International Congress of Navigation; Reports of State Engineers of various

States; maps and charts of various sections of the United States; reports of Municipal Harbor Improvement Commissions, and many other records.

HENRY WAYLAND HILL,  
*President of the New York State Waterways Association, author of the articles on "Rain-fall" and "Water Supply" in this Encyclopedia and of "Waterways and Canal Construction in New York."*

**WATERWORKS**, systems of machinery and engineering structures, employed to supply water to individual manufacturing, mining and milling plants, and to municipalities, for domestic and industrial uses and for irrigation. Such systems existed during very early periods of history, and the waterworks of ancient Greece, Carthage and Rome may be readily traced and studied by the ruins of their reservoirs and masonry aqueducts. In these earlier systems, gravity was depended upon for the delivery of the water, but force pumps were introduced about the middle of the 16th century, and extended greatly the general installation and use of waterworks systems. The waterworks built at London Bridge by Peter Maurice 1562 appear to be the first on record. The plant consisted of 16 force pumps, each 17 inches in diameter, and 30 inches long, which were driven by a current wheel, and raised 311,000 gallons of water per day to a reservoir at an elevation of 120 feet above the pumps, and from which the water was delivered by gravity, through lead pipes to buildings in the immediate vicinity.

In the United States, the first pumping plant installed to provide water for municipal purposes was that at Bethlehem, Pa., about 1760. It consisted of a five-inch wooden force pump, which raised water to a height of 70 feet through pipes of bored hemlock logs. This was replaced in 1761 by three single-acting iron pumps, each four inches in diameter, and of 18-inch stroke, operated by an undershot water-wheel. The first municipal water-supply system built in America, however, was that of Boston, in 1652. It was built by the Water-Works Company, and consisted of a reservoir about 12 feet square, to which the water from springs in the vicinity was conveyed through wooden pipes. From 1652 up to the close of the year 1800, the waterworks plants in the United States numbered 16, and had been located and built at the following named cities: Boston, Mass., 1652; Bethlehem, Pa., 1754-61; Providence, R. I., 1772; Geneva, N. Y., 1787; Plymouth, Mass., 1796; Salem, Mass., 1795; Hartford, Conn., 1797; Portsmouth, N. H., 1798; Worcester, Mass., 1798; Albany, N. Y., 1798-99; Peabody, Mass., 1799; New York City, 1799; Morristown, N. J., 1799; Lynchburg, Va., 1799; Winchester, Va., 1799-1800; and Newark, N. J., 1800. With the exception of the plants at Winchester and Morristown, they were all built by private concerns, but passed into the ownership of the respective municipalities from time to time up to 1860. The works at Winchester were built by the municipality, and those at Morristown were built by a private concern and still remain in private ownership. Up to the present time (1919) the number of plants installed throughout the country amounts to nearly 4,000, of which four-fifths are under municipal control.

A clear and concise consideration of the sub-

ject of waterworks may be facilitated ranging the various requirements under general headings—quality of the water; of supply; modes of distribution, and policy.

Quality expresses the fitness of the water for the special purposes for which it may be required. A good quality of water is characterized by freedom from turbidity and color, pleasant taste and odor, and undue sedimentation.

Taste is the first quality to be satisfied in drinking water. Even a perfectly safe water may be rejected because of nausea. This may often be remedied by the addition of chlorine and then removing the chlorine with sodium sulphite.

Turbidity is a condition caused by clay, silt suspended in the water. When the amount of supply is a river, this condition is liable to great variation according to the amount and character of the rainfall over the watershed. Heavy rains of short duration are drained off with great erosive effect, and introduce into flowing rivers vast quantities of finely divided inorganic matter. Such impurity, however, is more offensive than harmful, unless taken into the system frequently or in large quantities. It is removed by the use of settling tanks where the water is allowed to rest and the heavier particles, before it is passed through the filter-beds by which the smaller particles are removed. (See WATER SUPPLY). Color is a condition more offensive to the eye than turbidity to the health. The apparent color is removed by filtration, but true color is removed by oxidation and filtration, but true color is usually due to infusion of vegetable matter, such as leaves, grass, etc., is much more difficult to remove.

Odor is a condition which, although infrequent, is much more objectionable than turbidity or color. As a rule it is due to the life of minute organisms, and is removed to a considerable degree by filtration. It may, however, persist at certain times in the water and has been known to produce, or be associated with, by bowel disturbances among small children.

Sewage contamination is the most harmful of all the various forms of impurities, whether natural or artificial that a water supply may be subjected to, and is the direct cause of such diseases as typhoid fever and various troubles of the intestines, which by undermining the vitality reduces its power of resistance to other diseases. The water may be somewhat purified by filtration, but the proper remedy is to remove the source of pollution. Failing this, the most polluted water may be made reasonably safe for drinking by sterilization with chlorine.

The quality of water is ascertained by various kinds of analyses, physical, chemical and bacteriological. Physical analyses consist merely of comparisons of the given sample with standard solutions, and afford data relative to temperature, turbidity, color and odor. Chemical analyses indicate the time of past contamination and the nature of its origin—whether natural or artificial, and the content of mineral matter. Bacteriological analyses are principally used to ascertain the absence or presence of bacteria, which cause bad taste and odor. Such analyses are capable of showing the number and the probable origin of the bacteria present, but i

ters of differentiation, as in the case of the typhoid germ from the harmless water bacteria, their operation is quite uncertain.

The results obtained by any set of analyses are generally interpreted by chemists and engineers by comparing them with other known facts, without attempting to establish a system of arbitrary standards. A minimum limit of impurity, however, may be stated, as follows:

(1) The best authorities consider water as unfit for drinking purposes when 100,000 parts of the liquid contain more than three parts by weight of mineral matter or one part by weight of dry organic matter, before it has been submitted to precipitation, or when it holds in suspension more than one part by weight of dry organic matter after six hours of perfect repose in a reservoir.

(2) When the same amount of liquid contains in solution more than two parts by weight of organic carbon, or three parts of nitrates.

(3) If it exhibits a distinct color under daylight when placed in a white porcelain dish, to the depth of one inch.

(4) When 100,000 parts of the liquid contain more than two parts by weight of a salt of any metal except calcium, magnesium, potassium and sodium.

(5) When 100,000 parts of the liquid contain in solution, suspension, or chemical combination, more than 0.5 part of arsenic.

(6) When 100,000 parts of the liquid, after the addition of sulphuric acid, contain more than one part by weight of free chlorine.

(7) When 100,000 parts contain more than one part by weight of sulphur in the form of sulphuretted hydrogen, or a soluble sulphuret.

(8) When 100,000 parts of the liquid holds in suspension more than 0.5 part of petroleum or hydrocarbon, or exhibits a film of the same upon its surface.

(9) When the acidity is greater than that produced by two parts by weight of hydrochloric acid to 1,000 parts of distilled water.

(10) When the alkalinity is greater than that produced by adding one part by weight of caustic soda to 1,000 parts of distilled water.

(11) When 10 cubic centimeters of water contain more than 100 harmless bacteria. This is the requirement of the government for water served on railroad trains in interstate commerce, and is adopted by all bottlers of table waters.

In general, a large percentage of chlorine and nitrates, together with the presence of *Bacillus coli communis*, an organism originating in large quantities in the human intestines, indicate sewage contamination.

A very simple but reliable test for sewage contamination was suggested by Heisch. To half a pint of the suspected water placed in a clear colorless glass-stoppered bottle, add a few grains of the best white lump-sugar, and expose the bottle freely to daylight in the window of a warm room for a week or 10 days. If the water remains clear it may be considered safe, but if it become turbid, it is open to grave suspicion of sewage contamination.

Turbidity or a precipitate which follows upon the addition of baryta water indicates the presence of carbonic acid; chloride of barium is used in the same way as a test for sulphates; nitrate of silver for chlorides; oxalate of

ammonia for lime salts; sulphide of hydrogen, slightly acid, for salts of antimony, arsenic, bismuth, calcium, copper, gold, lead, mercury, platinum, silver and tin; an alkaline (by ammonia) solution of sulphide of ammonium, for salts of aluminum, chromium, cobalt, iron, manganese, nickel and zinc. Chloride of gold or mercury and the sulphate of zinc are the reagents for organic matter.

Hardness of water is a quality that bears chiefly upon its use for boilers and for laundry purposes. The hardening impurities are principally the salts of lime and magnesia. Their carbonates produce temporary hardness which may be removed by boiling, when the carbonic acid is dissipated and the insoluble bases are deposited as incrustations on the bottoms of the kettles and boilers. The carbonates are less troublesome to the human constitution than to steam users, but the sulphates, chlorides and nitrates of lime cannot be dissipated by ordinary boiling and are productive of what is known as permanent hardness. Ordinarily pure water can take up only about two grains of carbonate of lime per imperial gallon of 70,000 grains, but when carbonic acid is present, that amount of water will dissolve as much as 20 grains of the carbonate. The degree of hardness is estimated according to the number of grains of soap the solution is capable of neutralizing. Thus, one, two and three degrees of hardness represent the neutralization of 10, 20 and 30 grains of soap, respectively. The amount of waste, in the wear of clothes and soap, and the destruction of many valuable food properties by the use of hard water is not fully appreciated by the general public. It is safe to state that the money value of that waste far exceeds the cost that would supply an abundance of water for domestic purposes from a source free from impurities.

Systematic processes for softening water have been employed in the United States, principally in connection with manufacturing plants. The first process was invented by Prof. Thomas Clark, of Aberdeen, Scotland, in 1841, and consists of mixing the water supply with lime water or milk of lime, and allowing it to subside for a period ranging from 12 to 24 hours, when the water is drawn off while the precipitate is left behind. The first softening plant in connection with a municipal water supply in America is that connected with the waterworks of the city of Winnipeg, Manitoba. The source of supply is a number of artesian wells, and the water obtained is very hard. The softening process employed is a modification of that of Clark, and includes a variety of settling and filtering devices, into which the water is pumped and mixed with the lime solutions and then drawn off and distributed by direct pressure pumping into the mains. Its working provides a water more beneficial to the health, and better for domestic purposes, than that of the Red River, which formed the original water supply of the city. (See WATER SOFTENING).

While boiling is a very cheap and thoroughly effective process of purifying water, and may be used by householders in general, distillation, owing to its expense, may be employed only in special cases, in connection with artificial ice plants, the conversion of salt water into fresh water at sea, and in the various industrial arts.

It will be noted, however, that both boiled and distilled water are unpalatable unless aerated before used for drinking.

Sources of water supply will be found extensively treated under that title. In a general way, the origin of all sources is the atmosphere. It is a simple matter to trace the course of the water from the clouds in the form of rain to the rivulets which form the feeders to the lakes and rivers, and which, percolating through the porous rocks and earth, issue as sparkling springs along the valleys. Some special suggestions, however, relative to the selection of a potable water is advisable in this connection. In the open country water reaches the ground in a fairly pure condition and by selecting a site isolated from the drainage of barnyards, house sewerage and fertilized gardens, an excellent quality of water may be obtained from a well. Extending the application to where the supply is for the use of a community, town or small city, subterranean reservoirs in which the great rain percolations are stored up, may be tapped by artesian wells and furnish an inexhaustible supply of pure water. In boring these wells, however, a thorough knowledge of the geological structure of the region is important (see ARTESIAN WELLS), in order to avoid unsuccessful and costly boring operations, as well as to obtain a sufficient quantity of water free from sub-surface impurities. Waters percolating through or over the crevices of granite, gneiss, serpentine, trappean, mica-slate or silicious sandstone and drift formations, are usually quite pure, since the disintegrations of such formations are not soluble in pure water. On the other hand, limestones and chalks impart objectionable qualities. Carboniferous rocks are often composed largely of mineral salts and the water penetrating such strata are of a briny nature and are wholly unfit for domestic use. This is the case in the Kanawha Valley and in some parts of Ohio, West Virginia and the State of New York. In the bituminous limestones of the oil regions of Pennsylvania, the waters passing through those strata are saturated with petroleum compounds, while the dark waters issuing from the sulphurous rocks of the Niagara group of the Ontario geological division carry a high percentage of sulphuretted hydrogen.

As the municipality requiring the water increases in size, the quantity obtainable from a source of supply becomes more and more important. The per capita consumption varies greatly and very often quite unexplainably. See WATER SUPPLY.

In the ancient cities of Jerusalem, Rome, Byzantium and Alexandria, the consumption amounted to 300 gallons per capita, daily.

In 1870, the water consumed by the principal European cities, in gallons per capita, was as follows: London 29, Liverpool 27, Glasgow 40, Paris 30, Marseilles 40, Genoa 30, Geneva 16, Madrid 16, and Berlin 18. On the other hand, it is not an unusual thing to find American cities consuming all the way up to 300 gallons per capita, the largest consumption being in the irrigation districts and in manufacturing towns. Without doubt, a great amount of the water in such cases is really wasted, but American hydraulic engineers in planning for a water supply under the present conditions, calculate

upon the basis of a consumption of 100 per capita, with provisions to meet demand in the near future.

A fair average daily consumption may proximately estimated as follows, in gallons capita, on a basis of total population: 1 ordinary domestic purposes, 20 gallons; private stables, including carriage washing, 16 gallons; commercial and manufacturing use, 10 gallons; fire protection, 0.2 gallon, hose and sprinkling of streets and grounds, during the four or five driest of the year, 10 gallons; waste to prevent freezing of water in the service pipe, house fixtures in northern cities, during three coldest months of the year, 10 gallons; and waste by leakage, and for flushing, 10 gallons; a total of about 80 gallons. Actual domestic consumption has been estimated by meters to range from eight gallons capita in a one-family apartment with bath and one toilet, to 46 gallons per capita in a crowded boarding house.

Thus for the larger cities, the selective source of supply passes from wells and to the large ponds and lakes. Importations of such are found in the city of Chicago and Milwaukee, which draw supply from Lake Michigan, and Cleveland and Buffalo, from Lake Erie. In the major cases the principal cities of the world obtain their water from rivers, although a great as in the case of New York, which draws supply from Croton Lake and the watershed of the Catskills, have adopted natural basins and converted them into artificial means, such as dams, etc., into reservoirs, fed solely by the rainfall of the drainage area. In such cases the principal of delivering the supply at the point of consumption is by gravity, through (q.v.), connecting the source of supply with distributing mains. Intermediate storing filtering reservoirs may be employed in connection with the source of supply to equalize the conditions of turbidity, color, etc., inherent to surface waters, while at pumping stations may be built and open connection with standpipes if any part of the area using the water happens to be higher than the level of the source of supply. See

On the other hand, when a river is the source of supply, its natural position at the lowest part of the valleys compels the elevation of its waters before delivery to the consumer. This is accomplished by pumping plants which raise the water into reservoirs or standpipes from which it is distributed by gravity. In either case, in planning a system of water works, it is essential that proper provision be made to insure a pressure of delivery constant and adequate to supply the consumption per capita for all domestic and industrial purposes, and of sufficient power to traverse streams over the tops of ordinary hills. A combination of the gravity and pumping systems is employed by the city of Washington. From the Great Falls of the Potomac, several miles west of the city, the water is conveyed through a conduit to receiving reservoirs on the heights adjacent to the city and distributed

period of subsidence, is passed into the distributing reservoirs and thence to the service mains. Certain portions in the northwestern and northeastern parts of the city being higher than the receiving reservoir, pumping stations connecting with the distributing mains pump the water into standpipes in the elevated sections, from which it is delivered to the consumers by gravity. As a rule, the cost of establishing pumping systems to lift the water from the river from a point near at hand to the standpipes, is far less than that of building the necessary aqueducts to conduct the water from a point on the river a sufficient distance beyond to insure the required head or pressure. In the case of Washington, however, the arrangement is practically necessary since the sewage of the city flows into the river in the immediate vicinity, and the current of the river itself is affected by the ebb and flow of the tide to some distance above the city, so that the water immediately at hand is in a polluted condition. In this connection it may be mentioned that but a very small number of American cities are fortunate enough to obtain an abundant supply of water directly from natural sources sufficiently transparent and limpid for domestic purposes. The great majority are compelled to resort to artificial means of various kinds, such as storage and settling reservoirs, filter beds, sterilizing basins, and pumping plants, to insure the purity and quantity required. In the light of the present knowledge of the ease with which water of a considerable degree of pollution may be sterilized with chlorine, no water-supply plant is complete without this cheap safeguard.

The character of "pumping plants" varies according to the source and mode of supply, the motive power employed and the working pressure on the pumps. In connection with the source and mode of supply, such plants are arranged for direct pumping, or for pumping into a reservoir. Direct pumping plants are liable to be affected by great and sudden changes in working pressure and, therefore, require machinery capable of responding quickly to such changes, with strong and simple working parts automatically regulated under variable speeds. On the other hand, since the machinery employed to pump into a reservoir works against an almost constant head or pressure, at a practically uniform rate of speed, a much greater latitude is presented in the economy of design and operation.

As a general rule, when the source of supply is more than 25 feet below the surface of the earth, economy in the matter of excavations and foundations compels the use of some form of a vertical rather than a horizontal pump. If the well is very deep two sets of pumps, one at the bottom and one at the surface, may be employed, or by the use of the air lift, the motive power may be kept at the surface of the ground. On the other hand, when the water has to be pumped from a river to a settling reservoir for purification, and then repumped into the distributing mains, under conditions involving a comparatively low lift, some form of horizontal or centrifugal pump is the most suitable. See PUMPS AND PUMPING MACHINERY.

Relative to motive power for the pumping plant, it is evident that water power, when it can be obtained in a sufficient amount, is the

ideal source of energy, since it is generally inexhaustible and always cheap. If, however, it cannot be obtained during the whole year, it may be supplemented by steam or electric power, or by a system of storage reservoirs arranged to equalize the flow of the stream under the varying conditions of wet and dry seasons. The employment of steam, electric and compressed air power to operate pumping plants depends to a great extent upon the cost of fuel used. When the pumping plants are situated at points far from the fuel supply, they may be operated frugally, within the limits of economical electric power transmission, by power derived from dynamos driven by steam-engines or the energy of waterfalls. The high-pressure hydraulic pumps are exceptionally economical and efficient where sufficient head is available. Compressed air may be used to operate small plants located at a distance from the main plant, and also to operate air lifts where deep wells are the source of supply, while oil and gas engines are the most economical for operating isolated secondary pumping plants in large cities, or the main pumps of small towns and villages. It is a fact, however, that in a majority of the waterworks throughout the world, steam is the motive power employed, the pumping engine usually combining the motive power and pump action in one machine. They are of several different types, and the adoption of any particular one depends practically on the cost of the fuel used. When that cost is great, high duty engines, although more expensive in design and construction, but capable of performing a relatively larger amount of work with a small amount of fuel, are adopted. See PUMPS AND PUMPING MACHINERY.

For specific information on the construction of reservoirs, filter beds, tanks and standpipes see WATER SUPPLY.

Standpipes placed upon the force mains are employed by several American cities, whose reservoirs are distant from their pumping stations to equalize the resistance against the pumps. Those at Louisville, Milwaukee and Saint Louis are examples. Other cities, such as Chicago and Toledo, where proper reservoir sites are unattainable, use open-topped standpipes of considerable height, ranging from 150 to 275 feet. They serve as partial substitutes for relief valves acting in conjunction with tall air chambers. In the standpipes the surface of the water rises and falls according to the rate of delivery into them by the pumps and the rate of draft when the main over which they are placed is connected with the distributing system. In northern cities they have to be housed to prevent the water from freezing during the winter.

The water obtained by any of the methods already described is supplied to the consumers by distributing systems comprising the various kinds of mains, service pipes, house fixtures, valves and hydrants which control the flow and the delivery of the water, while various kinds of meters record the amount consumed and afford a basis for taxation. See WATER METERS.

Such systems usually consist of one or more trunk mains from which numerous branch pipes, continually diminishing in size, lead under the surface of the streets and connect with the various buildings. The mains are usually of cast iron, although wooden pipes have

been and are even at the present time used under certain conditions. Under a direct pressure system, when the water is pumped through such a pipe it is called a force main. Originally they were of wrought iron, but proving unreliable were superseded by cast iron and finally by those of riveted steel. See PIPE, MANUFACTURE OF.

The size of trunk mains depends upon the required volume and velocity of the water conveyed and vary from 48 to 72 inches in diameter. Pipes leading to fire hydrants should not be less than four inches in diameter, and when of that size should be restricted to lengths not exceeding three or four hundred feet and leading to a single hydrant. Service pipes are usually of lead or wrought iron. Lead pipes, although more expensive, are preferable on account of their flexibility, smooth interior surface, great durability and relative non-corrosiveness. Plain wrought-iron and galvanized-iron pipe corrodes so rapidly that it is unfit for use unless coated both inside and outside by asphaltum or varnish of some kind. Various substances have been applied for that purpose from time to time, while interior linings of cement have been used extensively; but the present practice is confined to the application of an asphaltum bath, with perhaps the most satisfactory results obtainable. It consists simply of a mixture of coal tar and asphaltum in proportions that will give a coating non-brittle at the freezing point.

Valves are employed to control the water as it flows into the mains and from them into the service pipes. Pipes are always liable to accident through excavations for buildings, sewers, electric conduits, overflows and quicksand and clay slides. It is also very often necessary to shut off the water when new hydrants are attached, or when large pipe connections or repairs are made. Under such circumstances means to maintain a constant supply at and beyond the points involved are best obtained by a duplicate arrangement of sub-mains in parallel lines at several squares distance, joined across by a system of smaller service mains, so that there are always at least two lines of sub-mains around any given point. Under such conditions stop-valves may be used with advantage to shut off the water from a particular point without cutting off the supply from what may be a large territory lying beyond. Stop-valves are made in a great variety of forms, but the best have double self-adjusting discs, with the seats slightly divergent, so that the pressure of the screws sets the valve-discs snug upon the seats. They are usually located on the mains under some unvarying system as, on the property line of the block and five feet from the curb, on the southwest corners of street intersections. Thus they may be readily found in case of accident when hidden by a cover of frozen earth, snow, or other debris. Blow-off and waste valves are attached to pipes laid upon undulating ground, and are used to flush out the sediment deposited by the water, in the principal depressions of mains and sub-mains. Their diameters are usually about one-half that of the mains from which they branch and they may be led into sewers or wherever the waste water may be disposed of. Valves commonly known as corporation cocks regulate the flow into the houses and are usually set in the sidewalk near the

curb. Check-valves act against a backward flow of water and are useful on force mains to protect the meters against back pressure, while reducing-valves are employed to relieve depressed areas of a city from excessive pressure where an effective division into high and low service is impracticable. They operate automatically, under the hydraulic pressure in the mains in which they are located, while the other forms are operated by hand or may be operated by electrical connections. Valves are expensive contrivances, and the cost of the larger sizes may be often reduced by the application of the Venturi principle, the larger pipes being gradually contracted to the size of a small valve, and then gradually increased to the original size without much loss of pressure.

Hydrants are valves used for fire-fighting and flushing purposes. In post or fire-hydrants, a vertical tube extends from the valve to a certain height above the ground. They are usually set on a branch pipe, at or near the curb line, and may be provided with from one to four nozzles, according to the capacity of the service mains, for the attachment of fire-hose. They are made in an innumerable variety of patterns; a first-class hydrant, however, consists of a frost case that is free to move up and down as the ground expands and contracts under varying temperatures, without straining the hydrant base; a waste-valve that will drain the hydrant effectually as soon as the main valve is closed, and which will close automatically as soon as the main-valve begins to open; a main-valve that is positively tight, which if it closes "with" the pressure will be free of any slack motion of its stem and thus prevent a severe water-ram at the moment it is closed; a screw motion of the valves requiring at least 10 complete revolutions before the valves are seated, thus insuring a slow closing and preventing the excessive shock and strain on the valves of an entire system that may result from a water-ram caused by the simultaneous closing of several hydrants. A stop-valve is usually placed between the main and the hydrant, so that the latter may be repaired without shutting off the flow through the mains. Hydrants should not be placed more than 500 feet apart, while in a closely built business district they may be placed at very near intervals.

Waste by leakage from the mains and poorly constructed flushing devices varies from five gallons upward per capita, and its reduction to a minimum is essential to the economical operation of any system of waterworks, but it is especially important when the service is by pumping, for the cost of pumping the waste is proportionally equal to that which is actually used. This is true also when the source of supply is distant and the purity of the water depends upon the conservation of its quantity. This can only be accomplished by careful workmanship in the construction of the plant; careful pipe laying; the use of high-grade, self-closing plumbing fixtures, especially those devices used for flushing water-closets and the installation of meters not only to detect leaks and other causes of waste in the houses, but to form the basis for charges against the consumer and compel carefulness on his part. This, however, brings the matter to a point where it is necessary to harmonize good practice with

public policy. The details of district meter systems and the inspection of service pipes are minor problems as compared with the equitable adjustment of water rates according to the various classes of consumers. In general, although the district plan is but a poor competitor of the house meter system, it has produced good results in controlling waste and detecting leaks whenever it has been employed. See **HYDRAULICS**; **HYDROSTATICS**.

K., 'Water Supplies: their Purification, Filtration and Sterilization' (London 1914); Turneaure, F. E., and Russell, H. L., 'Public Water Supplies: Requirements, Resources, and the Construction of Works' (New York 1913); Uren, F. C., 'Waterworks Engineering' (Bristol 1914); Wegmann, E., 'Conveyance and Distribution of Water for Water Supply' (New York 1918).

**WATIE, Stand**, Cherokee Indian leader and soldier: b. Oo-yoo-ge-lo-gi, near the present town of Rome, Ga., about 1806; d. 2 Sept. 1871. His father, Oo-wa-tie, was a Cherokee of pure Indian blood and his mother was the child of a white father and a Cherokee mother. His given name was Degataga, which, rendered into English, signified "standing together," whence came his English given name, Stand. His surname was a contraction of his father's given name. Elias Boudinot, known also as Buck Watie, was an elder brother of Stand Watie. Major Ridge was his uncle. In common with his immediate kinsmen, Stand Watie was active in his support of the removal treaty and was marked for assassination at the same time they were but was warned in time to save himself. He was thenceforth regarded as the head of the Ridge, or the Forty Party in the Cherokee Nation. At the outbreak of the Civil War, he espoused the cause of the seceding States, raised a regiment for the Confederate service, commanding it with the rank of colonel until May 1864, when he was promoted to the grade of brigadier-general. The end of the war found him homeless and penniless. His brave struggle with adversity was ended by his death.

**WATKIN, wôt'kin, Sir Edward William**, English railway manager: b. Northenden, Cheshire, 1819; d. London, 14 April 1901. He was engaged in the warehouse of his father, a London merchant, from 1829-45 when he became secretary to the Trent Valley Railroad Company, and thenceforward continued in the railway business, becoming general manager and director in various leading companies. He was chairman of the Southeastern in 1867 and of the Metropolitan in 1872, extricating each from financial difficulties. While president of the Canadian Grand Trunk he prosecuted negotiations which resulted in the confederation of the five British North American provinces. He was elected to Parliament for Great Yarmouth in 1857, but was unseated by petition. In 1864-68 he was a member for Stockport and for Hythe in 1874-95. He was knighted in 1868, and created a baronet in 1880. He was the chief promoter of the Channel tunnel project.

**WATKINS, wôt'kinz, John Elfreth**, American scientist: b. Ben Lomond, Va., 17 May

1852; d. 1903. He was graduated from Lafayette College in 1871, and until 1872 was mining engineer for the Delaware and Hudson Canal Company. He was appointed curator of the United States National Museum in 1877, an office he occupied until 1892, and in 1895 became superintendent and curator of its technological collections. He wrote much concerning the development of railroad and telegraph systems, including 'The Evolution of the Railway Passenger Car' (1888); 'History of the Pennsylvania Railroad, 1846-96' (1896), etc.

**WATKINS, N. Y.**, village, county-seat of Schuylcr County, on Seneca Lake, and on the New York Central and Hudson River (Fall Brook) and the North Central railroads, about 20 miles north of Elmira. It is in an agricultural region in which are large vineyards. The Glen Springs Sanitarium is a famous salt plant, but the chief attraction is the glen. The principal manufactories are flour and lumber mills, wagon and carriage factories and iron foundries. Several mineral springs are nearby. Large quantities of grapes are shipped in the season. The village has a high school, founded in 1863, graded schools, two libraries, two private banks and three newspapers. Pop. 2,760.

**WATKINS GLEN, N. Y.**, near the village of Watkins, in Schuylcr County, a ravine noted for its picturesque scenery and its great beauty. The rocks are Devonian shale, which, during the Pleistocene period, were cut into narrow gorges by the glacial ice. The gorge here is, in places, 300 feet deep, and a narrow stream flows through, forming a succession of beautiful cascades and rapids. On the slope from the crest of the elevation overlooking a most charming part of the gorge, to the village of Watkins, is a cemetery, which for natural beauty is rarely equaled. The artist, Hope, made Watkins his home for many years, and he was laid to rest in the cemetery he so much admired. Many tourists visit the glen each year.

**WATKINSON, wôt'kin-sôn, Davil**, American philanthropist: b. Lavenham, Suffolk, 17 Jan. 1778; d. Hartford, Conn., 13 Dec. 1857. He came with his parents to the United States in 1795 and was for a time engaged in a New York counting-house. He established a business in Hartford with his brother William in 1800, and retired in 1841 with an immense fortune. His will bequeathed large sums to various charitable institutions and he also gave \$100,000 to the Connecticut Historical Society for a reference library.

**WATLALA INDIANS**, a tribe of the Chinookan stock of North American Indians, who call themselves Kwikwulit, and who have also been known as Upper Chinook, Wahclallah, "Dog River, or Cascade Indians," etc. They formerly occupied the Cascades and about the Dog River, which discharges into the Columbia about midway between the Cascades and The Dalles, in Wasco County, Oregon. They numbered but 80 souls in 1854; in the next year they entered into the Wasco treaty, by which they agreed to move to the Warm Spring Reservation, where a few of them now are, while the others are still about the Cascades. Their language is almost identical with that of the Wasco Indians (q.v.).

**WATLING** (wōt'ling) **STREET**, England, one of the great Roman roads, beginning at Dover, passing through Canterbury and Rochester to London and thence to Chester and York, and north in two branches to Carlisle and the Wall in the neighborhood of Newcastle. Traces of the ancient road are still found in many parts of its course, and in some it is still an important highway; a street in London retains its name. It was the line of division in the treaty between Alfred and Guthrum the Dane, and it is still the boundary between Warwickshire and Leicestershire. Of the origin of Watling nothing is now remembered; it was formerly written Wæclinga Stræt, and is supposed to be a corruption of Stratum Vitellianum; a trace of the title survives in the name Wattlesborough, a place on Watling street near Wroxeter (Uriconium).

**WATLINGS** (wōt'lingz) **ISLAND**, one of the Bahamas, British West Indies, lying 220 miles northeast of Cuba. It is 18 miles long and has a lagoon near the centre. It is fertile, but sparsely inhabited. It is now generally admitted to be the first landing place of Columbus called by him San Salvador. Pop. about 617.

**WATMOUGH, James**, United States naval officer: b. Whitemarsh, Pa., 30 July 1822; d. Washington, D. C., 18 Jan. 1917. He was educated at the University of Pennsylvania, and from 1843-44 was acting midshipman. He served in the Mexican War, and participated in the capture of California. In the Civil War he commanded the South Atlantic Squadron and took an active part in the operations on Stone River and James and John Islands. Later he became general pay inspector of the navy, and from 1873-77 was paymaster-general. In 1884 he was retired and in 1906 was created rear-admiral.

**WATROUS, Harry Wilson**, American artist: b. San Francisco, Cal., 17 Sept. 1857. He studied at Atelier Bonnat and at Julien Academy, Paris, and later established himself in New York. He specializes in studies of city life, his paintings being usually of a small size, exquisitely finished and occasionally of somewhat daring conception. He was married to Elizabeth Nichols, also an artist, in 1887. Among his works are 'Passing of Summer' (Metropolitan Museum, New York); 'An Auto Suggestion' (Buffalo Fine Arts Academy); 'A Study in Black' (Saint Louis Museum), and many works in private collections.

**WATSEKA**, wōt-sē'ka, Ill., city, county-seat of Iroquois County, on the Iroquois River, and on the Chicago and Eastern Illinois and the Toledo, Peoria and Western railroads, about 75 miles south of Chicago and 100 miles east of Peoria. It is in an agricultural and stock-raising region. The chief manufacturing establishments are flour and grist mills, planing mills, knitting mills, brick and tile works and machine shops. There are seven churches, public elementary schools, two banks and two newspapers. Pop. about 2,476.

**WATSON, Alfred Augustus**, American Protestant Episcopal bishop: b. New York, 21 Aug. 1818; d. 21 April 1905. He was graduated from the University of New York in 1837, studied law and in 1841 was licensed to practise in the New York Supreme Court. He then

turned his attention to theology, and took priest's orders in the Episcopal Church. During the Civil War he served as chaplain in the Confederate army, and in 1884 was consecrated bishop of East Carolina.

**WATSON, Clarence Wayland**, A. legislator: b. Fairmont, W. Va., 8 May 1852. He was educated in the public schools of Marion County and since his youth he engaged in coal mining in West Virginia. He organized several companies which were consolidated as the Consolidated Coal Company, with mines in West Virginia, Pennsylvania and Kentucky, of which he was president until 1911, and since served as a man of the board. He is interested in other industrial and financial establishments. Mr. Watson was delegate to the Democratic National Convention at Denver in 1908 and 25 Jan. 1911 was elected United States senator from West Virginia, for the unexpired term of the late S. B. Elkins. Senator Watson served on the Democratic National Council since 1916. On 25 March 1918 he was commissioned lieutenant-colonel and was detailed to the Ordnance Department.

**WATSON, David T.**, American lawyer: b. Washington County, Pa., 2 Jan. 1832; d. 1916. He was graduated from Washington Jefferson College in 1864, studied law at the University of Pennsylvania, and was admitted to the bar for two years, was admitted to practice in Pennsylvania. In 1903 he was chosen as the three counsel for the United States to the Alaskan Boundary Commission. He prepared an important brief for the government in cases against the Standard Oil corporation about 1909.

**WATSON, Elkanah**, American agriculturist: b. Plymouth, Mass., 22 Jan. 1758; d. Kent, N. Y., 5 Dec. 1842. He was apprenticed at 15 to John Brown of Providence, one of the famous mercantile firms, and was intrusted by him with \$50,000 to be invested in cargoes for the markets of Europe. He made the journey to Charleston successfully, his journal, subsequently published, is the existing account of the principal towns and colonies at the time of the Revolution. He opened a branch house in Nantes, France, in 1779, meeting with much success for three years when he lost his property through the French finances. He returned to America in 1784, engaged in trade between South Carolina and Haiti until 1788, and in 1789 returned to Albany, where he was an active promoter of public enterprises. He projected and was instrumental in the construction of a canal for New York State, founded the Bank, organized the first agricultural society in New York, aided the establishment of the Erie canal, and was an earnest worker for improved educational advantages. He published 'Tour in Holland' (1790); 'History of Western Canals in the State of New York' (1820); 'History of Agricultural Society' (1820). Consult Watson, Winslow, C., and Times of the Revolution, or Memoirs of Elkanah Watson' (1855).

**WATSON, George Lennox**, English architect: b. Glasgow, 30 Oct. 1851; d. 1904. After a five-years' connection with shipbuilding firms he established

in Glasgow in 1872 as a naval architect. His first success was made in 1873 with the racing yacht *Clotilde*. Subsequently he designed more than 400 vessels, including, besides racing yachts, passenger, mail and cargo steamers, and some of the largest steam yachts afloat. Among his racing yachts were *Vanduara* (for John Clark of Paisley); the cutter *Britannia* (for the Prince of Wales, later Edward VII), and the *Thistle*, *Valkyrie II*, and *Valkyrie III*, competitor's for the *America's* cup.

**WATSON, Henry Breerton Marriott**, English novelist: b. Caulfield, Melbourne, Australia, 20 Dec. 1863. Graduated from Canterbury College (Christchurch) in 1883, he went in 1885 to England, where he took up journalism in 1887. He wrote much for the *National Observer* and was assistant editor of *Black and White* and the *Pall-Mall Gazette*. Among his works are 'Marahuna' (1888); 'The Web of the Spider' (1891); 'The Adventurers' (1898); 'The Skirts of Happy Chance' (1901); 'The House Divided' (1901); 'Godfrey Merivale' (1902); 'Alarms and Excursions' (1903); 'The Block House by Bull's Ferry' (1904); 'At a Venture' (1911), and 'Chapman's Wares' (1915). With J. M. Barrie he was joint-author of the drama 'Richard Savage.'

**WATSON, James Craig**, American astronomer: b. Fingal, Ontario, 28 Jan. 1838; d. Madison, Wis., 23 Nov. 1880. He was graduated from the University of Michigan in 1857, was appointed professor of astronomy there in 1859, and in 1879 accepted the chair of astronomy at the University of Wisconsin. He accompanied the eclipse expeditions to Iowa in 1869 and to Sicily in 1870, and was in charge of the expedition to Peking, China, for the observation of the transit of Venus in 1874. He was the discoverer of 23 asteroids, and of several comets, receiving the Lanlade medal from the Paris Academy in 1870 for the discovery of six asteroids in one year. In 1867 he was elected to the National Academy of Sciences, an institution to which he bequeathed \$16,000 for a research fund and the "Watson comet." He published 'Popular Treatise on Comets' (1860); 'Theoretical Astronomy' (1868); 'Tables for Calculation of Simple and Compound Interest and Discount' (1879), etc.

**WATSON, John**, Canadian philosopher: b. Glasgow, Scotland, 25 Feb. 1847. He was graduated from Glasgow University in 1872 and in the same year was called to the chair of mental and moral philosophy at Queen's University, Kingston, Ontario. He has published 'Kant and His English Critics' (1881); 'Schelling's Transcendental Idealism: a Critical Exposition' (1882); 'The Philosophy of Kant as Contained in Extracts from His Own Writings' (1888); 'Comte, Mill and Spencer, an Outline of Philosophy' (1895); 'Hedonistic Theories, from Aristippus to Spencer' (1895); 'Christianity and Idealism' (1896); 'An Outline of Philosophy with Notes Historical and Critical' (1898); 'Philosophy of Kant Explained' (1908); 'Interpretation of Religious Experience' (1913).

**WATSON, John** ("IAN MACLAREN"), English Presbyterian clergyman and author: b. Manningtree, Essex, 3 Nov. 1850; d. Mount Pleasant, Iowa, 6 May 1907. He was educated at Edinburgh University, New College (Edin-

burgh), and the University of Tübingen, was licensed to preach by the Free Church of Scotland in 1874 and appointed assistant minister of the Barclay Church, Edinburgh. In 1875 he was ordained minister of Logiealmond (Perthshire) Free Church, whence he went in 1877 to Free Saint Matthew's, Glasgow, and in 1880 to the Sefton Park Presbyterian Church of Liverpool. He was Lyman Beecher lecturer at Yale in 1896, and in 1900 Moderator of the Synod of the Presbyterian Church of England. Among his religious works are 'The Upper Room' (1895); 'The Mind of the Master' (1896); 'The Potter's Wheel' (1897); 'Companions of the Sorrowful Way' (1898); 'Doctrines of Grace' (1900); and 'The Life of the Master' (1901). He also published several works of fiction, beginning with 'Beside the Bonnie Brier Bush' (1894), a very successful collection of sketches of life and character in Highland and semi-Highland parishes, and including further 'The Days of Auld Lang Syne' (1895); 'Kate Carnegie' (1896); 'A Doctor of the Old School' (1897); 'Afterwards' (1898) and 'Rabbi Sanderson' (1898); 'Life of the Master' (1901); 'Inspiration of Our Faith' (1905); 'Children of the Resurrection' (1908).

**WATSON, John Broadus**, American psychologist: b. Greenville, S. C., 9 Jan. 1878. He was graduated at Furman University in 1900, and took his Ph.D. at the University of Chicago in 1903. He was assistant and instructor in psychology at Chicago in 1903-08; and from 1908 occupied the chair of experimental and comparative psychology at Johns Hopkins University and was also director of the psychological laboratory there. He was commissioned major in the aviation section of the Signal Corps of the United States Reserves in 1917. He was editor of the *Psychological Review* in 1908-15, and is joint editor of the *Journal of Animal Behavior*. Author of 'Animal Education' (1903); 'Behavior—An Introduction to Comparative Psychology' (1914); 'Homing and Related Activities of Birds' (1915); 'Suggestions of Modern Scientists Concerning Education' (1917), etc.

**WATSON, John Crittenden**, American naval officer: b. Frankfort, Ky., 24 Aug. 1842. He was graduated from the United States Naval Academy in 1860, was promoted master in 1861 and assigned to the *Sabine*. He was transferred to the *Hartford*, flagship of Admiral Farragut, in 1862 and served under him throughout the war. He participated in the battles of Fort Jackson and Saint Philip, served in the passage of the Vicksburg batteries in 1862, of Fort Hudson in 1863 and was engaged at Mobile Bay in 1864. He received rank as lieutenant-commander in 1866, as commander in 1874 and in 1877-80 was in command of the *Wyoming*. He was lighthouse inspector in 1880-86, promoted captain in 1887 and commodore in 1897. In the Spanish-American War of 1898 he commanded the blockading squadron on the northern coast of Cuba, was transferred to the command of the *Oregon* later in that year and in 1899 succeeded Admiral Dewey in charge of the Asiatic squadron at Manila, with rank of rear-admiral. In 1900-02 he was president of the naval examining board and since then has been president of the examining and retiring board. He retired in 1904.

**WATSON, John Fanning**, American antiquary: b. Batsto, N. J., 1780; d. Germantown, Pa., 23 Dec. 1860. He was a bookseller in Philadelphia for many years and made a careful study of early and Revolutionary history. His publications include 'Annals of Philadelphia' (1830); 'Historic Tales of the Olden Times in New York' (1832); 'Annals of New York City and State' (1846); 'History of the United States' (1856).

**WATSON, Musgrave Lewthwaite**, English sculptor: b. Hawkdale, Cumberland, near Carlisle, 1804; d. London, 28 Oct. 1847. Meeting Flaxman in London in 1823 he gained the friendship of that sculptor, through whose influence he was admitted to the schools of the Royal Academy. He subsequently visited Rome, working under Chantrey (q.v.) and Behnes. His productions include a terra cotta relief, 'Suffer Little Children to Come Unto Me'; and statues of Flaxman, Nelson, Chaucer and Queen Elizabeth.

**WATSON, Paul Barron**, American author: b. Morristown, N. J., 25 March 1861. He was graduated from Harvard in 1881, subsequently studied law and was admitted to the bar and has practised in Boston. His published writings are a 'Bibliography of the Pre-Columbian Discoveries of America,' privately printed in 1881, and included in the fourth (enlarged) edition of 'America Not Discovered by Columbus,' by R. B. Anderson (q.v.); 'Marcus Aurelius Antoninus' (1884), the first extended biography of the subject in English; and 'The Swedish Revolution under Gustavus Vasa' (1889).

**WATSON, Richard**, English Anglican prelate: b. Heversham, Westmoreland, August 1737; d. Calgarth Park, Westmoreland, 4 June 1816. He was graduated from Trinity College, Cambridge, in 1759, became professor of chemistry there in 1764 and in 1771 was appointed regius professor of divinity. He became archdeacon of Ely in 1780 and in 1782 was consecrated bishop of Llandaff. His writings include 'An Apology for Christianity' (1770); 'Chemical Essays' (5 vols., 1781-88); 'An Apology for the Bible' (1790), etc. Consult his son Richard, 'Anecdotes of the Life of Richard Watson' (1817).

**WATSON, Richard**, English Methodist clergyman: b. Barton-upon-Humber, Lincolnshire, 22 Feb. 1781; d. London, 8 Jan. 1833. He joined the Wesleyan Methodists at 15 and began preaching. He was ordained in 1800 and shortly afterward joined the Methodists of the New Connection, returning to the Wesleyans in 1812. He was appointed secretary of the Wesleyan Missionary Society in 1817 and in 1826 was president of the conference. He was for a time editor of the Liverpool *Courier* and wrote 'Apology for the People Called Methodists' (1800); 'Life of the Rev. John Wesley' (1831); 'A Biblical and Theological Dictionary' (1831); 'An Exposition of the Gospels of Matthew and Mark' (1833), etc. His collected works were edited by Thomas Jackson, in 13 vols., 1834-37, with 'Memoir.'

**WATSON, Robert Spence**, English publicist and lawyer: b. Gateshead, 8 June 1837; d. 1911. He was educated at University College, London, and established a law practice in Gateshead and Newcastle. He was president

of the National Liberal Federation in 1890-1902 and has taken an active part in educational movements in Newcastle. He is also known for his writings on economic subjects, particularly the labor question. His publications include 'Industrial Schools' (1867); 'Higher Education in Boroughs' (1868); 'The History of English Rule and Policy in South Africa' (1879); 'Irish Land Law Reform' (1881); 'The Relations of Labor to Higher Education' (1884); 'Boards of Conciliation and Arbitration and Sliding Scales' (1886); 'The Peaceable Settlement of Labor Disputes' (1889); 'Labor, Past, Present and Future' (1889); 'The Recent History of Industrial Progress' (1891); 'The Duties of Citizenship' (1895); 'Reform of the Land Laws' (1906), etc.

**WATSON, Sereno**, American botanist: b. East Windsor Hill, Conn., 1 Dec. 1826; d. Cambridge, Mass., 9 March 1892. He was graduated from Yale in 1847, studied medicine at the University of New York and in 1867-69 was botanist to the government exploration of the 40th parallel under Clarence King (q.v.). In 1871 he became assistant curator at the Gray Herbarium at Harvard and from 1874 until his death was curator there. He was elected Fellow of the National Academy of Sciences in 1889. Among his publications are 'Botany'; Vol. V of 'Reports on the Geological Exploration of the 40th Parallel' (1871); 'Bibliographical Index to North American Botany, Part I, Polypetalæ' (1878); with W. H. Brewster and Asa Gray, 'Botany of California' (2 vols., 1876-80), etc.

**WATSON, Thomas**, English poet: b. London, about 1557; d. 1592. While his fame may seem to have been eclipsed by that of Spenser and Sidney, among his contemporaries he was equally popular for his pastoral and love poetry. He lived in a learned age and translated the 'Antigone' of Sophocles into very elegant Latin. His 'Melibeus, Thomæ Watsoni; seu, Ecloga in Obitum Domini Francisci Walsinghami, Equitis Aurati' (1590) was a graceful Virgilian tribute to the memory of the statesman and diplomat Francis Walsingham (q.v.). His sonnets, 'Tears of Fancie; or Love Disdained,' evidently gave suggestions to Shakespeare in the composition of his 'Sonnets.' Consult Arber, 'English Reprints' (1892).

**WATSON, Thomas Edward**, American lawyer and politician: b. Columbia County, Ga., 5 Sept. 1856. He entered Mercer University but did not complete the course there and then took up the study of law and was admitted to the bar in 1875. He began the practice of his profession at Thompson, Ga., and rapidly attained a reputation as one of the leading lawyers of the State. In politics he was at first a Democrat; was elected to the State legislature in 1882 and served as Democratic elector-at-large in 1888. He was active in the Farmers' Alliance movement and finally affiliated himself with the People's Party; in 1890 he was elected to Congress on the Populist ticket and for some time edited a Populist paper at Atlanta. While in Congress he obtained the first appropriation for the rural free delivery of mail. He was the nominee of the People's Party for Vice-President in 1896 and for President in 1904 and in 1908 of the Populist Party. His publications include 'The Story of France' (1898); 'Life of Na-

oleon' (1902); 'Life and Times of Thomas Jefferson' (1903); 'Handbook of Politics and Economics' (1908); 'The Story of the South and West' (1911); 'The House of Hapsburg' (1915), etc.

**WATSON, William**, American scientist: b. Nantucket, Mass., 19 Jan. 1834. He was graduated from the Lawrence Scientific School of Harvard in 1857; was an instructor there in 1857-59; in 1859-63 was in Europe collecting information on technical education, which, when communicated to W. B. Rogers, was made the basis of the organization of the Massachusetts Institute of Technology; and from 1865 to 1873 was professor of mechanical engineering and descriptive geometry in that institution. In 1884 he was elected secretary of the American Academy of Arts and Sciences. In addition to numerous technical papers he has published various writings, including 'Technical Education' (1872); 'Course in Descriptive Geometry' (1873); 'Courses in Shades and Shadows' (1889); 'The Civil Engineering, Architecture and Public Works of the Paris Exposition of 1889' (1891); and 'The International Water Transportation Congress, Chicago, 1893' (1894).

**WATSON, SM William**, English poet: b. Burley-in-Wharfedale, Yorkshire, 2 Aug. 1859. He was privately educated and in 1880 published his first volume of verse, 'The Prince's Quest and Other Poems,' which showed the influence of Keats and William Morris and found favor with Rossetti. In 1884 he issued his 'Epigrams of Art, Life and Nature,' containing much highly-finished work, but it was not till the publication of 'Wordsworth's Grave and Other Poems' in 1890 that he gained adequate recognition. The volume of his 'Poems' published in 1892 was a reprint of the 1890 volume with the addition of 26 new pieces. Of 'Lachrymæ Musarum and Other Poems' (1892), the title-poem is a fine eulogy of Lord Tennyson. 'The Eloping Angels' followed in 1893, 'Odes and Other Poems' in 1894 and 'The Father of the Forest and Other Poems' in 1895. To 1896 belong two volumes of sonnets on the Armenian atrocities, with the titles 'The Year of Shame' and 'The Purple East'; to 1897, 'The Hope of the World and Other Poems.' His 'Collected Poems' (1898) ought rather to be called 'Selected Poems,' since from them are excluded all of the 1880 and 1893 volumes, more than half of the 'Epigrams,' most of 'The Year of Shame' and portions of the other volumes. He wrote in 1902 one of the more prominent odes on the coronation of Edward VII and in 1903 'For England.' He has written in prose a volume of literary essays, 'Excursions in Criticism' (1893). In 1909 he brought out 'New Poems,' in 1913 'The Muse in Exile,' in 1916 'Retregression and Other Poems,' in 1917 'The Man Who Saw.' Watson's work is carefully wrought, reflective in tone and marked by an air of distinction. It has been sometimes criticized as occasionally too closely an echo of greater poets. He was prominently mentioned among the possible successors to Tennyson and Alfred Austin in the laureateship but the honor went elsewhere. In 1917 he received the honor of knighthood.

**WATSONVILLE**, wõt'sòn-vil, Cal., city in Santa Cruz County, on the Pajaro River and

on the Southern Pacific Railroad, about five miles from Monterey Bay, an arm of the Pacific Ocean and 18 miles southeast of Santa Cruz. It is in an agricultural and fruit-growing region. Sugar beets are one of the chief products grown in the vicinity. The principal manufacturing establishment is the sugar beet factory; which has a beet-crushing capacity of over 1,000 tons and a sugar manufacturing capacity of over 200 tons each day. There are four banks and two daily newspapers. Pop. 6,000.

**WATT, wõt, James**, Scottish engineer: b. Greenock, Renfrewshire, 19 Jan. 1736; d. Heathfield, near Birmingham, Staffordshire, 25 Aug. 1819. Having determined to adopt the trade of mathematical instrument maker, he spent a year in London learning the art, in which he attained great dexterity and after his return endeavored to set himself up in business in Glasgow. In this he might not have succeeded owing to the opposition of other workers in the trade, had he not been appointed (1757) mathematical instrument maker to the university, which was outside of the jurisdiction of the Glasgow municipality. While thus employed he was also active in preparing surveys and reports in connection with canal, river and harbor work. It was during this period that he thought of and completed most of his improvements of the steam-engine. The idea of a separate condenser first occurred to him in 1764 and in January 1769 he took out the patent for the improvements of the steam-engine in which this idea was applied. Previous to Watt's time the cylinder itself had been used as a condenser and the jet of cold water introduced into the cylinder to condense the steam so reduced the temperature of the cylinder that three times as large a supply of steam (so Watt estimated) was demanded as was really needed. Watt set to work to condense the steam in a separate receptacle. The change was so important as to make him almost the inventor of the modern engine. But it was not until the year 1774 that he united with Matthew Boulton (q.v.), a manufacturer at Birmingham, in order to carry his improvements into execution. In consequence of this he removed to Soho, near Birmingham, where the establishment in which his steam-engines were manufactured soon acquired a European fame. He retired from the business in 1800, when his patent, which had been renewed in 1775 for 25 years, expired. Watt was a Fellow of the Royal Societies both of London and Edinburgh and one of the few natives of Great Britain who have been elected members of the National Institute of France. Besides the expedient of the condenser, Watt made also other improvements in the steam-engine. He devised the sun-and-planet gear-wheel, made use of the expansion principle to obtain the double engine, applied the governor to the regulation of the speed of steam-engines and invented the throttle-valve. He built the first indicator for drawing a diagram of steam pressure and also patented a fuel-saving furnace, invented copying ink and independently discovered the chemical composition of water. He had a retentive memory and the range of his reading was very wide. Chemistry, architecture, music, law, metaphysics and language were the principal subjects which, in addition to physical science and its practical applications,

engaged his attention and in all of them his knowledge was wonderfully extensive, minute and accurate. (For an account of the improvements that Watt effected in the steam-engine see STEAM; STEAM-ENGINE). The significance of his work places him among the foremost of inventors. Consult Muirhead, 'Origin and Progress of the Mechanical Inventions of James Watt' (1854); a 'Life' abridged from the preceding (1858); Smiles, 'Lives of Boulton and Watt' (1865); Thurston, 'The Growth of the Steam-Engine' (1879) and an article by Cowper in the 'Transactions' of the Institution of Mechanical Engineers for 1883.

**WATT**, in *electricity*, the unit of activity or rate of doing work, named after James Watt (q.v.). See ELECTRICAL TERMS, Vol. 10, p. 167; ELECTRICAL UNITS, Vol. 10, p. 168.

**WATT-HOUR**. See ELECTRICAL TERMS.

**WATTEAU**, vä-tô, Jean Antoine, French painter: b. Valenciennes, 10 Oct. 1684; d. Nogent-sur-Marne, 18 July 1721. His parents, whose situation in life was humble, with difficulty contrived to give him the instructions of a very inferior master in the country. In 1702 he went to Paris, in company with a scene-painter, with whom he continued to work for a few months. Soon afterward he found employment with one Claude Gillot, who, although only a painter of decorations for ballet and a designer of costumes and of patterns for tapestry, was a true artist. With him he found an opportunity of practising in all these branches of art and when he left him he found another master in Claude Audran, a very able man, keeper of the Luxembourg, who was of great service to him in opening to him the famous gallery of the palace in which Rubens had painted in allegory the history of Marie de Médicis. From the study of the great Flemish master he improved his coloring and when he left Audran in 1709 he was a consummate master of his art and a painter of "Fêtes Galantes." He now began to paint on his own account, but met at first with little encouragement. He failed to secure the "Prix de Rome," which would have enabled him to visit Italy, but soon afterward scored a triumph by his 'Un Départ de Troupes.' He was admitted to the Académie in 1717 as a painter of "Fêtes Galantes" and produced many pictures whose power and grace in drawing and coloring his rivals strove in vain to emulate. His subjects were all genre, military and civil. He excelled in reproducing the costumes, airs and graces of the fashionable world of his time. His 'L'occupation selon l'Age' sold in 1891 for \$27,300. The finest collection of Watteau paintings is in Berlin, others are to be seen in the Wallace collection, London, in the Louvre, Paris, and in the Petrograd, Vienna, Edinburgh and Glasgow galleries. Consult Goncourt, E., 'Catalogue raisonné de l'œuvre peint, dessiné et gravé d'Antoine Watteau' (Paris 1875); Pater, W., 'A Prince of Court Painters' (in 'Imaginary Portraits' London 1887); Foster, J. J., 'French Art from Watteau to Trud'hon' (London 1905); Mauclair, C., 'De Watteau à Whistler' (Paris 1905); Pilon, E., 'Watteau et son école' (Brussels 1912); Staley, E., 'Watteau and his school' (London 1902).

**WATTERSON**, wôt-ér-sôn, Henry, American journalist: b. Washington, D. C., 16 Feb. 1840. He was privately educated, and began journalistic work as editorial writer for the Washington *Star*. In 1861 he joined the Confederate army as a private, and later was aide-de-camp to Generals Forrest and Polk. In 1862 he withdrew from the army to edit the *Rebel* at Chattanooga, a daily paper, recognized as an organ of the Confederate government, but in 1864 returned to the army, and had part in General Johnston's campaign, and the siege of Atlanta. After the war he revived the publication of the Nashville *Republican Banner*; and in 1867 became editor of the Louisville *Journal*. This paper he united with the *Courier*, under the name of the *Courier-Journal*, of which he became editor-in-chief and which he has made one of the leading Southern newspapers. He has been active in politics as a member of the Democratic party, although a leader in the Liberal Republican program of 1872; was delegate-at-large to every Democratic National Convention from 1872-92, and was permanent chairman of that of 1876. He was a member of Congress in 1876-78, and hotly opposed all greenback ideas. Though a staunch supporter of Tilden for the Presidency, yet in Congress he was one of the leaders in obtaining a peaceable adjustment of the election dispute, and approved the appointment of the Electoral Commission, 1877 (q.v.). In 1896 he refused to support the Chicago platform of the Democratic party, and was affiliated with the Gold Democrats. As a defender of the tariff, he was not over strenuous, believing that its main purpose was to raise revenue. He was ever antagonistic to trust policies and the dominance of industry by great capital. As speaker and editor he has been a consistent advocate of free trade, and particularly of a policy of conciliation between the North and the South. He retained his vigor of utterance and influence in politics in his latter days. He has published 'Oddities of Southern Life and Character' (1882); 'History of the Spanish-American War' (1899); and 'Abraham Lincoln' (1899). In 1911 he was conspicuous as being among the first to urge the fitness of Woodrow Wilson for the Presidency. His famous slogan "To hell with the Hapsburgs and Hohenzollerns" in 1917 was largely instrumental in arousing the United States to war against the German atrocities and brutal disregard of the rights of neutral nations. On 2 March 1919 a world-wide tribute was paid him in the special 'Marse Henry edition' of the Louisville *Courier-Journal* in which over 200 thinkers and statesmen of the world voiced their esteem of the veteran editor.

**WATTLE-BIRD**, or **WATTLE-CROW**, an Australian honey eater (*Anthochaera carunculata*), so named from the large reddish wattles on its neck. It is about the size of a magpie, and is of bold, active habits.

**WATTLES**, arborescent shrubs (*Acacia*) of Australia and Tasmania, in some places growing to good-sized trees. They have foliage which is compound or reduced to phyllodia, and pretty, crowded flowers, in globose or cylindrical heads. The wattles furnish a gum, used as an adhesive in cotton-printing; the stems make poles, which are serviceable for many

‘bush’ purposes. The bark is a valuable tanning material, known as mimosa- or wattle-bark, and many of the acacia forests have been killed by the stripping of their cortex for this purpose. A good quality of tan-bark is obtained from *A. decurrens* and *A. mollissima*, the black, green or feathered wattle found also in South Africa. It is one of the most graceful of the acacias and least destructive of its thorny race to person and clothing. The silver wattle (*A. dealbata*) is a taller tree than the black wattle, with ashen-tinted young foliage. The African wattle is *A. natalitia*; the Alpine, *A. pravissima*, from the Victorian Alps. *A. juniperina*, the prickly wattle, is an evergreen shrub of Australasia. The raspberry-jam wattle (*A. acuminata*) of the same region, yields a cabinet wood, having the odor of that sweetmeat. The wallaby- (*A. rigens*) and varnish-wattle (*A. verniciflua*), are also Australian shrubs. The soap-pod wattle is the same as the soap-nut of India. Savannah wattles are West Indian trees (*Citharexylum quadrangulare* and *C. cinerea*) of the verbena family.

**WATTMETER.** See ELECTRICAL TERMS.

**WATTS, wōts, George Frederick**, English painter: b. London, 23 Feb. 1817; d. there, 1 July 1904. He studied in the Royal Academy and in 1837 exhibited there two portraits of young ladies and a subject-picture entitled ‘The Wounded Heron,’ and afterward contributed to various art exhibitions, notably the Royal Academy, the Grosvenor Gallery and the New Gallery, about 300 pictures of various kinds. Some of these are landscapes and seascapes; a few, such as ‘The Sempstress’ and ‘Under the Arch,’ portray contemporary life; but the finest and most characteristic are portraits and allegorical or ideal subjects. His portraits include those of the most eminent men and women of his age and perhaps form his chief claim to renown, as they were the basis of his reputation as an artist, and yet many of his idealistic pictures will continue to be copied after all the portraits are forgotten. Of his other pictures the following may be mentioned: ‘Isabella Finding Lorenzo Dead’ (1840); ‘Paolo and Francesca’ (1848); ‘Life’s Illusions’ (1849); ‘Sir Galahad’ (1862); ‘The Wife of Pygmalion’ (1868); ‘Daphne’ (1870); ‘The Curse of Cain’ (1872); ‘Dedicated to all the Churches’ (1875); ‘Love and Death’ (1877); ‘Time and Death’ (1878), like the preceding one of his most notable pictures; ‘Orpheus and Eurydice’ (1879); ‘Psyche’ (1880); ‘The Rider on the Pale Horse,’ ‘The Rider on the Black Horse,’ ‘The Rider on the White Horse’ and ‘The Rider on the Red Horse,’ all apocalyptic pictures of 1883; ‘Love and Life’ (1884); ‘Rain Passing Away’ (1884); ‘The Angel of Death’ (1888); ‘The Wife of Plutus’ (1889); ‘She Shall be Called Woman’ (1892), a large picture of Eve; ‘For He Had Great Possessions’ (1894); ‘The Outcast’ (1895); ‘Jonah’ (1895); ‘Love Triumphant’ (1898); ‘Court of Death’ (1902). He was in Italy during 1843-47, and was powerfully influenced by Titian and Tintoretto. In 1847 his colossal oil-pictures of ‘Echo’ and ‘Alfred inciting the Saxons to prevent the Landing of the Danes’ were awarded a prize of £500 in another Westminster Hall competition. The latter of these now

adorns a committee room of the Houses of Parliament. He completed a fresco, ‘Saint George Overcomes the Dragon,’ in 1853, for the Houses of Parliament and at a later date painted in fresco the west end of the new hall at Lincoln’s Inn. After 1896 he was on the list of retired academicians. A large number of his portraits, presented by him to the nation, are now in the National Portrait Gallery, and some of his best allegorical paintings were presented to the National Gallery of British Art (Tate Gallery). To use his own words, he painted ideas rather than objects and the poetic idealism to which he was faithful throughout all his long career stood in the way of extensive popularity. His drawing was of the utmost correctness and his coloring often extremely fine, but while his allegorical subjects were often great in conception and treatment they sometimes required too much literary exposition to appeal to the ordinary picture lover in a clear and direct manner. His ‘Life’ has been written by his wife, Mary S. Watts, and appeared in London in 1912 in three volumes. Consult also Monkhouse, ‘British Contemporary Artists’ (1889); Bateman, ‘G. F. Watts’ (1901); Chesterton, ‘G. F. Watts’ (1904); Chesterton, G. K., ‘G. F. Watts’ (New York 1909).

**WATTS, Isaac**, English Congregational divine: b. Southampton, 17 July 1674; d. Stoke, Newington, London, 25 Nov. 1748. He was educated for the ministry at an academy in Stoke-Newington. In 1696-1702 he was a private tutor, in 1699-1702 was assistant to Isaac Chauncy, minister of the Congregational chapel in Mark Lane, London, and in 1702 succeeded to the pastorate. The congregation here was a distinguished one. Watts remained nominally pastor until his death, though from 1713 ill-health frequently interrupted his ministry, and Samuel Price was made co-pastor. Watts had in his own time great popularity as a writer, his manuals of religious instruction and his works of popular divinity having large circulation; while his ‘Horæ Lyricæ’ (1706) admitted him to Johnson’s ‘Lives of the Poets’ and was reprinted in 1834 in a series of ‘Sacred Classics’ with a memoir by Southey, and his hymns, numbering in all about 600, were the chief part of the psalmody of English Nonconformist congregations. At the beginning of the 18th century only a few unimportant hymns had been written for Dissenters’ use, the rule of Calvin having permitted only canticles and metrical Psalms. The dearth of suitable tunes and the custom of ‘lining out’ hampered Watts’ work; he had, too, many defects in rhyme and diction, was at times rhetorical and at others prosaic. But a number of his hymns are among the finest and most popular in English. Many are found in all hymn-books, and about a dozen remain in very general use. A collection was made in 1707, a second edition appearing in 1709. He published in 1722-24 doctrinal treatises of an Arian tendency, but grounds are wanting for believing that he finally passed to that position. His ‘Works’ were edited by Jennings and Doddridge in 1753; the ‘Posthumous Works’ were published in 1779. The former were reprinted with additions, and a memoir by Burder, in 1810. Consult Gibbons, ‘Memoirs’ (1780); Milner, ‘Life’ (1834);

Hood, 'Life' (1875); Julian, 'Dictionary of Hymnology' (1892).

**WATTS, Mary Stanbery** (Mrs. MILES TAYLOR WATTS), American author: b. Delaware County, Ohio, 4 Nov. 1868. She was educated at the Convent of the Sacred Heart, Cincinnati, and early engaged in literary work. She is well known as a writer of short magazine fiction and of novels dealing with American life. Author of 'The Tenants' (1908); 'Nathan Burke' (1910); 'The Legacy' (1911); 'Van Cleve' (1913); 'The Rise of Jennie Cushing' (1915); 'The Rudder' (1916); 'The Boardman Family' (1918), etc.

**WATTS, Thomas Hill**, American politician: b. Butler County, Ala., 3 Jan. 1819; d. Montgomery, Ala., 16 Sept. 1892. He was graduated from the University of Virginia in 1840, established a law practice in Greenville, Ala., was elected to the State legislature in 1842, 1844-45, and to the State senate in 1853. He opposed the secession movement, but upon the secession of Alabama accepted the situation. He was appointed colonel in the Confederate army and fought at Shilo, but resigned shortly afterward to become attorney-general in the Confederate Cabinet. He was elected governor of Alabama in 1863, but was unseated by the Federal government at the close of the war. He was thereafter engaged in law practice at Montgomery, and with the exception of 1880-81, when he served in the legislature, held no further public office.

**WATT'S DYKE.** See OFFA'S DYKE.

**WATTS-DUNTON, Theodore**, English poet, critic and novelist: b. Saint Ives, Huntingdonshire, 12 Oct. 1832; d. 17 June 1914. He was educated privately at Cambridge and for a time studied law, but had already gained a reputation as a writer of sonnets when he joined the staff of the *Examiner* as literary and art critic. Later he joined the *Athenaeum* staff, and for many years was one of the chief contributors to that review, his criticisms of poetry being of the most illuminating character. In 1897 he published a poem entitled 'Jubilee Greeting at Spithead to the Men of Greater Britain,' which met with wide appreciation; and in the same year collected in 'The Coming of Love, and Other Poems,' some of the more important of his poetical contributions. 'Aylwin,' a novel or romance published in 1898 (privately printed in 1883), forms a striking prose counterpart to the 'Coming of Love,' and contains excellent pictures of gypsy life. Watts-Dunton has also contributed largely to the *Nineteenth Century* and other periodicals. Several of the notices in Ward's 'English Poets' are from his pen, and the valuable critical article on poetry in the *Encyclopaedia Britannica* was written by him. He and Swinburne (q.v.) were intimate friends. Later publications are 'The Christmas Dream' (1901), and 'The Renaissance of Wonder' (1902). On occasion Watts-Dunton makes free use of the Romany dialect, which he has carefully studied. His best work is probably the critical, especially that dealing with the principles of verse. Consult Miles, 'Poets and Poetry of the Century,' (Vol. IV, 1901); also

an article in the *Idler* (Vol. V), and Nicoll in the *Contemporary* (Vol. LXX

**WAUGH, wa, Arthur**, English author: b. Midsomer Norton, Somerset, 24 Aug. 1859. He was graduated from Oxford in 1880, was a journalist in London in 1890, was London correspondent of the *New York Critic* in 1891, and in 1894 was sub-editor of the *London Review*. He acted as literary adviser to Paul and Company in 1895-1902, and in 1903 was managing director of the London publishing firm of Chapman and Hall. He has 'Gordon in Africa' (1888); 'Alfred Tennyson, a Study' (1892); 'Legends of the Wheel' (1898), etc.; and has edited 'The Lives of the Poets' (6 vols., 1896); *Biographical edition of Dickens* (19 vols., 1902-03); and other works.

**WAUGH, Frederick Judd**, American painter: b. Bordentown, N. J., 13 Sept. 1861. He attended the Pennsylvania Academy, Philadelphia, and lived and worked abroad in Paris, and exhibited at the Paris Salon in 1907. He exhibited at the Paris Salon of the Royal Academy, London, and also as a newspaper illustrator in London. He lived at Montclair, N. J., after his return from Europe, and gained a considerable reputation as a painter of marines. His work is well represented in both public and private collections. He was elected to the National Academy of Design in 1911. Among his works are 'The Roaring Forties' (The Metropolitan Museum of Art, New York); 'Surf and Fog, Monhegan Island, Maine' (The Art Institute, Chicago); 'After a North Wind' (National Gallery, Washington); 'The Gulf Stream' (Pennsylvania Academy, Philadelphia), etc.

**WAUKEGAN, wa-ké'gan**, Ill., city, and seat of Lake County, on Lake Michigan, and on the Chicago and Northwestern, the Rock Island, Joliet and Eastern (Belt Line) and the Chicago and North Western, 30 miles north of Chicago and 50 miles west of Milwaukee. There are two electric lines which connect the city with the lake port of Chicago and with the nearby villages and towns. The city is situated on a bluff about 80 feet above the lake. The fine beach and a good harbor, which has been improved, thus giving Waukegan the status of a lake port. It is in an agricultural region, but the city is best known for its manufacturing industries. The chief industrial establishments are steel and wire works, which employ about 2,500 employees; sugar refineries; brass and iron works, a tannery, a wood-working factory, wrapper factory, and material works, electric scale works and a stop factory. The city ships large amounts of lumber, coal, salt, iron, grain and manufactured products. The principal public buildings are the county courthouse, the municipal building, the Jane McAlister Hospital, the library, the churches and the schools. There are a number of churches, a high school, public and parochial schools, and the Carnegie public library. A United States naval training station is close by. There are three banks and several daily newspapers. The government is situated on the commission plan. The city was settled in 1835 by Thomas Jenkins, who was incorporated in 1849, and chartered as a city in 1859. Pop. 19,571.

high school established in 1871, grammar and primary schools, an opera house and a town hall. Pop. 5,119.

**WAVERLY**, Ohio, village, county-seat of Pike County, on the Scioto River, and on the Norfolk and Western, and Ohio Southern railroads, 57 miles south of Columbus. It is in an agricultural and stock-raising region, and contains flour and saw mills, tanneries, distilleries and furniture factories. There is a high school with a school library of over 1,000 volumes; two banks and two newspapers. Pop. 2,100.

**WAVES OF ASSAULT.** In modern warfare the intense effort demanded of assaulting troops, and the successive attacks which they must make, necessitate a deep formation. The several echelons thus constituted have been given the name of *waves*. But this term does not signify a uniform formation. The foremost waves, generally the first and the second, advance in line; those following are in various formations, for example, in lines of small columns. Moreover, to facilitate the leading of the echelons, the waves are formed by the simultaneous advance of tactical units not deployed in single line but themselves extended in the direction of depth, from which it results that a company or battalion will form a part of several successive waves. Formation for the assault does not consist of the deployment of rigid lines capable only of a movement straight to the front, but, on the contrary, of placing side by side tactical units which are capable of being led and even manoeuvred.

The waves are crowded into the first-line trench and the parallels in the immediate rear, sometimes in double rank. They dash forward, following each other at short distances so as to rapidly cross the zone of hostile barrage fire. Theoretically an assaulting battalion leaves a single block of its parallels of departure and then while marching takes the distances prescribed between waves. In no event should these waves close up automatically on the leading wave, as its only effect would be in thickening the skirmish line, increasing the losses, and mixing the units. To avoid such effects, when the first wave has crossed the advanced hostile trench it continues its advance toward the objective assigned to it. The other waves follow in good order. They engage successively according to the necessities of the situation under orders from the commanders of the several units. The assault is now followed by a combat in the interior of the position. At certain points the enemy yields, at others he resists stubbornly. The assailants, rallying about the officers that remain, rush into the opening and surround the nuclei of resistance. As soon as the trench is carried the attack pauses only long enough to reform, and the groups of assailants then dash into every opening that offers. Their audacity constitutes their strength. These scattered combats bring the assailants in contact with a new line of defense. If it is occupied, they dig themselves in, in order to form a line of departure for an assault by the reinforcements.

EDWARD S. FARROW,  
Consulting Military and Civil Engineer.

**WAVES AND WAVE-MOTION.** Wave is the name commonly given to a disturbance of the surface of a body in the form of a ridge

and trough, propagated by forces tending to restore the surface to its figure of equilibrium, the particles not advancing with the wave. A more complete and scientific definition of a wave is that particular form of aggregation assumed by the molecules between the nearest two consecutive surfaces in which similar phases simultaneously exist throughout. The theory of wave-motion is of the utmost importance in all physical science, and the general investigation of the form and rate of propagation of waves demands the application of the highest resources of mathematics. The theory of even such comparatively simple cases as the wind-waves in deep water (the Atlantic roll, for instance) though easily enough treated to a first, and even to a second and third approximation, has not been thoroughly worked out, as fluid friction has not been fully taken into account. To find the rate at which an undulation runs along a stretched cord, as for instance, when a harp-string is sharply struck or plucked near one end, a very simple investigation suffices. Suppose a uniform cord to be stretched with a given tension in a smooth tube of any form whatever, we may easily show that there is a velocity with which the cord must be drawn through the tube in order to *cease to press on it at any point*, that is, to move independently of the tube altogether. For the pressure on the tube is due to the tension of the cord; and is relieved by the centrifugal force when the cord is in motion. If  $T$  be the tension of the cord,  $r$  the radius of curvature of the tube at any point, the pressure on the tube per unit of length is  $\frac{T}{r}$ . If  $m$  be the mass of unit

length of the cord,  $v$  its velocity, the centrifugal force is  $\frac{M v^2}{r}$ . These are equal in magnitude,

and so destroy each other, if  $T = mv^2$ . Hence, if the cord be pulled through the tube with the velocity thus determined, these will be no more pressure on the tube, and *it may therefore be dispensed with*. If we suppose the tube to have a form such as that in Fig. 1, where the extreme

FIG. 1.

portions are in one straight line, the cord will appear to be drawn with velocity  $v$ , along this, the curved part being occupied by each portion of the cord in succession; presenting something like the appearance of a row of sheep in Indian file, jumping over a hedge. To a spectator moving in the direction of the arrow with velocity  $v$ , the straight parts of the cord will appear to be at rest, while an undulation of any definite form and size whatever runs along it with velocity  $v$ , in the opposite direction. This is a very singular case, and illustrates in a very clear manner the possibility of the propagation of a *solitary wave*. Thus we prove that the velocity with which an undulation runs along such a cord is the square root of  $T$  divided by  $m$ .

If  $l$  be the length of the cord in feet,  $w$  its whole weight,  $W$  the appended weight by which it is stretched,  $g = 32.2$  feet, the measure of the earth's gravity, this becomes  $\left(\frac{W}{w}lg\right)$ . This

formula is found to agree almost exactly with the results of experiment. We can easily see why it should be to some small extent incorrect, because we have supposed the cord to be inextensible and perfectly flexible, which it cannot be; and we have neglected the effects of extraneous forces, such as gravity, the resistance of the air, etc.

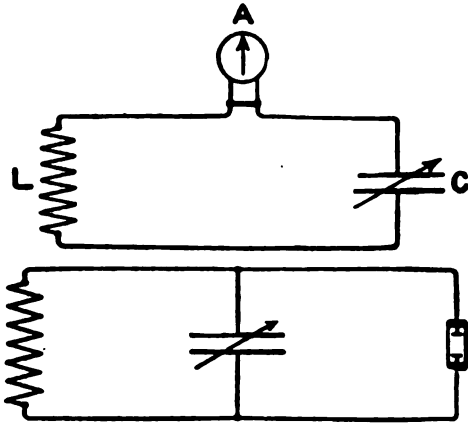

FIG. 2.—Ammeter in Circuit to Indicate Resonances.

In geometrical investigations it has been proved that the velocity with which a sound wave travels is proportional to  $\left(\frac{p}{d}\right)^{\frac{1}{2}}$  where  $p$  is the pressure, and  $d$  the density of the air. The easiest mode of doing this is to express, in terms of these and other quantities, the equation given by the laws of motion, Mass  $\times$  Acceleration = Difference of Pressures, and to assume that Hooke's law holds, even during the sudden compression of air. The foregoing formula shows that the velocity of sound is not affected by the pressure of the air (the height of the barometer) since, in still air,  $p$  is proportional to  $d$ . The velocity does depend on the temperature, being, in fact, proportional to the square root of the temperature measured from absolute zero. We also see from the formula that the velocity is inversely as the square root of the density of the gas—the pressure being the same. Thus a sound wave travels about four times faster in hydrogen than in air. Also, within the limits of approximation we have used, the velocity does not depend upon the intensity, pitch, or quality of the sound.

**WAVEY**, the common name in the Hudson Bay region for the smaller wild geese, especially the snow-geese. See **GEESE**.

**WAX**, fatty solid animal substance, of which the typical sort is called beeswax. Various similar substances of vegetable and animal origin bear the name. Beeswax is secreted by bees in constructing their hives, and a very similar

vegetable product enters into the composition of the pollen of flowers, covering the plum and of other fruits, especially the berry of the *Myrica cerifera*, and in many instances forming a kind of varnish to the face of leaves. It is distinguished from fatty resinous bodies by its not readily forming a solid mass when treated with alkaline solutions. Beeswax is always more or less colored, and has a distinct, peculiar odor, of both of which may be deprived by exposure in thin layers to air, light and moisture, or more speedily by the action of chlorine. At ordinary temperature wax is solid and somewhat brittle; but it may be easily cut with a knife, and the fresh surface presents a characteristic appearance, to which the name of waxy lustre is applied. Its specific gravity is 0.96. At 155° F. it enters into fusion, and boils at a high temperature. Heat to redness in a closed vessel it suffers decomposition, yielding products very similar to those which are procured under the same circumstances from oil. It is insoluble in water and is only dissolved in small quantities by alcohol or ether.

In bleaching wax the wax must be melted with a degree of heat not sufficient to alter its quality, in a caldron so disposed that the wax may flow gradually through a pipe at the bottom of the caldron into a large wooden cylinder that turns continually round its axis upon which the melted wax falls. As the wax falls upon this cylinder it does not solidify but quickly becomes solid and flat, and assumes the form of ribbons. The continual rotation of the cylinder carries off these ribbons as they are formed, and distributes them to the tub. When all the wax ribbons are whitened is thus formed, it is to be put into large frames covered with linen cloth, and are supported about a foot and a half above the ground in a situation exposed to the dew and the sun. If the weather be favorable, the color will be nearly discharged in a few days. It is then to be re-melted and formed into ribbons and exposed to the action of air as before. These operations are to be repeated till the wax is rendered perfectly white when it is cast into cakes or other convenient form.

The principal applications of wax are to make candles and medicinal cerates; to polish to furniture or floors, for which purpose it is largely used in the United States to form a lute or cement, for which it is used by chemists; and to serve as a vehicle for colors. By modern painters colors previously dissolved in oil are sometimes diluted just before being laid on in a mixture of wax and oil of turpentine. This practice is much resorted to by French artists, especially in mural painting. The object is to keep the painting free from that lustrous appearance which often renders it difficult to be seen properly in consequence of reflection. Wax also forms a principal ingredient in modelers' wax and gilders' wax. In the former the other ingredients are artists' lead-plaster, olive oil, yellow resin, whiting; and in the latter verdigris and a plate of copper. Sealing-wax is not pure wax at all, but is composed of resin and some less brittle resin. The largest con-

tion of wax takes place in Roman Catholic countries, where large quantities are required for the candles used in religious ceremonies.

Chinese wax comes from the ash-tree where it is secreted by an insect. It resembles spermacetic. Cork wax or cerin is extracted from cork by an alcoholic process. Mineral wax or ozocerite is a waxy paraffine sometimes found in coal measures. Shoemakers' wax is a mixture of pitch and tallow. Wool wax is the solid greasy product obtained from sheep washing, is used as a dressing for leather, and is an adulterant or base for ointments. See also WAX, VEGETABLE.

**Wax Figures.**—The employment of wax in imitative art dates from a period anterior to historical times, although, according to Pliny, the art of casting it in molds was not practised previous to the time of Lysistratus, its reputed inventor, who flourished about 300 B.C., and whose productions were chiefly portraits cast in plaster molds taken from the face. Wax portraits eventually became common, and among the Romans, who placed them in the vestibules of their houses, were regarded as an evidence of ancient nobility, as none were allowed to possess such images whose families had not borne some curule magistracy. In the Middle Ages, wax was employed in the construction of images of saints and of votive images, and those who practised sorcery melted before a slow fire wax figures of the persons against whom their incantations were directed. In the latter half of the 15th century Andrea del Verrocchio and Orsino gained considerable reputation by some figures of Lorenzo de' Medici, their joint production, which consisted of frameworks of wood or skeletons for the bodies and limbs, while the heads, hands and feet were cast in wax, painted in oil colors to counterfeit life. They were furnished with glass eyes and natural hair, and were habited in the costume usually worn by Lorenzo. The manufacture of wax figures of the size of life is still carried on to a considerable extent, but has long ceased to be considered a branch of the fine arts, no imitative skill or taste on the part of the artist being sufficient to overcome the ghastly fixedness which such images must always present, and which is the more disagreeable as the resemblance to life is closer. In the preparation of anatomical models and pathological examples, however, wax has been very advantageously employed, the invention being due to Gaetano Giulio Zumbo, a famous modeler in colored wax, who flourished in the latter half of the 17th century. In the succeeding century the celebrated collection of anatomical models in the Institute of Bologna was begun under the direction of Ercole Lelli, the finest specimens being by Giovanni Manzoli and his wife, Anna Morandi Manzoli. In the Museum of Natural History at Florence are 15 chambers devoted to preparations by Fontana, Susini and other celebrated modelers; the Musée Dupuytren at Paris is famous for its morbid specimens; and almost every considerable city of Europe now has its collection.

The collection of wax figures at the Eden Musée in New York was for about 50 years prior to 1910 one of the show features of the city.

**WAX, Mineral.** See HATCHETTITE.

**WAX, Vegetable,** a solid, fatty substance, resembling animal wax, which is secreted by many plants, sometimes in large enough quantities to be of commercial importance. It forms, on foliage, a varnish or coating, which prevents excessive transpiration or wetting of the cells; and, on twigs and flower-pedicels, by its slippery surface keeps unwelcome insects from reaching the flowers and robbing them of their honey. The whitened under surfaces of some willow leaves and the bloom of fruit are composed of wax either in granules or rods or spread over the cuticle. The most familiar example in America of the hard fat or wax in quantity is on the bony nutlets of the wax-myrtles or bayberries (*Myrica*). The gray-coated drupes of *M. carolinensis* clustering on the bare twigs are conspicuous in seashore regions, after the leaves are fallen; the wax clinging to their rough, granular surfaces when melted is a greenish, hard substance, sharing the balsamic odor of the plant. It was used in colonial times as a basis for candles and for scap. Other species, of other countries, furnish a similar wax and are known as candle-berries or tallow-trees. Carnauba wax is exported from Brazil for candles and as a substitute for beeswax. It is the coating on the young leaves of *Corypha cerifera*, indigenous to tropical South America. The young leaves are removed and dried. The wax-granules may then be shaken off, in the form of a fine dust, melted and caked. A varnish-like exudation of wax, on the stems of two other South American palms, *Klopstockia cerifera* and *Ceroxylon andicola*, the wax-palm, the latter being a tall tree, slightly thickened at the centre of the trunk and crowned by a tuft of pinnate leaves. This wax is scraped off and melted. A mixture of resin and wax results, from which the latter is extracted by hot alcohol, and is then utilizable for candles. It is, however, seldom seen in commerce. Japan wax is a wax-like, hard fat, which is largely exported from Japan to Europe, in yellowish hard cakes, with a resinous, rancid odor, and often covered with a powdery efflorescence. It is mixed with or substituted for beeswax, where its rancid odor is not preventive and is extracted by several methods, such as heating under pressure or boiling from the crushed drupes of an oriental species of sumac (q.v.).

**WAX-BILL, or SENEGAL FINCH,** an African weaver-bird (*Estrilda astrilda*), one of the section of the family called blood-finches on account of the prevalence of red in the plumage. This has long been a favorite among cage-birds and is sold by dealers all over the world. It is nearly five inches long. The beak is bright red and somewhat swollen. A bright red stripe passes between the eyes and the middle of the breast and belly is a beautiful reddish-brown. The upper surface of the body is brownish-gray, the lower surfaces lighter, everywhere traversed by very fine blackish wavy lines; wings and tail brown. They are varied much in color by breeders, bright blue tints, even, having been developed in some. Their song is not very musical, but they are pretty and affectionate to a high degree. Their food and care should be similar to those given to a canary.

**WAX-FLOWER, or MADAGASCAR JASMINE.** See STEPHANOTIS.

**WAX INSECT.** See SCALE INSECTS.

**WAX-WING**, a woodland bird of the family *Ampelidae*, a small isolated group of birds of the northern hemisphere, characterized by their shrike-like beaks, silky brown plumage, tall erectile crests and especially by the tips of the wing and tail-quills terminating in flattened scales closely resembling red sealing-wax. There are but three species, the northern or Bohemian wax-wing (*A. garrulus*); the Siberian wax-wing (*A. phanicoptera*), and the common North American cedar-bird (q.v.). The northern wax-wings make their home near the Arctic coasts of both continents and breed there, in trees, long before the snow has disappeared in spring. Sometimes they are not seen in the United States or Central Europe for years together; then will appear in large numbers locally. These erratic movements are doubtless due to presence or absence of food, which consists of both insects and berries (the latter mainly, of course, in winter), but were regarded by the superstitious peasantry of Europe as signs of some visitation of war or pestilence to follow. All the wax-wings are cinnamon-brown, relieved by handsome markings of black, gray and yellow.

**WAXAHACHIE**, wäks-ä-häch'é, Tex., town, county-seat of Ellis County, on the Missouri, Kansas and Texas and the Houston and Texas Central railroads, about 178 miles northeast of Austin, the State capital, and 31 miles south of Dallas. It was founded in 1847. It is in an agricultural and stock-raising region, in which are produced large crops of wheat and a good quality of cotton. The manufactories are cottonseed-oil mills, cotton compresses and flour mills. It is a cotton centre for an extensive region. The principal public buildings are the county courthouse (original cost \$150,000), Trinity University, three banks, six churches, schools and a library. There are besides a daily, weekly and monthly (college) newspapers. Pop. 8,000.

**WAXWORKS**, the representation in wax of figures, ornaments or other articles, but in popular usage confined to that of figures of real persons. For the history and development of modeling in wax see article on *Wax Figures* under WAX. In modern public exhibitions of waxworks only the heads and hands of the figures are modeled in wax, the figures being clothed as in life; and in some cases a mechanism is added to make them capable of movement. The figures reproduced are usually those of notable personages of different periods. There is also usually a department in which startling happenings are represented, as in the "Chamber of Horrors" at the Eden Musée, New York, where notorious criminals were shown in wax. The Eden Musée was long a famous showplace of New York, but waning public interest resulted in its closing its doors in 1915. Other noted exhibits of the sort are those of Madame Tussaud (q.v.), in London, and the figures of the sovereigns of England formerly in the Tower of London.

**WAXY** or **AMYLOID DEGENERATION.** See DEGENERATION; PATHOLOGY.

**WAY, Arthur S.**, English classical scholar; b. Dorking, 13 Feb. 1847. He was Fellow of Queen's College, Melbourne, Australia; was

classical lecturer in Queen's College, Ta in 1870-76 and was the head of the W College of Melbourne in 1882-92. In 1877, came examiner in Latin to the Central board of secondary education. His public include English verse-renderings of 'Odyssey' (1880) and 'Iliad' (i-xii, xiii-xxiv, 1889); of the tragedies of Eur (1894-98); of Horace's 'Epodes' (1898) of Apollonius Rhodius' 'Tale of the nauts'; he has also published 'Letters of Paul to Seven Churches and Three F (1901); 'David the Captain' (1904); ' to the Hebrews' (1906); 'Orestia' (I 'The Cyclops of Euripides' (1912); 'V Georgics in English Verse' (1912); 'V Æneid in English Verse' (I-III, 1916).

**WAY, Right of.** See REALTY.

**WAY OF ALL FLESH, The**, the titl novel by Samuel Butler (q.v.) put posthumously in 1903. It is the history of generations of the author's family and brilliant satire on the church, family rel ships and the education of children. N are hundreds of facts in the author's life minutely recorded; it is a spiritual biography as well. Bernard Shaw in the ace to Major Barbara, says that he li more from Butler than anyone else i perfection of paradoxical style and the of reversing moral dynamics.

**WAY OF THE WORLD, The.** W Congreve was already the leading play and one of the most elegant gentl London when in 1700 in his 30th ye brought out at Lincoln's Inn Fields 'The of the World' with his friend Mrs. B in the principle rôle of Millamant. The y written with a conscious aspiration "t only to the few refined." It was at a purpose "to design some characters should appear ridiculous, not so much a natural folly (which is incorrigil therefore not proper to the stage) as th an affected wit, a wit which at the sam that it is affected is also false." The v was not entirely a success and C career as a playwright was at an end.

It may profit us to inquire why th failed and why in spite of its failure hailed as one of the greatest of the comedies. By the time of Congreve the been added to the over-emphasis and tesqueness of Jonson's comedy the r touch of Molière. Comedy now beco art of manners, a pattern of human at its wittiest and best. It was C distinction that he best adapted the te of town living to the technique of Interested in character he is even more ested in social groups:

"poets oft in one piece expose whole bellies—assemblies of coquettes and bus

The play is rendered caviare to the g by its super-abundance of dazzle, a ra that conceals, as by principle, the real of some at least of the characters. Mo the characters quite run away with the in their good spirits and lavish life. his plot unclear and a matter of rav i and hasty explanations. But these th not be counted faults by one wh

Congreve. He only among English writers has raised the artifices of character to universality. In language, observation, wit he presents a fine texture of grace that provokes and satisfies thoughtful laughter. Millamant is one of the rarest creations in literature, the woman entrancing as distinguished from the woman emotional or the woman instinctive. Though he is dealing with a conventionalized society Congreve's characters are thoroughly individualized in their several relationships with that society. As is natural for such a society, most of the characters are women, but the characters that stand out, with one exception, are men. Written after Jeremy Collier's blast against the immorality of the stage, the play shows some of the restraining influence of this divine's charges. It was often presented during the 18th century, but has been the particular delight of the study. Editions: Ewald, A. C., ed., *Mermaid Series*, 1887; Street, G. S., *Comedies of William Congreve*, 1895; Archer, W., *Masterpieces of English Drama*, 1912. Consult Gosse, E., 'Life of Congreve' (1888); Meredith, G., 'An Essay on Comedy' (1879); Lamb, C., 'On the Artificial Comedy of the Last Century'; Thackeray, W. M., 'English Humorists'.

THOMAS H. DICKINSON.

**WAYCROSS**, Ga., city and county-seat of Ware County, 98 miles southwest of Savannah, on the Atlantic Coast Line and the Atlantic, Birmingham and Atlantic railroads. There are deposits of brick clay and of building sand in the vicinity. Industries include railroad construction and repair shops and the manufacture of cigars, naval stores, machinery, gasoline engines, turpentine and other products. Pop. 19,001.

**WAYCROSS**, wā'krōs, Ga., city, county-seat of Ware County, on the Waycross and Western, the Atlanta, Birmingham and Atlantic, the Waycross and Southern and the Atlantic Coast Line railroads, about 95 miles southwest of Savannah. Large meat-packing interests are located here and the government maintains naval stores. There are saw and planing mills, car repair shops, a cotton gin and turpentine plant. There are two banks and four newspapers, one of daily issue. The educational institutions are a high school (white), established in 1890, a high school (colored) and public and private schools. Pop. 18,500.

**WAYLAND**, wā'land, Francis, American college president: b. New York, 11 March 1796; d. Providence, R. I., 30 Sept. 1865. He was graduated from Union College in 1813, studied in the Andover Theological Seminary, was a tutor at Union College 1817-21; in 1821 became pastor of the First Baptist Church of Boston and took a leading place in the ranks of American preachers, his sermon on 'The Moral Dignity of the Missionary Enterprise' (1823) being particularly well known. After holding a professorship at Union (1826-27), he became president of Brown University. During the 28 years of his administration he greatly developed the institution and was one of the pioneers of the elective system in American universities. Subsequent to his resignation (1855) he was for a year and a half

pastor of the First Baptist Church of Providence, after which he devoted himself to various kinds of religious and humanitarian effort. He was the author of many valuable works, including 'Elements of Moral Science' (1835); 'Elements of Political Economy' (1837); 'Limitations of Human Responsibility' (1838); 'Domestic Slavery Considered as a Scriptural Institution' (1845); 'Elements of Intellectual Philosophy' (1854); and 'Sermons to the Churches' (1858). Consult Murray, S. O., 'Francis Wayland' (Boston 1891); Wayland, F. and H. L., (his sons), 'Life and Labors of Francis Wayland' (New York 1867).

**WAYLAND**, Francis, American legal scholar, son of the preceding: b. Boston, 23 Aug. 1826; d. New Haven, Conn., 9 Jan. 1904. He was graduated from Brown University in 1846, took his M.A. degree from Yale in 1872, and began law practice in Worcester, Mass., in 1850, removing in 1858 to New Haven. He was judge of probate in 1864-65, and lieutenant-governor of Connecticut in 1869. In 1872 he became professor in the law school of Yale, and in 1873 dean of the school. In 1903 he resigned the deanship. The development of the school from a minor local institution to its present condition, with adequate financial basis and wide curriculum, is due chiefly to him. He was president of several organizations, including the American Social Science Association, the board of directors of the Connecticut State Prison, the Prison Aid Association from 1872, and the Organized Charities Association of New Haven from 1878. He was prominent as a writer and speaker on sociological and charitable topics and criminology, and was joint author, with his brother, H. L. Wayland, of the 'Memoir' of President Wayland (1867).

**WAYLAND THE SMITH** (Ger. *Wieland*, vē' lānt; Norse, *Völundr*; A. S. *Wēland*), a hero of old Teutonic saga. His myth assumes numerous forms. It appears in Scandinavian, Anglo-Saxon and German poems. The name probably signifies the "skilful" or "artful" one. Wayland seems to be a deification of the smith, whose calling was considered among the highest. Episodes in the story narrate that Wayland was, like Vulcan, lame, and, like Dædalus, manufactured wings and could fly. These are thought, however, to have been late introductions from the classic mythology. In France, too, Galans the Smith was known. Simrock employed the various legends in his epic 'Wieland der Schmied' (1835). The megalithic monument in Berkshire called "Wayland Smith's cave," with the character Wayland, empiric farrier, and pedlar, is familiar through Scott's 'Kenilworth.' Consult Maurus, 'Die Wielandsage in der Litteratur' (1902).

**WAYNE**, wān, Anthony, American soldier: b. Easton, Pa., 1 Jan. 1745; d. Presque Isle (Erie), Pa., 15 Dec. 1796. At 18 he became a land-surveyor. He was an intimate friend of Franklin, and early took an active interest in public affairs. Having married and settled to farming (1767), he was elected to the Pennsylvania convention and legislature in 1774, served on the committee of safety, and in 1775 raised a regiment, with which he took part in the campaign against Canada. He fought with

distinction and was wounded at the battle of Three Rivers 3 Jan. 1776, held Ticonderoga till May 1777 and after receiving the commission of brigadier-general joined Washington in New Jersey; led a division at Brandywine 11 September and commanded the right wing and led the attack at Germantown 4 October. He made a dashing raid on the British lines in the winter of 1777-78, carrying off a great quantity of supplies, and on the night of 15 July 1779 achieved the most brilliant of the American victories in the storming of Stony Point, for which he received a gold medal and the thanks of Congress. He became a popular hero, and his nickname of "Mad Anthony" was as much a tribute to his energy and valor as it was a denotation of his recklessness in action. By a bayonet charge he rescued Lafayette in Virginia in 1782; made a daring attack on the whole British army at Green Spring (6 July), and defeated the British and Indians in Georgia. On the surrender of Charleston, S. C., by the British it was occupied by Wayne, 14 Dec. 1782. He was made brevet major-general 10 Oct. 1783, retired from the army in 1784 and became a member of the Pennsylvania legislature. He was a member of the convention of that State which ratified the Federal Constitution in 1787. Later he settled on a Georgia plantation presented to him by the State in return for his military services; and from Georgia, in 1791, he was sent to Congress, but in a contest during the next year his seat was declared vacant. In April 1792, he was made commander-in-chief of the American army, with the rank of major-general. In 1793 he took the field against the Indians in Ohio, whom he finally defeated at Maumee Rapids or Fallen Timbers and he forced them to conclude the treaty of Greenville (1795), which gave a large tract of territory to the United States. His death occurred while he was engaged in completing this service. A monument was erected to him at Waynesboro, Pa., 1809. Consult the 'Lives' by Armstrong (1834) and Moore (1845); Wayne's 'Regimental Orderly Book' on the northern campaign, edited by J. Munsell (1859); Stillé, 'Wayne and the Pennsylvania Line' (1893); Roosevelt, 'Winning of the West,' Vol. IV (1889-94); and Spears, 'Anthony Wayne' (1903).

**WAYNE, James Moore.** American jurist: b. Savannah, Ga., 1790; d. Washington, D. C., 5 July 1867. He was graduated at Princeton University in 1808, was admitted to the bar in 1810, and engaged in practice at Savannah. He served for two years in the Georgia legislature, was mayor of Savannah in 1823, and was judge of the Superior Court in 1824-29. He was a member of Congress in 1829-35; and was appointed by President Jackson an associate justice of the Supreme Court of the United States 9 Jan. 1835. He was a recognized authority on admiralty jurisprudence. He opposed the re-chartering of the United States Bank.

**WAYNE, Neb.,** city, county-seat of Wayne County, on the Chicago, Saint Paul, Minneapolis and Omaha Railroad, about 95 miles north by west of Lincoln and 85 miles northwest of Omaha. It is in an agricultural region, in

which the principal productions are wheat, corn, sugarbeets and potatoes. Wayne makes extensive shipments of grain, hogs, cattle, hay and vegetables. It has the Nebraska Normal College (private), a high school and public graded schools. There are four banks and two newspapers. Pop. about 2,140.

**WAYNESBORO, wānz'hūr-ō, Ga.,** city, county-seat of Burke County, on the Central Railroad of Georgia, about 100 miles northwest of Savannah and 30 miles south of Augusta. It was laid out as a town in 1783, and in 1888 was incorporated as a city. The chief manufactures are cottonseed-oil mills, a wagon factory, agricultural implement works, a meat-packing plant and a cotton compress. It has seven churches, one public high school or academy, and Waynesboro Academy (a private high school), elementary public schools, two banks and a newspaper. A battle was fought here during the Revolutionary War, and one during the Civil War. Pop. about 2,729.

**WAYNESBORO, Pa.,** borough in Franklin County, on the Mont Alto and West Maryland railroads, about 48 miles southwest of Harrisburg. It is the commercial and industrial centre of quite an extent of territory. The chief manufacturing establishments are four large machine factories, employing a total of 2,500 men, also foundries, tool works, creameries, ice-machine and engine works, and a plow factory. There are four banks, two daily and two weekly newspapers. The borough is near South Mountain and Antietam Creek. The Confederate army passed through Waynesboro on the way to and from Gettysburg. Pop. about 9,720.

**WAYNESBORO (Va.), Battle of.** On 27 Feb. 1865 General Sheridan started from Winchester, Va., on his final campaign up the Shenandoah Valley, under instructions from General Grant to destroy the Virginia Central Railroad, the James River canal, capture Lynchburg, if practicable and join General Sherman, wherever he might be found in North Carolina, or return to Winchester. He had Custer's and Devin's divisions of cavalry and two sections of artillery, about 10,000 officers and men, the whole commanded by General Merritt, his chief of cavalry. At Mount Crawford, 1 March, he was met by Rosser's cavalry which was promptly dispersed, and 2 March he reached Staunton, which had been abandoned by General Early, who had fallen back eastward to a ridge west of and near Waynesboro, where he could muster only Wharton's two small brigades of infantry, Nelson's battery of six guns and Rosser's cavalry, in all not over 1,800 men. Merritt followed from Staunton, and late in the afternoon, after some artillery-firing, three of Custer's dismounted regiments moved around Early's left flank, between it and South River, while two of his brigades charged his front. Early's men made but a feeble resistance and broke in a disorderly rout, hotly pursued by the Union cavalry through Waynesboro and as far as the South Fork of the Shenandoah and to Greenwood Station, where five guns were captured and several loaded cars burned. Merritt took as prisoners 1,450 officers and men and captured 11 guns with horses and caissons complete, 200 loaded

wagons and several battle-flags. Generals Early, Long, Wharton, Lilley and Rosser, with a few men, escaped. From Waynesboro the prisoners and captured artillery were sent back to Winchester, under guard of 1,600 men. Early's army had disappeared and Sheridan moved unmolested to the Virginia Central Railroad, which was destroyed for several miles. The swollen conditions of the rivers made it impossible to join Sherman and Sheridan determined to destroy still more thoroughly the railroad and James River canal and then join Grant in front of Petersburg. He divided his command, sending one part to the James River canal, which it destroyed as effectually as the other part destroyed the railroad. This done, he moved to White House on the Pamunkey River, where he arrived on 19 March 1865, and thence to the army in front of Petersburg. Consult 'Official Records,' (Vol. XLVI); Pond, 'The Shenandoah Valley in 1864'; Sheridan, 'Personal Memoirs' (Vol. II); Early, 'Last Year of the War for Independence'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN,

**WAYNESBURG**, wānz'berg, Pa., borough, county-seat of Greene County, on Ten Mile Creek and on the Waynesburg and Washington Railroad, about 44 miles south of Pittsburgh. It is in an agricultural and stock-raising region, and in the natural-gas and oil belt. It has flour mills, a foundry, a planing mill, a carriage factory, a machine shop and creameries. It is the seat of Waynesburg College (Cumberland Presbyterian). There are five banks and two newspapers. Pop. about 3,545.

**WAYNESBURG COLLEGE**, located at Waynesburg, Pa. It was chartered in 1850 and first opened to students in 1851. It was established by and is under the control of the Pennsylvania Synod of the Cumberland Presbyterian Church, and the trustees are elected by this synod. In 1902 the board of trustees was increased from 11 to 21 members, and the Alumni Association empowered to submit 12 nominations, from which six trustees shall be elected. The college for many years labored under serious financial difficulties, and it was not until 1898 that an adequate endowment was obtained, which was increased in 1900. Since that time the curriculum has been extended, especially in the study of sciences, and the equipment greatly improved. The college offers three regular courses, classical, literary and scientific, which lead to the degrees of A.B., B.L. and B.S. Greek is required for the A.B. degree. These courses all include some electives in the work of the last two years, the list of electives from which the student may choose differing in each course. The degree of A.M. is conferred for graduate work; courses leading to the Ph.D. degree have been discontinued. In addition, the college maintains a preparatory department, a normal department, a conservatory of music, and a school of oratory. The college adopted the system of co-education at the first, and has found it most successful. The students maintain two literary societies and a Young Men's and a Young Women's Christian Association. The buildings include the main building and Hanna hall, a dormitory. There are well-

equipped chemical and biological and physical laboratories, recently established. The library in 1918 contained 10,000 volumes, and the productive funds amounted to \$90,000. The students numbered 270 and the faculty 23.

#### WAYS AND MEANS COMMITTEE.

See UNITED STATES — FINANCES; SENATE, UNITED STATES.

**WAZAN**, or **WEZZAN**, wā-zān', Morocco, an inland town, picturesquely situated on the steep northern slope of a two-peaked mountain, in the hill country 90 miles southeast of Tangier. It is a sacred city of refuge, and a place of pilgrimage, the headquarters of the grand sheriff, the spiritual ruler of Morocco. The principal buildings are the great mosque and the tombs of a long line of sheriffs. The trade is, as elsewhere in Morocco, mainly in the hands of the Jews. Pop. about 16,000. Consult Watson, 'A Visit to Wazan' (1880).

**WAZIRISTAN**, wā-zē-rī-stān' the country of the Waziris, Northwestern India, a mountainous region situated west of the Suliman range, north of British Baluchistan, and east of Afghanistan. It is now partly included in British India, and has at various times been the scene of military operations owing to the depredations and raids of the Waziris on the caravans traversing the Gomul Pass. The British government maintains political agencies in both Northern and Southern Waziristan. The principal town is Kanigoram. It is a mountainous country, with much fine scenery, and a delightful climate except in some of the valleys. The Waziris, a portion of whom are known as Mahsuds, are a hardy race of Afghans. Some of them have settled peaceably within British territory, where they cultivate the land. Their crops are wheat, maize and barley; they raise horses and sheep, and iron and wood are exported.

**WEA** (contraction of *Wayatonuki*, "Eddy people"), a tribe of the Algonquin stock of North American Indians, belonging to the Miami confederacy. When first known to the whites, in 1672-1703, they were in Wisconsin, but they seem to have gradually drifted southward, and in 1701 one of their villages was on the site of the present Chicago, Ill., and in 1719 their chief village was on the Wabash below the mouth of Wea Creek, in Indiana. They were hostile against the whites in western Virginia, in which their country was situated, but they finally signed the celebrated treaty of Greenville in 1795, and in 1820 sold their last lands in Indiana and moved with the Piankashaws to Illinois and Missouri. In 1832 they again sold their lands and the main body moved to Kansas, whither a few of their number had already migrated. In 1854 the rapidly decreasing Weas and Piankashaws united with the Peorias and Kaskaskias of the Illinois confederacy; at this time, their population aggregated 259, largely mixed-bloods. In 1868 they moved to the Neosho Indian Territory, now Oklahoma, where the small remnant has been absorbed.

**WEAKFISH**, or **SQUETEAGUE**, a spiny-rayed fish of the genus *Cynoscion* and family *Sciaenidae*. It has no teeth on the vomer or palate bones, but numerous ones in the jaws, which are weakly in structure; the air-bladder

has a horn on each side projecting forward. The genus is chiefly American, with about 15 North American species. The common weakfish (*C. regalis*) is one to two and one-half feet long, brownish blue above, with irregular brownish spots, and tinged with greenish and banded in the young; the sides silvery, abdomen white, and iris yellow; lower fins orange; a single row of very small teeth in the upper jaw and a double series in the lower; dorsals separated, and the second, with the caudal and anal, mostly covered with scales. This is one of the most abundant fishes along the entire Atlantic Coast from Cape Cod to Florida, but there have been times when the invasions of bluefish have driven them from parts of the coast. The name originated from the little resistance it makes when taken, and from the ease with which the delicate structure of the mouth enables it to break away. This is the name most employed on the New Jersey Coast, while in New England the Indian name "squeteague" is usual, and in the South sea-trout is applied to this and to the spotted *Cynoscion*. On the New Jersey Coast it appears early in the spring, being most abundant toward the end of July, and disappears late in the autumn; it is a greedy biter, and is easily taken by any soft white bait, affording great sport for about an hour on the flood tide; it swims in shoals near the surface and requires a line slightly if at all leaded. In summer it is abundant about the mouths of rivers, where the water is brackish, and sometimes ascends far up, having been taken in the Hudson 50 miles above New York; it is taken by seines and poundnets in large quantities; when caught it makes a croaking sound, also heard when the fish is at the bottom. The flesh is wholesome and well flavored, but so quickly gets soft that it does not rank high in the market. The air-bladder makes excellent isinglass for culinary purposes. The spotted weakfish (*C. nebulosus*) is conspicuously marked with round black spots above and the soft-dorsal fin is not scaly. It is more southern than the squeteague, and is sometimes called spotted trout. Other related species occur in West Indian waters and on the Pacific Coast.

**WEALDEN**, wēl'dēn, certain delta-deposits of the Cretaceous (or Chalk system, from their great development in the weald of Sussex, England. Weald means in Old English a wood or forest, and the name is applied to a tract of country lying between the north and south downs of Kent and Sussex. The recognized geological name of this subdivision of the Cretaceous system is the Neocomian, from the old Latin name of Neuchâtel in Switzerland. This stage in the south of England, and thence eastward across Hanover, consists of a mass of sand and clay, sometimes 1,800 feet thick, representing the delta of a river. Only a portion of this delta remains, but as it extends in an eastern and western direction for a distance of at least 200, and from north to south less than 100 miles, its total area may have been 20,000 square miles, indicating a very large river flowing from a continent. The stream not improbably descended from the north or northwest. It carried down the drifted vegetation of the land, with occasional carcasses of the iguanodons and other terrestrial or amphibious creatures of the time. Beyond the area overspread by the

sand and mud of the delta, the ordinary sediments accumulated, with their common organic remains. From Yorkshire, they stretch eastward through north Germany, and are found at the base of the taceous system through France into Spain. See GEOLOGY.

**WEALTH.** Wealth may be defined as a state of being or as a category of A state of wealth is practically identical state of well-being. It is a condition which men possess most of the thing need. It is the opposite of a state of poverty. Wealth, however, is generally conceived as a category of goods. As a category of goods includes all those material things which have value or, which means the same thing, all material things of which the community possesses less than it would like to have. Or it consists of all those material things which the community thinks it worth while to store up in larger quantities than it already has.

From this point of view it will be seen there is a very close connection between wealth as a category of goods and wealth as a state of being, though there is an apparent paradox. Wealth is contrasted with free goods,—such as air, sunlight, beautiful scenery, abundant and so forth. It is obvious that the more goods the community possesses, the greater is its well-being. If an object which is now considered as wealth could be made sufficiently abundant to satisfy all possible needs, the community would undoubtedly be better off, but the object would have ceased to be wealth. It would be one less article to include in the category of wealth.

This paradox, however, is only an apparent one. The object of wealth which, in the above illustration, has become a free good, becomes such by reason of its abundance. Well-being is clearly improved by increasing abundance. Now any material thing is of which you can say that by increasing abundance you would increase the well-being of the community. After it has become sufficiently abundant, you can no longer say that. If we have enough air, you cannot say that we would be better off if we had more. It is when we have not enough that we can say that. Well-being, therefore, depends upon wealth in a very direct, immediate and practical way. Anything of which we need more than we have is wealth. Anything of which you have more,—more of it, more well-being, less of which you have,—is wealth. Anything of which you can say that it is worth our while to try to get more of it, is wealth; whereas anything of which you cannot say that, either because it is useless in itself or because we have as much as we can possibly use, is not wealth.

Wealth as thus defined becomes an important factor in the greatest and most practical of the problems of man on earth: namely, the problem of adaptation. In some respects there is a perfect adaptation between man and his environment. In such cases there is no particular reason why he should think about or care for his mind or body over the situation. In many other cases, however, in which he cannot find himself perfectly adapted. If the climate is too cold, he needs fuel, clothing and shelter. There is the best possible reach

he should exercise his mind and body over questions of this kind. If he lives in a climate where food is not spontaneously produced by nature he will find a scarcity of food. There is, therefore, the best possible reason why he should exercise his mind and body over the food question. So with respect to everything of which there is a scarcity or of which he feels the need of more than he has, he will work at his great problem of adaptation in proportion as he gives effective attention to these things and ignores those phases of the situation which are not susceptible of improvement. From this point of view one might almost say that wealth consists of those material things which it is worth our while to concern ourselves about.

Some difference of opinion has arisen as to whether the term wealth should include only material things. Are not intelligence and skill wealth? They are undoubtedly absolutely essential to the production of wealth, but it is not customary to call them wealth. It seems on the whole better to restrict the use of the term to those material things which are the objects of the exercise of the intelligence and skill rather than to include intelligence and skill themselves. If we begin to enlarge the definition of wealth, it would be very difficult to know where to stop. Should we include the physical texture of the human muscles and the chemical and biological processes which go on inside the human body in our category of wealth? These undoubtedly have a great deal to do with the production of wealth and with our general well-being, just as do air and sun-light, but these are not generally the objects of human endeavor and certainly are not consciously thought of in what we call the pursuit of wealth. All definitions are of course more or less arbitrary. It seems that we must draw the line somewhere between the things which are wealth, and the things which are not wealth. It seems better to include under wealth only those things of which it is worth our while to try to increase our supply.

T. N. CARVER.

**WEALTH OF NATIONS.** Writers on economics distinguish capital from wealth by including in capital only those commodities which are susceptible to reproduction or are employed as agents in reproduction, as land, timber, fisheries, rivers, roads, canals, ships, carriages, money, telegraphs, etc. The distinction might be useful if it were generally adopted; for a vast amount of capital is sunk in objects which are apparently non-productive, as temples, monuments, statues, pictures, musical instruments, and generally all artistic products. But as a matter of fact the distinction is not generally adopted, so that its utility is far from being convincing. No tax assessors, census canvassers nor lenders of money have adopted it. For this reason national capital and national wealth will, in the present article, be treated as synonymous.

Before the opening of the 17th century, a date which corresponds with the colonization of America, but few attempts were made to estimate the wealth of a nation, the rate of its growth, its relation to population, to the current rate of interest or to the local and variable character of the measure (money) which was

necessarily employed to compute it. The practical importance of these relations were left to the researches of a later age. Yet at the very opening of the century arose a genius who, suspecting the significance of these relations, laid the foundations for every economical work which in treating these subjects has commanded the respect of science. This was Giovanni (John) Botero, a Jesuit, and the author of 'Ragione di Stato,' or 'The Wealth of Nations,' of which an English translation by Robert Paterson appeared in 1606. Botero was followed by Mariana in Spain, Sully in France and Sir Charles D'Avenant in England, to the last of whom we are indebted for the earliest computations concerning the wealth of England, France and Holland; all of which computations relate proleptically to the quarter of a century preceding the accession of Charles I in 1625.

**England—Great Britain—United Kingdom.**—At a later period Sir Charles D'Avenant estimated the population, value of real estate and current "specie" of England, whether in the treasury or in circulation, for the year 1600, as follows: For the real estate, £72,000,000; specie, £4,000,000; conservative figures. From these data a comprehensive estimate has been compiled, as follows: Year 1600, population, 5,000,000; wealth, real and personal, £200,000,000; money (coins and exchequer tallies), £5,000,000. Upon the scattered but useful data of Sir Charles, strengthened by the almost contemporaneous estimates of Sir William Petty and others, Gregory King compiled the first contemporaneous estimate of the wealth of England in 1688, which he fixed at about £600,000,000, equal to about 3,000,000,000 Spanish dollars of that period; population, 7,700,000. From that time onward the progress of wealth in the United Kingdom has been computed as follows:

YEAR	Authority	Population, millions	Wealth, million dollars
1700	Gregory King (1712).....	8.0	3,500
1800	Sir W. Pulteney.....	16.0	8,753
1850	McKean and Bider.....	27.3	22,564
1875	Sir R. Giffen.....	32.0	42,740
1900	Based on Giffen.....	42.0	70,000
1903	Sir R. Giffen.....	42.4	72,998
1915	Based on Giffen.....	47.0	100,000

NOTE.—Government property and unproductive lands were not included in the estimates of wealth until 1875. In addition to his computation of wealth for the United Kingdom in 1903, Sir R. Giffen estimated the wealth of the British Colonies and Dependencies as follows: Canada, \$6,750,000,000; Australasia, \$5,500,000,000; India, \$15,000,000,000; South Africa, \$3,000,000,000; and the rest of the Empire, \$6,000,000,000; total for Colonies and Dependencies, \$36,250,000,000. Because this addition to British cadastres was a novelty, and because a large part of this wealth was represented by Indian and Colonial securities held in the United Kingdom and already included in its cadastres, it has not been included in the above table.

Out of 50 known cadastres relating to the wealth of the British isles, those above have been selected on account of their dates as illustrating the progress of wealth in equal periods of time and because they are practically from the same source: a political economist and statistician of the British Board of Trade. The advance during the century, from 1700 to

1800, appears to have been about two and one-half times; from 1800 to 1850 two and one-half times in 50 years; from 1850 to 1875 nearly twice in 25 years; and from 1875 to 1900 only 14 per cent in 25 years. The remarkable decrease in the progress of wealth and therefore of profits marked by the declining rate of interest on investments which prevailed from 1875 to 1900 has been attributed by British economists to the loss of profits in trade occasioned by German rivalry, especially in the woollens and iron and steel trades.

**France.**—Turning from Great Britain to France, although scattered data may be gleaned from the memoirs of Sully, Colbert, Turgot and Necker, no comprehensive cadastre of the wealth of France appears to have been made before Arthur Young and the other economists of the Revolutionary period; from which time to the present there exist some twenty-odd computations. From these have been selected the following ones, as illustrative of the progress of wealth in about equal divisions of time:

YEAR	Authority	Population, millions	Wealth, million dollars
1789	Arthur Young and others . . .	25.0	7,600
1815	Moniteur Industriel . . . . .	29.5	14,200
1840	Deduced from income and other data . . . . .	33.0	22,900
1865	Deduced from M. Vacher (1878) . . . . .	36.0	38,800
1890	Deduced from M. DeFoville (1888) . . . . .	37.0	53,600
1915	Deduced from Leroy Beaulieu and De Lavergne . . . . .	41.0	64,300

**NOTE.**—De Foville's cadastre includes securities. De Beaulieu's cadastre (of 1908) includes certain lands, roads, canals and personal property, for the first time. These have been deducted, to render it uniform with previous computations. Mr. James E. Dunning (*North American Review*, 1911) computed the annual savings of France at \$400,000,000; a substantial agreement with the growth of wealth shown in the table.

The progress of national wealth in France exhibits a rise, from 1789 to 1815, of about 50 per cent; 1815-40, about 60 per cent; and 1840-65, about 50 per cent; 1865-90 (period of the Franco-Prussian War), a fall to about 37 per cent; and 1890-1914, a fall to 20 per cent; for which there has appeared no adequate explanation except a decrease in the profits of trade.

**Germany.**—The German republic as now constituted was formed on the ruins of the empire of 1871 at the close of the Great War of 1914-18, hence the cadastral data relating to previous periods is more or less proleptical and inharmonious, not only as to computations of wealth, but even as to population. After a careful comparison of numerous conflicting authorities, the following statistics have been adopted as apparently the most authentic. The data since 1870 are based on official returns.

German national wealth appears to have increased during the decade 1850-60 to the extent of 15 per cent; 1860-70, 10 per cent; 1870-80, 18 per cent; 1880-90, 10 per cent; and during the four years following, 7 per cent. Afterward, in the five years ending 1914 the increase rose to 31 per cent. The figures are very instructive, and taken in connection with those relating to Great Britain and France, they

throw no little light upon the great events through which the world is now passing.

YEAR	Authority	Population, millions	Wealth, million dollars
1850	International Review, 1875 . . . . .	33.5	30,000
1860	Monthly Consular Reports, 1868 . . . . .	37.5	34,500
1870	Daily Consular Reports, April 29, 1911 . . . . .	43.0	38,000
1880	Deduced from same . . . . .	45.2	45,000
1890	Deduced from data of Prof. Ballod . . . . .	49.4	49,500
1894	Deduced from Dr. J. Riemser . . . . .	52.0	53,000
1909	Sir Francis Oppenheimer . . . . .	63.0	63,500
1911	Dr. Karl Helfferich . . . . .	65.0	72,500
1914	Deduced from official data . . . . .	70.0	83,300

**NOTE.**—Sir Francis reported to the British government a German computation of national wealth showing a gain of 58 per cent in 15 years. This percentage was attained by adding "personal property" to the extent of \$40,000,000,000; an inadmissible proportion. It has been reduced in the table to the usual proportion of personal to real property. Dr. Helfferich's computation relates to 1910-11 and estimates the German national wealth from "69 to 76" billion dollars. The table gives the mean of these two sums.

**The United States.**—This is the one country in which contemporaneous computations have been made at regular intervals concerning the progress of national wealth. As such they afford a means of measuring that progress with some degree of exactitude and of observing its correspondence with the profits derived from the discovery and utilization of natural resources, agriculture, cattle-raising, fisheries, mining, manufactures, shipping, the extension and profits of trade and the rate of interest which capital commands for its employment in these industries. Computations of the national wealth began with Adam Seybert in 1791 and extend at intervals of 10 years down to the present time. Until 1850 they were made by various unconnected authorities, most of them, however, by officers of the government, and one at least by formal order and under the supervision of the Treasury. In 1850 and decennially since that date they have been made officially by the Census Bureau; while taken together they are all deserving of the highest credit.

#### WEALTH OF THE UNITED STATES.

YEAR	Authority	Population, millions	Wealth, million dollars
1791	Adam Seybert, 'Statistics' . . . . .	4.0	730
1800	Pitkins' 'Statistics' . . . . .	5.3	1,072
1810	Pitkins' 'Statistics' . . . . .	7.1	1,588
1820	Pitkins' 'Statistics' . . . . .	9.4	1,822
1830	Pitkins' 'Statistics' . . . . .	12.8	2,653
1840	Tucker's 'Statistics' . . . . .	17.1	3,764
1850	United States Census . . . . .	23.2	7,136
1855	Report Secretary Treasury, 1856 . . . . .	27.0	11,353
1860	United States Census . . . . .	31.5	16,688
1870	United States Census . . . . .	38.6	30,088
1880	United States Census . . . . .	50.2	43,642
1890	United States Census . . . . .	63.1	65,037
1900	United States Census . . . . .	77.3	80,517
1904	United States Census . . . . .	83.8	107,106
1912	United States Census . . . . .	96.9	187,739

**NOTE.**—The later censuses include the populations of Porto Rico, Alaska and Hawaii, but not the Philippines. The censuses from 1880 and onward include from four to 12 billions of property exempt from taxation. The census of 1912 includes the cost of the United States navy ships and valuation of the privately owned water supply systems not embraced in previous computations; together about \$700,000,000.

he computations which have been  
wealth of nations are based upon  
Taxes being usually levied upon  
resources, such computations,  
ates of economists or returns of  
ls, embrace not the entire wealth,  
: more effective capital or repre-  
: of nations. Its rate of growth  
time, therefore, affords inductions  
portant and valuable character;  
elation of money to capital, the  
ses of taxation, the safe limits of  
ncial significance of an impartial  
: of justice and the probable fu-  
: of interest on permanent in-

of Wealth to Population.—Al-  
ble is in effect the balance sheet  
one that covers over a century of  
quest, industry and savings, it does  
ce disclose the progress of indi-

Because, for example, it shows  
the wealth per capita was \$200  
1,938, it does not follow that the  
h has increased nine or 10 times.  
f 1800 and the dollar of 1912,  
may have contained substantially  
ntity of metal, were of widely  
basing power; so different that it  
doubted whether the average per

capita wealth of to-day is much greater than  
it was a century ago. Not only has the number  
of dollars in circulation been enormously in-  
creased, their efficiency (velocity) in effecting  
exchanges has been enhanced by means of the  
check system, the transportation system and  
the post office.

In the year 1800, dollars, in order to effect  
distant exchanges, had to be transported by  
mounted messengers, mail-coaches or sailing  
vessels; now they are transmitted by railways,  
steamboats and telegraphs; formerly, even as  
to nearby exchanges, they were sent by hand;  
now they are paid by checks. For the most  
part only purchases over the counter are now  
settled with money. Another and opposite con-  
sideration must also be held in view. Formerly  
every family was obliged to keep a stock of  
provisions, raiment, arms and implements; and  
the valuation of these commodities helped to  
swell the returns of wealth made to the as-  
sessors. Such is now the superior organization  
of industry and trade that similar precautions  
are no longer necessary. The official returns  
now include little beyond real properties, their  
improvements and the stocks of producers,  
manufacturers and merchants; in short, taxable  
commodities. Any comparison of per capita  
wealth in dollars at one time with another  
which omits these considerations must, there-  
fore, be fallacious.

But while the average individual wealth in  
tangible things may not have greatly increased,  
another sort of wealth has taken its place,  
which, though it cannot be computed in money,  
has enormously multiplied the national wealth  
and diffused it among individuals. This is the  
wealth of education, knowledge and skill.

**Relation of Capital to Profit.**—The earlier  
cadastres of the United States embrace con-  
tinual accessions of territory, either by con-  
quest from the Indians or purchase from  
France and Spain. For this and other reasons  
the summations of wealth do not afford a re-  
liable guide to the average annual rate of profit  
in trade or investment. The doubling of na-  
tional wealth from 1820 to 1840 is equal to  
about 3½ per cent compounded annually. The  
doubling from 1850 to 1860 is influenced by the  
accession of California and other territory in  
consequence of the war with Mexico; while that  
from 1860 to 1870 is complicated by the Civil  
War and an inflated currency. From 1870 to  
1890 the returns indicate a profit on capital of  
about 4 per cent compounded annually; from  
1880 to 1900 about 3½ per cent; and from 1890  
to 1910 again about 3½ per cent, compounded  
annually. Even before the frequent repetition  
of 3½ per cent annual net profit at all normal  
periods, its identity with the net rate of in-  
terest for capital was gleaned from an analysis  
of the market rate of interest made in 1864. It  
is now widely recognized by economists, and  
as such it confers an additional value on the  
census returns and affords a useful guide to  
merchants, bankers and investors.

**Relation of Capital to the Rate of Interest.**  
—Temporarily and in any given market the  
rate of interest depends upon the local supply  
of money and credit; but in the long run and  
throughout any extensive country it depends  
upon the profits of production in agriculture,  
fisheries, mining, manufactures and the means  
of transportation; while these again depend

upon the rate at which the animals and plants increase and the minerals are produced under the hand of man. Other things being equal, were this rate to double, the net rate of interest (that is, the rate, divested of risk, taxes and the cost of superintending loans of capital) would tend to double; and contrariwise, were the rate of growth of the means of subsistence to diminish one-half, the rate of interest would tend to diminish one-half; for that would be all that capital could earn when invested in production. ('The Science of Money,' Chap. XIII).

Such being the case, it follows that the rate at which in the long run the capital of a nation increases (leaving out of view adventitious gains by discovery, invention or conquest, or, on the other hand, losses by war or other national calamity) affords a reliable indication of the prevailing rate of interest. Indeed, when stripped of all adventitious circumstances, the two things are seen to be essentially the same thing; the net rate of interest is itself the measure of national growth and vice-versa, the rate of national growth marks the net rate of interest.

**International Comparison.**—When the growth of capital in the United States is compared with that in other leading countries, the practical results of a liberal constitution, a common school system and the popular diffusion of education will be readily recognized. At the beginning of the 19th century Great Britain had a capital of \$8,753,000,000; in the course of a century it increased eight times. France had a capital of about \$11,000,000,000; in 100 years it increased about five times. According to an estimate from the data in Zimmermann's 'Survey' (London 1787), Germany, as now constituted, had a capital of about \$10,000,000,000; in 100 years it increased about four and one-half times. The United States had a capital of about \$1,000,000,000; and in the course of a century it has increased 88 times.

#### POPULATION AND CAPITAL IN THE YEAR 1800.

COUNTRY	Population	Wealth	Wealth, per capita
Great Britain.	16,000,000	\$8,753,000,000	\$547
France . . . . .	27,000,000	11,000,000,000	409
Germany . . . . .	20,000,000	10,000,000,000	500
United States..	5,300,000	1,072,000,000	202

Before the events which, preceding the European War of 1914, began to disturb the normal rate of progress in each country, Great Britain annually added to her national capital about 2½ per cent; France, 2⅙ per cent; and Germany less than 2 per cent. Meanwhile the United States was increasing (is still increasing) her national wealth to the extent of about 3½ per cent per annum. Were it regarded as a fair reward of superior industry, skill and invention, this rapid rate of progress in wealth would stand in no jeopardy of arrest. But in the fierce rivalry of international interests the palm of victory has not only to be won; it has to be defended.

National wealth cannot be deduced solely from either population, income, taxation, wages, the prices of commodities or the stock of money. In attempting to do this, many of the computations cited in Mulhall's 'Statistics,'

Putnam's edition of Hayden's 'Dictionary of Dates' and other works of reference, have ended in the wildest misapprehension and confusion. In the absence of an official cadastre, the only reliable guide is the net rate of interest for capital, and even this must be employed with judgment. When either is ignored, the results can only be regarded as misleading.

**WEALTH OF NATIONS.** "In the year 1776, Adam Smith published his 'Wealth of Nations'; which, looking at its ultimate results, is probably the most important book which has ever been written, and is certainly the most valuable contribution ever made by a single man toward establishing the principles on which government should be based." Henry Thomas Buckle thus described the significance of the work of the eminent leader of the English school of "Classical Economists." While the exponents of the now popular theory of extensive state activity would be inclined sharply to differ with Buckle's estimate of the importance of the 'Wealth of Nations' as an expression of political and economic philosophy, there can be no doubt that this work was more effective than any other in producing the generally accepted political theory which dominated the mid-Victorian England in which Buckle wrote his 'History of Civilization in England.' Whatever may be the opinion of the modern social reformer with respect to the validity of Smith's individualistic and *laissez-faire* political theory, it is undeniable that a work which was able to shape the political and economic thought of a great European country, as well as of a considerable portion of continental Europe, for more than half a century is worthy of serious consideration by any student of the evolution of economic and political theory. Inasmuch as Smith's major work involved a treatment of both political philosophy and economic theory, it may increase the clarity of this summary

to treat these two phases of his doctrine, though always remaining constant in Smith's mind they formed a unified and coherent body of thought.

political theory Smith followed the of Locke, Montesquieu and Hume, with the doctrines of the Physiocrats the proper scope of state activity. It coincides with the latter which is of importance in this analysis, as he here receives his greatest influence. Accepting the doctrine which the Physiocrats had taken over from temporary scientists and *philosophes*, that there is a natural and beneficent order which pervades the universe and of which the political phenomena—an order which cannot and therefore should not be altered—Smith launched a violent attack upon the restrictive state activity which was advocated by the Mercantilist writers and which dominated political and economic thought and practice for more than a century and a half (1776). It was his fundamental thesis that the greatest happiness and the "wealth of nations" can be most rapidly and effectively increased by bringing about complete industrial and commercial liberty, and it was at this point that his political philosophy merged with his economic theory and made possible a unified and coherent body of doctrine, though it grew up without any premeditation from separating politics from economics, as effectively as he had divorced politics from economics. Smith enumerates the duties of the state which it falls to a state to perform, or to guarantee the execution of beyond which it should not proceed are (1) the protection of the citizen against foreign states; (2) the administration of law and justice; (3) the establishment and maintenance of public works and the promotion of education, academic and religious. The state should have even the last two types of duties exercised as far as possible by itself, and should intervene voluntarily according to self-interest and the state should only intervene in emergencies when voluntary activity fails to perform in an effective manner. It is needless to say that he vigorously urged the immediate abolition of all restrictive state regulation of industry and commerce and the immediate institution of that régime of unhindered competition which would allow economic affairs to develop in accordance with the beneficent order of nature and the full measure of happiness and well-being to the human race. These *laissez-faire* principles were adopted and re-emphasized by his disciples and were the leading factor in the development of that abolition of industrial and commercial restrictions which constituted that "economic liberalism" and "political independence" which was the most fundamental characteristic of the economic and political history of the first half of the 19th century and which still prevailed a century after the publication of the 'Wealth of Nations'.

strictly economic doctrines Adam Smith had as wide an influence as through his political theories. Though not the founder of political economy, he was its first systematizer, and the 'Wealth of Nations' laid the foundation of modern economics in much the

same way that Comte's 'Positive Philosophy' does to present day sociology.

The most conspicuous element in Smith's system of economic doctrines was his emphasis upon the factor of *labor*, which he conceived to be the ultimate source of all wealth and the true measure of value. In his theory regarding the production of wealth his emphasis upon the importance of the division of labor has been most influential in the history of economic thought. Smith's treatment of this subject was the first extensive analysis it had received since the appearance of the 'Republic' of Plato, and in many respects it has never been improved upon. Smith's analysis of value and exchange is centred about the well-known labor theory of value, and he maintained that the actual measure of value was the quantity of labor which a given commodity would command in exchange. His theory of distribution initiated the conventional discussion of wages, profits, interest and rent. Wages are the return to labor and are determined by the demand for, and the supply of, labor. Profits are the return to capital and are determined by the amount of capital stock invested, varying inversely in proportion to the amount of the stock. Interest is that part of profits which is derived from the lending of capital. Finally, rent, and here in part he anticipated Ricardo, is the return to the landowner and may exist as soon as all free land is occupied. It normally equals the residue from the gross income of the renter after he has deducted profits and wages. Though these specific phases of economic analysis in the 'Wealth of Nations' were of great importance for the subsequent development of economic theory, they have scarcely stood the test of more refined and scientific analysis, and they have done far less than his more general contributions to secure for Adam Smith the pontifical position which he still occupies in the history of economic thought. This position has been attained by his epoch-making attack upon Mercantilism; the accompanying advocacy of the initiation of the régime of *laissez-faire* and unhampered industrial competition; and his production of the first great systematic treatise on political economy. The significance of the 'Wealth of Nations' for posterity has been thus expressed by Walter Bagehot, "The life of almost every one in England—perhaps of every one—is different and better in consequence of it. No other form of political philosophy has ever had one-thousandth part of the influence on us." Consult Gide and Rist, 'History of Economic Doctrines' (Chap. II); Haney, L. H., 'History of Economic Thought' (Chap. X); Bonar, 'Philosophy and Political Economy' (pp. 146-183). The relation of the 'Wealth of Nations' to sociology is presented in A. W. Small's 'Adam Smith and Modern Sociology.'

HARRY ELMER BARNES,  
Professor of History, New School for Social Research.

**WEANING**, the accustoming of an infant to food other than its mother's milk, or the disengaging of a child from the habit of nursing. In normal cases it is now deemed desirable to continue nursing for nine or 10 months after birth. Very careful mothers extend the period to cover the second summer. With

children who are healthy, and cut their teeth early, weaning may begin earlier than with weak, sickly children. It should never be attempted during sickness, nor, unless absolutely necessary, in hot weather. It is best for both mother and child to bring it about gradually. By so doing the secretion of milk in the former is slowly diminished, and those complaints which arise from sudden weaning are prevented; while the child is gradually accustomed to other kinds of sustenance, and the restlessness and want of sleep, which are so troublesome in sudden weaning, are avoided. Both during the weaning and for some time after it no food should be given to the child except what is very easy of digestion, and more fluid than solid, and in particular what has no stimulating qualities, nor any that will tend to create acidity, or produce other marked changes in the organic function. See INFANCY.

**WEARE, wār, Meshech**, American colonial leader: b. Hampton Falls, N. H., 16 June 1713; d. there, 14 Jan. 1786. He was graduated at Harvard in 1735; studied theology and entered the ministry, which he gave up for the practice of law; was repeatedly sent to the legislature, and in 1782 was speaker. His later appointments included that of commissioner to the Albany Congress (q.v.) in 1774, justice and (1777) chief justice of the Superior Court of Judicature. He was also colonel of a militia regiment, and when the Revolution opened was appointed chairman of the Committee of Public Safety. Upon the reorganization of the State judiciary he was placed at its head. He raised troops for defense against Burgoyne, whose invasion he materially aided in repelling. In 1776, under the temporary constitution, he was elected president of the State, and was annually re-elected until 1784. Under the new constitution he was again elected president, but resigned before the expiration of his term.

**WEASEL** (*Putorius noveboracensis*), a fur-bearing mammal (q.v.), typical of the family *Mustelidae*. The body is elongated and slender, the head long, the legs short, the muzzle rounded and the tail short and slender. The feet have each five toes and are digitigrade and unwebbed. There are 34 teeth and the sectorial or flesh-tooth lacks an internal tubercle. The anal glands are developed and secrete a strong-smelling substance. The weasel attains a length of from 12 to 15 inches, of which the tail makes nearly one-third. The male is larger than the female. Above, the color is brown; below, white or pale yellow, the terminal one-third of the tail black. In winter the fur becomes more or less white, but this change is complete only in the north and does not affect the black of the tail; in this white phase the animal is called an ermine (q.v.). The common weasel, in one or other of its varieties, inhabits the entire eastern United States, westward to Minnesota, south to North Carolina and north to Canada; and is replaced in most other parts of North America by more or less closely related species and in Eurasia by others, of which the Siberian ermine is its nearest ally. Owing to its retiring and nocturnal habits it is unknown to most people. It is plentiful even in the vicinity of large cities, where it renders efficient service in the destruction of vermin.

The European weasel (*P. vulgaris*) is slightly smaller than its American relative, reddish brown in color, but whitish underneath. (See POLECAT). The weasel is a highly courageous animal, and makes war on rats, mice, hares and rabbits, birds and many other small animals. During the summer it devours insects, but appears never to partake of a vegetable diet. Instances are on record in which these animals have attacked horses and cows, and they sometimes exhibit an utter indifference to the proximity of man. They are especially fond of eggs, and rob hen-roosts and the nest of every wild bird which they find. Their mode of killing their prey is characteristic—since they usually fasten on to the neck of their victim, and hold firmly on while they suck the blood; next they eat the brains and only then the flesh. Like most of their near relatives they often kill much more than they require for food. They hunt by scent and are tireless in pursuit. Few animals are so active, and the slimness of their bodies enables them to explore every hole and hiding-place of their prey. Weasels live in holes under stone walls, rocks and trees, in burrows captured by force from ground-squirrels and woodchucks, in hollow stumps, etc. A nest of dried leaves and grasses is constructed and about five young are born in a litter. Consult Coues, 'Fur-bearing Animals' (Washington 1877); Merriam, 'Synopsis of the Weasels of North America' (Washington 1896).

**WEATHER**, the condition of the atmosphere, at any time in respect to heat, moisture, wind, rain, cloud and electricity; a change of weather implies a change in one or more of these elements. For the possibility and mode of making real predictions of the weather, see **STORM**; for the system of weather forecast, see **METEOROLOGY**.

The great changes of solar heating attending the alteration of day and night, and the annual march of the seasons, produce well-marked and predictable changes of weather in all parts of the world. There are indeed many tropical and sub-tropical regions of the earth where there is so much of regularity in several or all of the weather elements that the experience of preceding years forms a trustworthy guide by means of which the weather may usually be closely forecasted for a considerable time in advance. For example, the daily march of the barometric pressure at many tropical stations is so regular that the time of day can be told pretty closely by reading the barometer. But on the other hand, large irregular fluctuations of barometric pressure, rainfall and temperature prevail over a great portion of the earth, and in these regions there is as yet no sound system of local weather prediction for more than two days in advance.

The proximity of western Europe to the Atlantic makes it impossible in that region to predict the weather beyond a day or two at the utmost, except in the case of considerable storms leaving the American coast and likely, if not certain, to strike widely on the coast of Europe. In Norway and the Baltic, and places toward eastern Europe, the weather may be predicted for a longer time, owing to the more easterly situation. In America also, where storms advance chiefly from west to east, gales and unsettled weather are predicted for

on the seaboard in the east some days; though the course that a storm may whether more to the north or to the south, be certainly foretold.

forecast, conjectural indeed, yet often may be made by observing the barometric winds and the face of the sky—especially the cirrus cloud, most elevated and delicate of the clouds; but some previous knowledge of the general features of storms (q.v.) indispensable: these specially—(1) Storms a circular area, and (2) advance in any direction, bearing a low barometric pressure with them. (3) Winds blow from a low barometer—the observer, standing with his back to the wind, having always the barometer to his left in the northern hemisphere—and (4) with a force proportional to the difference of the pressure, or to the steepness of the barometric gradient. (5)

are noticed first in the upper regions of the atmosphere, or in the region of the cirrus. (6) In front of the storm the air is warm and humid; in the rear of it, cold, or even dry. With such observations, requiring a barometer intelligently interpreted, especially if hills form part of the landscape, the character of the weather may be foreseen on any day, or even on occasions longer. In general a falling barometer is not followed only by storm; but a rising barometer in the weather indicates the passing away of the storm, though, in the colder season, possibly without a change to higher winds and

to the agriculturist and horticulturist, not only winds but hails, heavy rains, frosts and other weather are what are required to be known. Such forecasts were begun in the United States by General Albert J. Myer; also introduced by Leverrier shortly before his death; and they are gradually being introduced throughout the continent of Europe.

The weather prognostics of every language are so much that is shrewd and of considerable value, but more that is vague and absurd. Changes of the moon long were, and in some minds still are, regarded as supplying elements of prediction; but when brought to a test of accurate examination and figures, the supposed influence of the moon's changes on the coming weather is found to be a delusion.

This was shown especially by an examination of 50 years' observations at Greenwich, and similar old records of the weather. For many years Thomas du Boulay predicted the general character of the weather of each summer from the weather conditions which prevailed during the week of the spring equinox preceding, supposing that the general character of the weather of the next six months is then settled, and requiring only skillful reading. For a few years he speculated in grain on the faith of his predictions, which turned out correct on a large scale; but later his predictions did not prove true. Many persons forget that a great deal of indiscriminately chosen instances are required for the verification of any theory of weather forecasting; and that more than a few, when impartially considered, will be favorable to the soundness of the theory, else the result is attributable to chance.

Within the past few years progress has

been made in two branches of experimental work, which may soon lead to marked advance in the line of forecasting. In the first place, the exploration of the upper air by means of kites and captive balloons carrying registering meteorological apparatus is yielding much knowledge of the distribution of atmospheric temperatures, currents and electrical conditions, which can hardly fail to promote the accuracy of storm forecasts.

In the second place, the work of the Smithsonian Astrophysical Observatory, begun under the direction of the late Secretary S. P. Langley, has tended strongly to show that the radiation of the sun (on which, directly or indirectly, all weather elements depend) is not constant, but varies often through a range of 10 or even 15 per cent in a few months. The connection between the temperature of the earth and the radiation it absorbs from the sun is such that a permanent decrease of 10 per cent in the latter would produce about 7° Centigrade (12½° F.) fall of the earth's mean temperature. But owing to the short period of the observed solar changes, and to the great capacity for heat of the oceans, the actual effect of the changes of solar radiation would generally be much less than this. Stations near the oceans will be only slightly affected, while stations in the interior of the great continents are apt to feel more nearly the full effect above estimated. On account of the secondary effects of changes of solar radiation upon cloudiness, and the reaction of cloudiness on temperature, the temperatures of different stations will be differently influenced. Owing to the immense size of the sun a considerable time must elapse before conditions affecting its radiation can reverse, and thus it seems highly probable that when the exact connection between the changes of solar radiation and the weather has been determined, it will be possible to predict the prevailing characteristics of a season, whether cold or hot, wet or dry, for some weeks, and perhaps one or two months in advance. See CLIMATE; METEOROLOGY; RAINFALL.

**WEATHER BUREAU.** The invention of the electric telegraph made it possible to apply the developing science of meteorology to the art of weather forecasting. While American scientists were pioneers in the development of the knowledge of the atmosphere, the United States was not the first government to organize a weather reporting service, but it was the first to do so on a large scale. Its broad expanse of territory permits it, with the aid of simultaneously taken observations at over 200 stations, to chart and study the operations of several different storms at the same time, and to forecast their movements through two or three thousand miles of their progress eastward. Warnings of frosts, cold waves, floods, rain and snow storms, and of winds dangerous to mariners, are worth many millions annually, and the saving of human life is large. Forecasts cannot be made with mathematical accuracy, for they are practically all empirical deductions, but they do have such a high degree of verification that no one whose life or property is affected by the coming of severe storms would to-day consider for a moment doing without the benefit to be derived from them.

For many years the Smithsonian Institution

was the custodian of meteorological observations collected from government officials and others by mail, and Prof. Joseph Henry, Secretary of the Institution, in 1858, was the first person in this country (probably in the world) to collect by telegraph simultaneously taken weather observations and daily plot them on a publicly displayed map. Except in a tentative way, it does not appear that forecasts were made from these maps. He demonstrated, however, the feasibility of a national weather bureau, such as Dr. Increase A. Lapham, of Wisconsin, had diligently advocated for many years preceding, and such as Maury had suggested as the result of his studies of the storms of the oceans, and as Redfield had recommended in 1846.

Henry's map was discontinued with the breaking out of the Civil War, after having been in operation but a short time, as was a weather report issued by Prof. Cleveland Abbe, at Cincinnati, in the fall of 1869, with the aid of the Western Union Telegraph Company and the Cincinnati Board of Trade.

The persistent study of Lapham in taking comparative observations with Dr. Asa Horr, of Dubuque, Iowa, in 1853 and in 1860; the publishing of results in the *Milwaukee Sentinel* in 1861, showing, as Jefferson and Madison had done for Virginia many years before, that weather changes also progress from the west in the Mississippi Valley; his work in collecting and compiling records of the loss of life and property on the Great Lakes due to storms, and his petitions to scientific, commercial and legislative bodies, was mainly and immediately responsible for the resolution introduced in Congress by Gen. Halbert E. Paine, of Wisconsin, in 1870. This finally initiated a government weather forecasting system in the United States that has grown to be the largest of its kind in the world and more intimately to serve the people than does any other.

Gen. Albert J. Meyer, U. S. A., the first chief, a man of splendid executive attainments, so wisely laid the foundations of the new and unique service and so successfully demonstrated its value to the industries of the nation, that Congress readily gave the appropriations necessary for its growth and development. General Meyer at once called to his aid Dr. Lapham and Professor Abbe. Lapham did not wish to leave Wisconsin permanently, where he was considered one of the most useful citizens of the State, but he did service for a time at Chicago, where he made the first government weather map and issued to the public the first government forecasts, then called 'probabilities.' Professor Abbe accepted service and became a scientific aid to the chief in Washington, which position he held continuously until the day of his death in 1916.

Until 1891 the weather service was a part of the Signal Corps of the Army, and the chiefs were, in the order of service, Gen. Albert J. Meyer, Gen. Wm. B. Hazen and Gen. A. W. Greely. It then became a bureau in the Agricultural Department, with Prof. Mark W. Harrington chief. Harrington served four years, and was succeeded by Prof. Willis L. Moore, who directed its affairs for 18 years. The latter was followed by Prof. Charles F. Marvin, the present chief.

**How a Weather Map is Made.**—Each morning at eight o'clock, 75th meridian time—which, by the way, is about seven o'clock at Chicago, six o'clock at Denver, and five o'clock at San Francisco—the observers at 200 stations distributed throughout the United States and the West Indies take their observations, and, with the aid of carefully tested instruments, note the pressure of the air, the temperature, the humidity, the rainfall or snowfall, and the cloudiness. During the next 40 minutes these observations are speeding to their destinations, each station contributing its own observation, and important stations receiving in return such observations from other stations as they may require in the making of maps and forecasts.

At the Central Office in Washington as fast as the reports come from the wires they are passed to the Forecast Division, where a force of clerks is engaged in making representations of the geographical distribution of the different meteorological elements. One clerk constructs a chart showing changes in temperature during the past 24 hours. Broad red lines separate the colder from the warmer regions, and narrow red lines enclose the areas showing changes in temperature of more than 10°.

A second chart shows the changes that have occurred in the barometer during the past 24 hours. As in the construction of the temperature-change chart, broad lines of red separate the regions of rising barometer from the regions of falling barometer. Narrow lines enclose the regions where the change has been greater than one-tenth of an inch; inside of these lines other lines enclose the areas where the fall has been two-tenths, and so on. Here, for instance, throughout a great expanse of territory, all the barometers are rising—that is to say, that throughout this region the air is cooling and contracting, and therefore allowing that of adjacent warmer regions to flow in at high levels. Thus the total quantity of air resting on any given area at the ground is increased, and hence the barometers stand correspondingly higher. Over another considerable area the barometers are falling, as a result of the air above them flowing away to cooler regions. This chart indicates whether or not the storm centres are increasing or decreasing in intensity, and it gives, in a great measure, the first indications of the formation of storms.

A third chart shows the cloud areas, with the kind, amount and direction of clouds at each station.

A fourth chart, called the general weather chart, shows for each station the air temperature and pressure, the velocity and direction of the wind, the rain or snowfall since last report, and the amount of cloudiness. This is the principal chart from which the forecaster makes predictions. The readings of the barometer on this chart are reduced to sea-level, so that variations in pressure due to local altitudes may not mask and obscure those due to storm formation. Then lines, called isobars, are drawn through places having the same pressure. By drawing isobars for each difference of pressure of one-tenth of an inch the high- and the low-pressure areas are soon enclosed in their proper circles. The word "high" is written at the centre of the region of greatest air pressure.

word "low" at the centre of the region pressure. The air flows from a region pressure toward one of less, the velocity upon the difference in pressure in distance.

arrows fly with the wind, and, as will be by reference to any weather map, are without exception moving indirectly toward the low or storm centre, and outward from the high.

A weather map is made every 12 hours, and in severe cold waves, dangerous marine heavy snows or floods are threatened, reports are ordered to be sent to the Centre every four hours from the danger and some distance to the east of it. The frequent use of the telegraph and telephone, and by maps and bulletins, and other agencies, every community in the United States is warned of impending changes that may be dangerous to it or to its interests.

The work of the Central Office of the Bureau is divided between several administrative divisions, the chiefs of which direct various branches under the supervision of one of the whole service. The Forecast Division receives and charts the telegraphic reports sent in twice daily, and several

are sent from restricted areas when danger conditions are imminent. It issues all the important warnings for the whole country to facilitate getting to the public forecasts in the shortest possible time, disseminators receive full sets of reports at Chicago, New Orleans, Denver, San Francisco and Portland, Ore., and simultaneously with the Central Office, make and disseminate forecasts for definite districts, but these centres are instructed from Washington to forward to each of the important warnings

issued. Certain river centres issue forecasts of the daily stages of the rivers in their respective regions independent of the Central Office. Local forecasters at all of the important stations issue forecasts for their vicinities and in freedom of expression, provided they first forward from Washington forecast each for his district. In addition to the 200 regular observations of the bureau there are some 200 observations at lake and sea ports that display the day and night lights to warn of storms. Special means of distribution are provided so that warnings of frosts, heavy rains, floods and marine storms may be reached all of those who may profit by

The River and Flood Division has charge of that part of each local station which furnishes information as to precipitation and amount of snow and ice on the ground and the water-sheds of the principal rivers and the measuring of the height of

For this purpose, in addition to 48 stations, where gauge readings are made, there are over 250 special stations that measure the height of rivers and 74 that measure

the duties of the Division of Agricultural Meteorology is to supervise the work of 3,000 voluntary or co-operating observers, who serve the public and render reports of temperature, precipitation and other miscellaneous meteorological

and climatic data, which are published in the *Monthly Weather Review*. There is thus being collected a large amount of data that is available for the discussion of climate in its relation to man from either a hygienic or a commercial viewpoint. During the seasons of planting, cultivating and harvesting, weekly reports of weather conditions and their effects upon various crops and farming operations are included in both the national Weekly Crop Bulletins and in 42 section bulletins. This division controls the distribution of the forecasts and warnings issued by the Forecast Division.

The Instrument Division is charged with the examination, testing, comparison, installation and maintenance of the instrumental equipment of the bureau.

The Division of Meteorological Records has charge of the compilation of meteorological and climatic statistics and their application to the various needs of commerce, courts of law and individuals.

The Division of Barometry and Aerial Exploration has charge of the exploration of the upper air by means of kites, balloons, theodolites and nephoscopes. It studies the technical problems of air pressure and vapor-tension.

There are also the Publications, Telegraph and Supplies divisions, the duties of which are indicated by their respective titles.

The observation instruments consist of standard wet, dry, maximum and minimum thermometers and the mercurial barometer, for measuring temperature and pressure, with wind vane and anemometer for wind direction and velocity. Most stations are also equipped with self-registering instruments that record continuously the fluctuations in pressure and temperature, velocity and direction of the wind and the number of hours of sunshine. An automatic rain gauge also registers the time of beginning and ending of precipitation, together with the amounts that occur.

The telegraphic circuits are so arranged that at any station those reports are taken off that are used in making charts and forecasts at that station. The observation messages take precedence over all others and the efficiency of the telegraph companies is such that within an hour after the observations are taken they all have been received at Washington and other stations.

The press associations receive the forecasts as soon as made and immediately furnish them to the papers to whom they render service. They are also telegraphed to Chambers of Commerce, or delivered by messenger from the local office of the bureau to the commercial associations and marine agencies, where they are posted on bulletin boards. Before the more important commercial exchanges an observer of the bureau each morning draws the weather chart in different colored chalks, on a glass map of the United States of about 8 by 12 feet. The principal stations of the bureau are equipped with plants for the printing of the daily weather map and forecast cards, which are distributed by messenger and post. The forecasts are also telegraphed to a large number of postmasters, who stamp them on cards that are mailed to surrounding towns.

For a number of years the bureau maintained at Mount Weather, Va., a research

station, through the work of which the United States co-operated with other nations in the gaining of useful information of the great ocean of air above us. Up to 1912 the records of the world were broken at this institution, altitudes of four and one-half miles being attained with kites carrying self-recording instruments and balloons ascending to over 19 miles. The latter was accomplished by sending instruments and balloons to the far west, where they were liberated, the instruments descending to the earth farther east under parachutes after the balloons had burst. The exploration of the upper air made by this institution has proved of inestimable value to our aviators during the World War, an elaborate series of observations, or deductions thereupon, covering a period of five years, having been published by the National Advisory Committee for Aeronautics.

**Further Development in Forecasting.**—We reasonably may expect that it is but a matter of time and not far in the future, when enough of the observation stations of the bureau will be equipped with kites for windy days and aviators for days of moderate wind, so that there may be secured such a system of simultaneous observations as will enable the forecaster at Washington to construct a weather chart on say the three-mile level, which is about in the centre of storms, so far as their vertical dimensions are concerned. By comparing such a chart with the sea-level chart a much more accurate forecast surely can be made. At the close of the war many thousand air men were free for the development of mail, passenger and light freight transportation through the air. Then forecasts of the stability of the air for flight became imperative. The proposed high-level chart will render such forecasts possible. The time may be near at hand when Weather Bureau stations will display more warning signals from the tops of their office building and elsewhere for the benefit of air sailors than are now displayed to aid the sailors of the sea.

Ignorance of weather conditions on the oceans costs the world hundreds of millions of property annually and the toll of human life is appalling when expressed in figures. To aid in preventing this enormous loss, much of which is unnecessary if the full measure of the methods that science within recent time has put at our disposal is utilized, the writer, as chief of the Weather Bureau, organized a system of wireless observations from moving ships along the Atlantic and Gulf coasts that has enabled the forecaster to detect many hurricanes when they were entirely out of the range of our land stations and give full and timely warning of their approach. In 1912 he formulated and published a plan for the construction of a daily weather map of the Atlantic Ocean by the relay from ship to ship of simultaneous observations and their charting at the Central Office of the Weather Bureau in Washington. With only two-words in the message the location of the ship and the reading of the barometer can be conveyed. When the pressure of the air is plotted the direction and force of the wind will be known. The storm regions can be shown, and when hurricanes appear no ship carrying a receiving instrument

need be unadvised of its location, for a power message can be flashed from some wireless station which will, at the same reach every vessel on the great ocean.

The first thing necessary to the institution of the proposed great ocean service—right of way for messages, so that they be quickly accumulated at some cent—With the object of overcoming this the writer was made a member of the national Radio Congress that met in L. in 1912, where, with the aid of the States delegates, he secured the adoption of regulations that give to the observatories needed in such a service the right to intercept all messages except distress calls. The logic of events must eventually compel the adoption of something so necessary to the welfare of humanity, both on the Atlantic and Pacific oceans. The return of our flag to peaceful ways of ocean commerce and the protection of our fleet in time of war, would require the proposed extension of the domain of the Weather Bureau.

Seasonal forecasts also seem to be one of the possibilities of the future. Abbot, Hall and other able men are studying the variations in solar radiation, the recurrence and frequency of sun-spots and solar prominences, hoping by a comparison of data to trace a relation between them and the ever-varying seasons of the earth. Recent results are encouraging.

**WEATHER SIGNALS.** See SIGNALING.

**WEATHERFORD, William,** / half-breed Indian chief: b. Creek Seminoles, Ala., about 1770; d. Monroe County, Ala. He was the son of a white trader and Seminole Indian woman. He was a warrior of great bravery and force of character. He was killed at the attack upon Fort Mims, 30 Aug. 1813, defeated by Claiborne at the battle of Red Bank, December 1813; and again suffered defeat at Horseshoe Bend, 27 March 1814, after which he surrendered to General Jackson. He subsequently retired to his plantation, where he lived peaceably the remainder of his life. He was respected and honored by both Indian and white. Consult Parton, J., 'Life of A. S. Jackson' (Vol. I, 1860).

**WEATHERFORD,** weh'-er-förd, city, county-seat of Parker County, on a branch of Trinity River, and on the Gulf, Coast and Santa Fé, the Weatherford, Mineral and Northwestern and the Texas and Oklahoma railroads, 30 miles west of Fort Worth. It was settled in 1850 by persons from east and the older States. In 1856 it was incorporated, and in 1858 chartered as a city. It is an agricultural and stock-raising region. Wheat, cotton and corn are among the principal productions. The chief manufactures are flour mills, cotton mills, a cotton compress, a saw factory, machine shops and the light industries. There are 10 churches. The educational institutions are the Texas Female Seminary (Cumberland Presbyterian), the Weat-

WEAVER BIRDS (*Ploceus julianiani*.)

College (Methodist Episcopal South), a high school established in 1885, Saint Joseph's Academy, Hughey and Turner School, public and parish graded schools. There are three banks and three newspapers, one a daily. The government is vested in a mayor and a board of aldermen consisting of eight members. The majority of the inhabitants are American born; about 7 per cent are of Mexican and French descent and 3 per cent are colored. Pop. 6,500.

**WEATHERING**, the process, either mechanical or chemical, by which rock material is made fine and ready for removal by wind or running water. See **METAMORPHIC ROCKS**, and especially the section on the *Work of the Atmosphere* in the article on **GEOLOGY**.

**WEATHERLY**, weth'ér-lī, **Frederic Edward**, English song writer and barrister: b. Portshead, Somerset, 4 Oct. 1848. He was graduated from Oxford in 1871 and was called to the bar of the Inner Temple in 1887. He is widely known as the writer of popular songs, many of which have been given musical settings. Among them are 'Nancy Lee'; 'Polly'; 'Three Old Maids of Lee'; 'Darby and Joan.' Of his published volumes mention may be made of 'Muriel and Other Poems' (1870); 'Wilton School' (1872); 'Oxford Days' (1879); 'Rudiments of Logic' (1879); 'Questions in Logic, Progressive and General' (1883); 'Two Children' (1884); 'Lays for Little Ones' (1898).

**WEATHERLY**, Pa., borough in Carbon County, 18 miles southeast of Scranton, on the Lehigh Valley Railroad. There are manufactures of silks, machinery, woodwork, cigars and candy. Pop. 2,501.

**WEAVER**, wé'vər, **Aaron Ward**, American naval officer: b. District of Columbia, 1 July 1832. He was graduated at the United States Naval Academy in 1854; became lieutenant in 1855 and in 1858-59 cruised along the African Coast in the sloop *Marion*, and returned in command of the prize slaver *Ardennes*. He served in the Union army with distinction through the Civil War, was made commander in 1866, captain in 1876 and rear-Admiral in 1893; and was retired in September of the year last named.

**WEAVER**, Emily Poynton, Canadian author: b. near Manchester, England, 1865. She removed to Canada with her parents in 1880 and subsequently lived in Oxford County, Ontario, and in Halifax and Toronto. She is known as a writer of short fiction and historical essays for magazines, and is also author of 'My Lady Nell' (1890); 'The Rainproof Invention' (1896); 'Builders of the Dominion' (1907); 'The Trouble Man' (1910); 'Canada and the British Immigrant' (1914), etc.

**WEAVER**, James Baird, American political leader: b. Dayton, Ohio, 12 June 1833; d. Des Moines, Iowa, 6 Feb. 1912. He was graduated from Ohio University Law School, 1854, and began practice in Iowa. In 1861 he entered the Union army, was promoted colonel in 1862 and brevetted brigadier-general in 1865. In 1866-70 he was district attorney, second judicial district of Iowa, and in 1867-73 assessor of internal revenue first Iowa district. For some time he was editor of the *Iowa Tribune*, published at Des Moines. He took an active part in the organization of the Greenback party

and was elected to Congress on its ticket in 1879, serving one term; in 1880 he was the Greenback candidate for President, receiving over 300,000 popular votes. Later he was affiliated with the People's Party, was a delegate to the National Convention in 1892, and was again nominated for the presidency, receiving over 1,000,000 popular votes. Since 1895 he has lived in Colfax, Iowa, and was mayor of that city from 1903-06. He wrote 'A Call to Action' (1892) and 'Past and Present of Jasper County, Iowa' (1912).

**WEAVER**, Jonathan, American clergyman, bishop of the United Brethren in Christ: b. 23 Feb. 1824; d. 6 Feb. 1901, at Dayton, Ohio. His education was limited to the common schools and the Hagerston, Ohio, Academy. He first began to preach in 1845 but did not join a conference until 1847. After serving several appointments he became presiding elder in 1852 and then was agent for Otterbein University from 1857 to 1865 when he was elected bishop. In 1893 he became bishop emeritus. He was one of the greatest leaders of his church. He was the author of 'Discourses on the Resurrection' (1871); 'Ministerial Salary' (1873); 'Divine Providence' (1873); 'The Doctrine of Universal Restoration Carefully Examined' (1878); 'Practical Comment on the Confession of Faith of the United Brethren in Christ' (1894); 'Heaven, that Better Country' (1899); 'Christian Theology' (1900); Edited 'A Comprehensive View of Doctrinal and Practical Theology by thirty-seven different writers' (1889). Consult 'Biography of Jonathan Weaver,' by H. A. Thompson (Dayton, Ohio, 1902).

**WEAVER-BIRD**, a bird of the family *Ploceidae* remarkable for their nests. The family is a large one and is confined to the warmer parts of the Old World, Africa being particularly rich in species. Weaver-birds closely resemble large finches, with somewhat elongated bodies, moderate wings, which have the outer primary quill better developed than in the *Fringillidae*, long tails, and very bright plumage, the latter often varied in the breeding season. Yellow and yellowish red are the prevailing tints, but species occur in which black, red, white or gray predominates. The weaver-birds are extremely social, and many of the species live in large colonies during the period of incubation.

The nests of the various species differ considerably in shape and general structure, some (as the genus *Oriolinus*), building a separate nest for the male, while the female sits in another on her eggs, till relieved by her mate; others again contain more than one chamber, as that of the golden weaver-bird (*Ploceus galbula*); while the social weaver-birds (*Philæterus socius*) construct an umbrella-like roof, under which from 800 to 1,000 separate nests have been found. But in all cases fibres, slender twigs or blades of grass are the materials employed, the whole being tightly woven, after having been rendered more flexible and adhesive by the application of saliva. In some cases the birds of a pair take positions on opposite sides of the structure and the fibres are passed through and through from one to the other. The nests themselves consist of a more or less globular portion, elongated into a tube

below, with the entrance at the bottom or at the side. They are very generally suspended at the extremities of branches, and often over water, probably as affording security against monkeys, snakes and other enemies. The Mahali weaver (*P. talia*) is said to insert thorns into its nest, as a further protection against marauders. A Philippine species (*P. philippinus*) builds flask-shaped nests of fine roots suspended mouth downward by long ropes of similar construction from the boughs of trees. Consult Bartlett, 'Monograph of the Weaver-birds' (Maidstone 1888).

**WEAVERS, The.** The misery of the Silesian weavers of the second quarter of the 19th century inspired Heine to one of his most moving ballads and is a matter of common historical knowledge. Gerhart Hauptmann derived his intimate feeling for it chiefly from the lips of his grandfather, one of the actual sufferers; and in his work 'Die Weber' ('The Weavers') (1892) he has given to industrial revolution a stronger sanction than can be found in any other dramatic work whatever. 'Die Weber' is rather a series of five one-act dramas than a drama in five acts. Different groups of persons appear in five different places. But the persons belong to the same community, they pass to and fro, and the five acts, each a unit, with skilful exposition and a theatrical conclusion, constitute a greater whole, in which rebellion is carried to temporary success, but which is mainly impressive for the presentation of conditions that cry out for a remedy. There is no hero; every person is an integral character, every one a reality, and to the tragedy of starvation as the only reward for toil is added the pathos of vicarious atonement: an old weaver who refuses to leave his loom in order to join his fellows in rebellion is shot by a stray bullet. Hauptmann's method is unqualifiedly naturalistic. The play was first written in the harsh Silesian dialect, and the revised form in general circulation is only approximated to the literary language. It smacks of the soil. Its power resides in its apparent artlessness, in the impressiveness of truth naked and unadorned. There is, however, in a treatment of squalor which arouses unmixed sympathy a high degree of art, as there is also a preachment the more eloquent for being left to be inferred. Its text is the simple precept, give them their daily bread. Consult 'The Dramatic Works of Gerhart Hauptmann' (tr. by Ludwig Lewisohn and others, New York 1913-15).

WILLIAM G. HOWARD.

**WEAVING**, a process in which a series of longitudinal strands of fibre of one kind or another are united into a web or fabric by interlacing with cross threads. The two sets of threads employed traverse the web at right angles to each other. The first set extends from end to end of the web in parallel lines, and is commonly called the warp; while the other set of threads crosses and interlaces with the warp from side to side of the web, and is generally called the weft or woof. In all forms of weaving the warp threads are first set up in a device known as a loom, and then the weft threads are worked into the warp, to and fro, by means of a shuttle.

The art of weaving is of such extreme an-

tiquity that its beginnings cannot be traced, and, indeed, the idea seems to have had a high universal origin in the human mind. The essential methods are found in their developed form among savage tribes which have never been in touch with civilization. The primitive loom may have been no more than a simple beam suspended from the trunk of a tree and sustaining the warp fibres, the weft being worked in by hand with a shuttle or needle. But from the earliest times to the present it has been by this fundamental process of interlacing two sets of threads that all the fabrics of simple mechanism that all the fine fabrics have been produced—the cloths of Egypt, the fine damasks of Persia, the Greek and Roman muslins, the shawls of Cashmere, the world-famed weaves of Italy and the East.

Four classes of woven cloths are distinguished by weavers: (1) Single, or sim- ple, in which there is but one warp and one weft interlaced at right angles to one another. (2) Compound cloths, in which there are two or more warps or wefts interlaced at right angles to one another. (3) Cloths in which the warp threads are singly or in groups are interwoven with the weft threads during the weaving, with a knitting effect. (4) The pile fabrics of all degrees. This class includes all ordinary cloths of silk, wool, and cotton. The second class includes known as "hacked" cloths, two-ply, and four-ply fabrics, tapestries and plushes. The third class includes all the gauze type, or which are worked in the "leno" or knitting stitch. The fourth class includes such fabrics as Turkish towel cloths, velvet carpets, plushes and all descriptions.

The instrument or mechanism by which the operations of weaving are accomplished is known as the loom (q.v.). Looms are divided as Hand Looms and Power Looms. In the hand loom the operator throws the shuttle by hand, and works the treadles with his feet. In the power loom is automatic, all necessary operations being carried out by ingenious and delicate mechanisms, so that once started it weaves until all the warp has been woven into cloth. An attendant stands by to attend to the loom in case of accident, and usually one operator is required to several running looms.

**Hand Looms.**—Until comparatively recent times all weaving was effected by the hand loom. This loom, in its usual form, consists of a frame of four upright posts held together by cross-beams, a centre beam at the back being the warp beam, and a front beam being that upon which the weft threads are worked while just below this, in front, is a beam for the support of the weaver. At the top of the loom is an apparatus by which the heddles are lifted or kept down. These heddles consist of vertical frames with cords, each with an eyelet at the top. In "setting" the loom the mass of the warp threads is wound upon the warp beam as upon a spool. They are then drawn by one to the heddles. If there are many heddles on the loom, as in plain we-

threads are passed alternately through the eyelets; that is, the first, third, fifth—and all the other odd-numbered threads through one heddle, and the even-numbered threads through the other. A loom may have many heddles, as in pattern weaving and in that case the threading of the warp through the heddles requires much

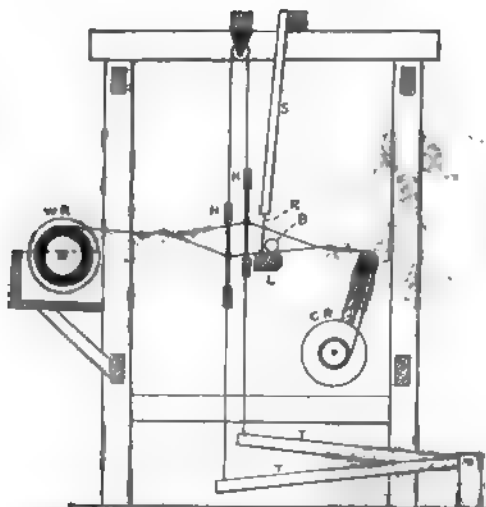

FIG. 1.—Sectional Diagram of Hand-loom W.R., Warp beam; C.R., Cloth beam; H, B, Heddles; T, T, Treadles; L, L, L, Reed; B, Bobbin; S, Swords.

skill, to be gained only by experience. After passing the heddles the threads are brought forward through the reed, a sort of comb-like structure with long teeth, lying upon its back, the teeth extending vertically upward. Two adjoining warp threads pass in the space between each two teeth of the "comb." The ends of the warp are finally fastened to the cloth-beam in front. Care is needed in order that all the threads shall have equal tension, so that the cloth when woven shall be smooth, and not pucker. Attached to the lower edge of the reed is the "ley" or "sley" which serves to weight the reed and thus give force to its blow in the weaving process, and also provides a shelf along which the shuttle travels. See Fig. 1.

In the operation of the loom, when one heddle is raised every second thread in the warp is also raised, while the remaining threads are depressed; and this is called shedding the warp. When the warp threads are thus parted there is left a small opening or shed between the threads directly in front of the reed, and it is through this opening that the weaver drives his shuttle to and fro, from side to side. The shuttle, which is hollow in the middle, contains the weft-thread wound around a bobbin or pin, and as the shuttle is shot across the web this weft-thread unwinds itself. When the thread is thus introduced it is necessary to bring it to its place in the fabric. This is accomplished by means of the ley or batten, suspended from a pivot at the top of the loom, swinging backward and forward like a pendulum by an attachment of vertical rods at each side called the swords. The teeth of the reed are thus swung forcibly against the newly laid weft thread, driving it solidly to its place in the cloth. The other treadle is then pressed

down, raising the other heddle and, with it, the alternate warp threads, thus forming another shed, in which the threads which were the floor of the first shed are the roof of the second. Through this new shed the shuttle is thrown on its return journey. This throwing of the shuttle is termed "picking" and each traverse of the web is called a "pick." The travel of the shuttle is accomplished by means of a Y-shaped handle, to the arms of which are attached two strings which lead one to each of the shuttle boxes at the ends of the ley. A quick jerk upon the string sends the shuttle flying out of its box through the shed of warp threads and into the shuttle box at the opposite end of the ley. Thus the weaving proceeds, the ley being swung forward, driving up the new weft thread, after each pick of the shuttle. Occasionally, as the web of finished cloth increases, the loom is stopped, and the cloth is wound up around the cloth-beam, another stretch of warp being unwound from the warp-beam; and this succession of operations continues until the entire length of the warp has been woven into cloth.

**Weaves.**—There are three fundamental methods or plans of interlacing the warp and weft threads in weaving; (1) plain weave; (2) twill weave; and (3) sateen, or satin weave. All woven cloths may be referred to one or another of these three primary plans or of a combination of two or more of them—in which case the texture is called "combination weave." By far the larger part of all woven fabrics is produced by the plain weave method, but these cloths are varied in many ways—by modifications of the relative sizes of the warp and weft threads, by manipulations of the heddles, and to an unlimited degree as to the color and design by the use of self-colored and parti-colored threads in both weft and warp.

**Plain Weave.**—In plain weave the threads are made to interlace alternately; and, if the warp and weft threads are of the same diameter, and there are an equal number of each to the inch, they bend around one another to about the same degree, and thus form a plain flat uniform cloth, in which the warp and weft threads

FIG. 2.—Simple Weave, showing the interlacing of the warp threads A, A, with the weft thread B, B. At right the weaver's pattern for simple weave with the tie-up of the two heddles employed (above).

appear equally on the surface. With this weave are produced the finest cambrics and muslins, and the heaviest woollen blankets—and the numberless other fabrics of similar texture lying between these two extremes.

A diagram of the interlacing of plain weave fabrics is shown in Fig. 2, the threads A,

A representing a section of the warp, and the continuous cross-thread B, B representing the weft. In actual weaving the warp threads would lie close together, usually from 16 to 64 to the inch, and each pick of the weft would be driven up snugly to the one preceding by a blow of the reed. In order that the weaver may know what style of cloth he is to produce, a plan or pattern is drawn for him by the designer on paper ruled in squares; the latter being marked in some way to indicate the position the thread represented will occupy in the finished cloth. The rows of squares running vertically indicate the warp, and those horizontally the weft. As only the warp threads are raised and lowered by the heddles, the pattern is made to indicate these movements by coloring the squares.

Ordinarily (though the exact reverse is sometimes encountered), a blackened square shows that that section of the warp is depressed below the weft thread on that pick. It is also customary to show the threading of the heddles above (or below) the pattern—as shown in the figure. The two heavy horizontal lines indicate the bars of the two heddles used in plain weaving; the upright lines leading to the heddle bars from the pattern indicate the method of threading each strand of the warp.

Fig. 3 shows a diagram of the arrangement

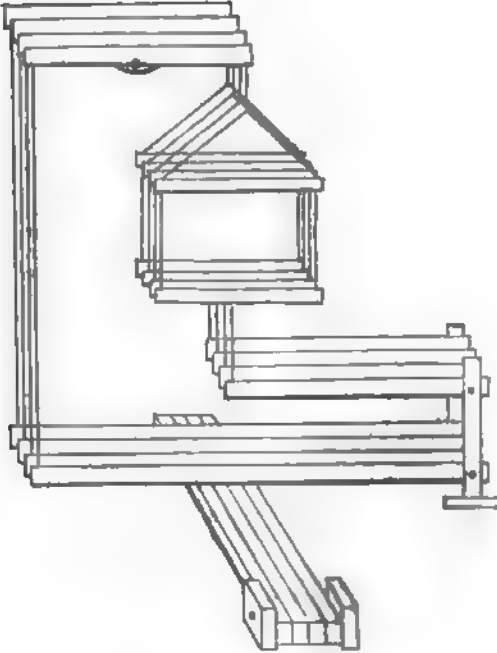

FIG. 3.—Diagram of Attachment of Heddles to Treadles for Double Shed Motion.

of levers where both the rising and sinking of the warp threads are employed in producing the shed. The short horizontal levers are so tied to the long ones that when one of the latter is depressed by stepping upon a treadle, thus raising one of the heddles, all of the other heddles (three in this case) are pulled down, producing the double movement shed shown in profile in Fig. 1.

Modifications of the plain weave may be

made in several ways; for example, by in two or more threads of the warp each pick of the weft, thus extending the weft from side to side, or a form of pattern is designated, in the "zonal" form. Or two or more threads of warp may be passed under by the weft in successive picks without change of the he thus exposing more of the warp than is in simple plain weave, thus forming a "cal" pattern. Plans for both these patterns shown in Fig. 4. Such modifications m

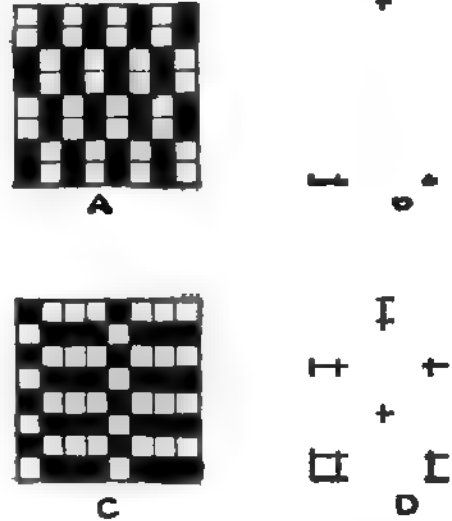

FIG. 4.—Plain Weaves. A, Vertical pattern; B, Horizontal pattern; C, Horizontal 1-and-3 pattern; D, Weave.

uniform, or they may be uneven in diameter, that is, the same number of threads may be taken in at each stitch, or there may be a constant variation, as 1-and-3, 1-and-3, and so on. If the same number (more than one) are both vertically and horizontally the "chessboard" weave is produced. Plans for these are shown in Fig. 4.

**Twill Weave.**—In the weaving of twill interlacing is quite different from plain weave. Considering the shuttle as starting from the left hand, and the threads numbered consecutively from left to right, the operation is described thus: for the first pick the first thread of the warp is raised, allowing the shuttle to pass under it, the second and third threads being depressed so that the weft lies above them; the fourth thread is raised and the fifth and sixth are depressed—and so on; on the second pick, that is, as the shuttle comes to its first position, the heddles are adjusted so that the second thread of the warp is raised, the third and fourth being depressed; the fifth is raised, and the sixth and seventh depressed and so on. As the shuttle starts away from the left, the first and second threads are depressed and the third raised, the fourth is depressed and the sixth raised—and so on; thus completing the cycle. By this method of manipulating the heddles is produced the diagonally ribbed appearance of the surface of the cloth characteristic of twills. These

blings appear on both sides of the cloth. They may trend either to the right or to the left (from the weaver). On the three-thread pattern, as described above, only one variety of twill can be produced—that with the apparent ribbing on the diagonal of a square, that is, at 45°. But by using a four-thread pattern—that is, by depressing three threads of warp

FIG. 5.— Cross Sections of Single Weave Cloths: A, the common weave with weft and warp of equal size; B, corded or repp cloth with two sizes of warp; C, 1-and-3 cloth.

for each one raised, a modified twill is produced with a “flatter” diagonal, that is, at about 30°—away from the weaver. The cloth thus produced is called a “horizontal twill.” On the other hand the manipulation of the heddles may be such that three vertical measures of the warp may be left on the surface to each one covered by the weft, thus producing

FIG. 6.— Pattern for Plain Weave on two heddles; showing tie-up above, and treadle movement at the right.

a “vertical twill,” with the angle of the ribbing running away (from the weaver) at about 60°.

Where four threads (of warp) and four picks (of weft) enter a design a much wider variety in texture is gained. In fact, next to the plain weave the 2-and-2 twills are the most extensively used in weaving; constituting the serges, cassimeres, most linen goods and a

great variety of silk, wool and cotton dress cloths. Patterns of the three fundamental straight twills on four threads are shown in the upper tier of Fig. 8, the 2-and-2 twill in the centre; the tier of pattern blocks just below them showing the reverse sides of the upper

FIG. 7.— A, Regular twill; B, Vertical twill; C, Horizontal twill.

blocks. Besides these straight twill weaves three other arrangements are possible through the manipulation of the heddles in an irregular fashion, thus producing what are called “broken twills”—used very largely in the weaving of the coarser lines of “dice” pattern; in many

FIG. 8.— Group of Four-thread Twill Patterns.

woolen cloths; in double-faced cloths; and extensively as a base for various fancy weaves and for dotted fabrics. Patterns for these broken twills are shown in the lowest tier of Fig. 8. The twill weave can also be carried into five-thread patterns, and even greater skips,

FIG. 9.— Patterns of Herring-bone Twills.

but with five threads the sateen weave becomes available, and is more commonly used. It is obvious that the direction of the ribbing in a twill may be changed at will from a right-hand trend to a left-hand trend during the process of weaving, and thus produce a zigzag pattern

known as "herring-bone" or diaper—as shown in Fig. 9. In Fig. 10 is shown an elaborate pattern of twill which may be worked on 10 heddles and with 10 treadles. One of the chief advantages of the twill pattern is that a firm and substantial cloth may be thus woven from comparatively light yarns.

**Sateen Weave.**—In sateen weaving at least five heddles are used. Supposing the shuttle to start from the left side of the warp, and the

sateens: 3-and-5 and 5-and-3. In an thread design eight different sateens are possible: 2-and-9, 3-and-8, 4-and-7, 5-and-6, 6-and-5, 7-and-4, 8-and-3, 9-and-2. As a practical limit in designing it may be mentioned 24-thread patterns are in use for fine though rarely for other materials.

**Damaska.**—In damask weaving the pattern is produced by arranging that the warp in some parts of the fabric and the weft in o-

FIG. 10.—Pattern of Twill Weave on ten heddles; showing tie-up above, and treadle movement at the right.

warp threads to be numbered consecutively from that side, the operation may be described as follows: the first, sixth, 11th, etc., threads are stitched on the first pick; the third, eighth, 13th, etc., on the second pick; the fifth, 10th, 15th, etc., on the third pick; the second, seventh, 12th, etc., on the fourth pick; and the fourth, ninth, 14th, etc., on the fifth pick—thus completing the sateen cycle. The resulting fabric is of peculiarly pleasing texture, displaying comparatively long stretches of parallel fibres, affording a smooth and silky texture.

On five threads and five picks only two patterns of regular sateens are possible. These are indicated at A and B in Fig. 11. Variations are produced by increasing the number of threads or picks in each stitch; thus producing patterns C and D in the same figure. Further variations give patterns E, F and G. It is readily seen that no regular sateen pattern can be worked out on six threads (each way). With seven threads, however, there are four; expressible by the leaps in the stitches, thus: 2-and-5, 3-and-4, 4-and-3, and 5-and-2. In an eight-thread design there can be only two

shall be exposed in more or less solid. This form of weaving is employed generally in textiles of cotton, linen and wool, though sometimes in wools and silks. Well-known examples are table linens and holsters. The stitch is usually of four or eight-thread sateen. In the case of napery the ground work is usually of four or eight-thread sateen, and the figure in eight-thread sateen. In fine fabrics may show up to 140 and 200 picks of weft to the square inch. The illustration of damask texture is given in Fig. 12.

The possibility of combining the damask and sateen weaves in the production of "combined" textures has been referred to. The necessary limits of an article such as this preclude a discussion of these numberless variations, and the student must be referred to technical works cited in the bibliography at the close of the article.

**Jacquard Loom.**—A most important improvement was made on the handloom by the Jacquard of Lyons, who, in 1801, invented an apparatus by which the most intricate

could be woven as readily as plain cloth. This is accomplished by an ingenious arrangement of hooks and wires, by means of which the warp threads are lifted in any order necessary to make the shedding required by the pattern. The order in which these hooks and wires are suc-

FIG. 11.—Group of Saten Weave Patterns.

cessively lifted and lowered is determined by means of a series of pasteboard cards punctured with holes, the holes corresponding to a certain pattern and the cards passing successively over a so-called "cylinder," of square cross-section, over which the chain of cards is carried. With

FIG. 12.—Pattern showing method of weaving damask.

each pick of the shuttle this "cylinder" swings outward and makes a quarter-revolution presenting a new card face on the return swing. The wire rods which fail to strike a hole in the card are driven back thus unhooking the hooked rods from the rising and falling "knife

beam" which operates the heddles. The hooks which remain on the pins of the knife beam lift the warp threads to which they are attached to the "roof" of the shed. The unhooked threads remain on its "floor." The operation will be more readily understood by referring to Fig. 13. When the pattern is extensive the machine may be provided with as many as 1,000 wires.

**Power Looms.**—A great development in the art of weaving followed upon the invention of the power loom by the Rev. E. Cartwright in 1784. In the power loom, which has been gradually improved and adapted to steam and electric power, the principal motions of the old method of weaving, such as shedding the warp threads, throwing the shuttle, and beating up the thread, are still retained. The frame of the power loom is of cast iron, and motion is com-

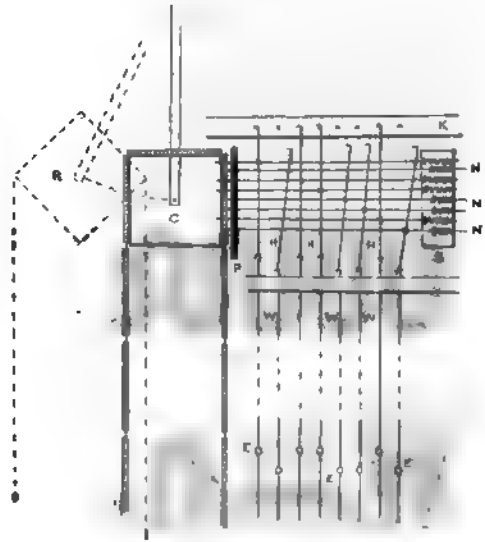

FIG. 13.—Diagram of Heddle-operating Mechanism of the Jacquard Loom. A, A, the chain of perforated cards; C, "cylinder" in normal position holding card against needle-plate P—the dotted lines show the position of C when swung outward and revolving; N, N, the needles as held by the spring-box S except when pushed back by the unperforated parts of the card; H, H, hooks actuated by needles; K, knife-beam for lifting the engaged hooks; W, W, wires to heddles, of which E, E, represent the eyelets each carrying a warp thread.

municated to the loom by means of a shaft, the stroke of the ley being made by cranks attached to the driving shaft, while the shuttle is thrown by means of a lever at the centre of the loom. Although the principle of the loom is the same in all kinds of weaving, yet there are numberless modifications for the production of special fabrics. The lappet loom may be employed for weaving either plain or gauze cloths, also for putting in representations of flowers, birds or the like, with the effect of embroidery.

**Cross Weaving** is a term applied to that process in which, as in gauze weaving, the warp-threads, instead of lying constantly parallel, cross over or twist around one another, thus forming a plexus or interlacing independent of that produced by the weft. It is a combination of knitting and weaving.

**Double Weaving** consists in weaving two webs simultaneously one above the other, using

two sets of warp threads from two warp beams, and interweaving the two at intervals so as to form a double cloth. Kidderminster or Scotch carpeting is the chief example of this process. Three-ply and four-ply cloths are similarly made. The plan of make-up of these fabrics is illustrated in Fig. 14.

FIG. 14.—Sectional Diagram of one of the many methods of weaving double cloth on two sets of warp.

**Pile Weaving** is the process by which fabrics like that of velvets, velveteens, corduroy and Brussels carpets are produced. In the weaving of these fabrics, besides the ordinary warp and weft, there is what is called the pile-warp, the threads of which are left standing in loops above the general surface until cut, and the cutting of which produces the pile. In such fabrics as Brussels carpet the loops are left uncut. The manner in which the pile-warp is woven into the fabrics is illustrated in Fig. 15. See **LOOM**; **VELVET**.

FIG. 15.—Sectional diagrams of two of the principal methods employed in the weaving of pile fabrics; showing both cut and uncut loops. W, W', wires on which the loops are formed.

RICHARD FERRIS.

**WEBB, Alexander Stewart**, American soldier and educator: b. New York, 15 Feb. 1835; d. 12 Feb. 1911. He was graduated from West Point in 1855, was assistant professor of mathematics there in 1857-61, and at the outbreak of the Civil War became major of the First Rhode Island infantry. He participated in the defense

of Fort Pickens, was at the first battle of Run, served in the Peninsular campaign; 1863 became brigadier-general of volunteers. At Gettysburg he assisted in repulsing Pickett's charge and received a Congressional medal in recognition of his gallantry. He engaged in the Rapidan and the Wildcat campaigns, was wounded at Spottsylvania upon his return to duty was appointed of-staff to General Meade. He received rank as major-general of volunteers in 1864 and was brevetted brigadier-general of regular army in 1869 and in 1870 at his own request received an honorable discharge. He was president of the College of the City of New York in 1869-1903 and wrote 'The Peninsula: McClellan's Campaign of 1862' (1862).

**WEBB, Aston**, English architect, b. London, 22 May 1849. He was educated in public schools, was articled to Banks and Partners, architects, and began practice in 1873. He was the architect for the completion of the Victoria and Albert Museum and the College of Science, South Kensington, and the Britannia Naval College, Dartmouth. He designed architectural accessories for the Victoria Memorial before Buckingham Palace. He designed many churches, commercial mansions, and, with F. I. Bell, the County Courts, Birmingham; the Birmingham University and the new schools of Christ's Hospital. He was president of the Architectural Association in 1884 and vice-president of the Institute of British Architects 1893-97. He was knighted in 1904 and given the K. C. S. in 1914.

**WEBB, Beatrice Potter**, English economist: b. England, 22 Jan. 1858. She was educated privately and later engaged in investigation of social conditions. In 1892 she married Sidney Webb (q.v.), with whom she has collaborated in the preparation of several works on economics. She served on the Royal Commission on Poor Law and its employment in 1905-09 and was joint author of the minority report. From 1909 she was honorary secretary of the National Committee for the Prevention of Destitution. She is prominent in the Fabian Society. She edited 'The Case for the Factory Acts' (1901), and is author of 'The Co-operative Movement in England' (1891; new ed., 1904).

**WEBB, Charles Henry** (a.k.a. PAUL), American journalist: b. Rouse's Point, N. Y., 24 Jan. 1836. He was born in New York City, 24 May 1905. He was on the staff of the New York Times (1860-63), and in 1863 he moved to California in 1863, where he founded the 'San Francisco Chronicle', which he edited till 1868. Subsequently he contributed to the New York Tribune humorous articles signed 'Jean Paul'. He invented an adding machine, but was known by his burlesque dramas, among which are 'Liffith Lank' (1867) and 'Saint Mo' (1868). Other works by him are 'Paul's Book' (1874); 'Parodies, Prose Verse' (1876); 'Vagrom Verse' (1899); 'Vagrom Verse' (1901).

**WEBB, James Watson**, American journalist and author: b. Claverack, N. Y., 8 Feb.

d. New York, 7 June 1884. He entered the United States army as second lieutenant and became adjutant in 1825; served in the West under General Scott, and resigned from the army in 1827. In that year he became editor of the *Morning Courier* in New York; this was united with the *Enquirer* as the *Courier and Enquirer*, which he edited until 1861, when it was merged in the *New York World*. At first he supported Jackson but later as vigorously opposed Jackson's measures, and made the *Courier and Enquirer* one of the leading Whig papers. In 1851 he was appointed engineer-in-chief of New York State and given the rank of major-general. After refusing an appointment as Minister to Turkey, he was appointed Minister to Brazil in 1861, which office he held until 1869. In 1865 when he was in France for a time, he negotiated a secret treaty with the emperor providing for the removal of the French troops from Mexico. He wrote 'Altowan, or Incidents of Life and Adventure in the Rocky Mountains' (1846); 'Slavery and its Tendencies' (1856), and 'National Currency' (1875).

**WEBB, Samuel Blatchley**, American soldier: b. Wethersfield, Conn., 15 Dec. 1753; d. Claverack, N. Y., 3 Dec. 1807. He joined the Revolutionary army immediately after the battle of Lexington, was engaged at Bunker Hill, became aide to General Putnam and in June 1776 was appointed private secretary and aide-de-camp to Washington, receiving rank as lieutenant-colonel. He was engaged at the battles of Long Island, White Plains, Trenton and Princeton, and in 1777 took command of the Third Connecticut regiment which he had organized, equipping it almost entirely from his own funds. He accompanied General Parsons' expedition to Long Island in 1777 and on 10 December was captured with his command. He remained a prisoner until 1780, when he was appointed to succeed Baron Steuben in command of the light infantry, with brevet rank of brigadier-general. He was one of the 16 founders of the Society of the Cincinnati in 1783, and in 1789 held the Bible, on which Washington took the oath as first President of the United States.

**WEBB, Sidney**, English political economist and Fabian socialist: b. London, 13 July 1859. He was educated in Switzerland and at the City of London College, and in 1878 entered the civil service, holding several different positions, chiefly in the colonial office, and resigning from the service in 1891. He was admitted to the bar in 1885. He was one of the founders of the Fabian Society (q.v.), and in 1891 was elected to the London County Council as a candidate endorsed by the Fabian Socialists. He is lecturer on political economy at the London School of Economics and Political Science and is a member of the Economic Faculty of London University. He has written 'Socialism in England' (1890); 'The Eight Hours' Day' (1891, with Harold Cox); 'The London Programme' (1892); 'Labor in the Longest Reign' (1897), and in collaboration with his wife, Beatrice Potter Webb, 'The History of Trade Unionism' (1894); 'Industrial Democracy' (1897); 'Problems of Modern Industry' (1898); 'English Local Government' (1906); 'English Poor Law Policy' (1910); 'The Prevention of Destitution' (1911), etc. 'The History

of Trade Unionism' is an exhaustive account of the origin and progress of the English labor unions; 'Industrial Democracy' shows the organization and ideals of the modern British trades unions. These two works form perhaps the most valuable contribution to the history of English labor, and written with sympathy and forcible directness, well express the power and vitality of the labor movement.

**WEBB, Thomas**, British soldier and Methodist pioneer in America: b. England, 1724; d. Bristol, England, 20 Dec. 1796. He was an officer of the Royal American army and saw service at Braddock's Defeat in 1755; at the storming of Louisburg, Nova Scotia, in 1758 and with Wolfe at the battle of the Heights of Abraham in 1759. He was converted to Methodism by the preaching of John Wesley at Bristol, England, and was afterward licensed to preach. He returned to America on military duty and after 1767 preached in New York in alternation with Philip Embury. He was the largest contributor to the fund for the erection of the John Street Church, New York. After his retirement from the army with rank of captain he devoted himself to the preaching of Methodism. He founded the first Methodist society at Philadelphia and also established societies in New Jersey, Delaware and Maryland, as well as holding services at his home in Jamaica, L. I. He twice revisited England to solicit funds and preachers for the Church in America. After the outbreak of the Revolution he returned to England and spent the remainder of his life as a preacher at Bristol.

**WEBB, William Henry**, American shipbuilder: b. New York, 19 June 1816; d. 30 Oct. 1890. He was educated in the grammar school of Columbia College, New York; learned the trade of shipbuilding in his father's yard; became manager of his father's business in 1843. Under Webb's management were built many ships of war for the United States and foreign governments, as the *General Admiral*, steam-frigate for Russia, two steam-frigates for Italy, the *Dunderberg*, iron-clad ram for the United States government. In 1890 were erected buildings at Fordham, N. Y., for an "academy and home for shipbuilders," founded by Webb. The objects of the academy and home are: 1. Relief of "aged, indigent and unfortunate men" who have been engaged in any department of shipbuilding in the United States; relief also of their widows. 2. Providing for American young men of good character gratuitous education in the profession of shipbuilding and machine-engine building, together with free maintenance.

**WEBB CITY, Mo.**, city in Jasper County, on the Kansas City Southern, the Saint Louis and San Francisco and the Missouri Pacific railroads, about eight miles east of Joplin, and known with its neighbor, Cartersville, as one of the "Twin Cities." It was first incorporated in 1876, three years after the discovery of extensive deposits of lead ore, zinc being discovered several years later, and in 1890 became a city, its government being administered by a mayor and a council of 10 members. It is important as a mining town, the Webb City-Cartersville mining district having very extensive deposits. It is the centre of a rich agri-

cultural and fruit-growing section. The Webb City Iron Works are the second largest in southwestern Missouri, and the city has also lumber and flour mills. It has 12 churches, five graded elementary schools and a high school. Webb City is the seat of the Great Western Normal School and Business College. The waterworks system cost originally \$100,000. It has two banks and two daily newspapers. Pop. 18,000.

**WEBB-KENYON LAW**, a regulation in regard to liquor traffic, declared constitutional by the United States Supreme Court 8 Jan. 1917. By this law, shipment of liquor from "wet" to "dry" States is prohibited. This decision also rendered constitutional the West Virginia law prohibiting the importation of intoxicants for personal use. By this means, a long controversy on the subject was ended and the enforcement of prohibition in dry States greatly enhanced.

**WEBB-PEPLOE, Hanmer William**, clergyman of the Church of England: b. 1 Oct. 1837 at Weobley. He was educated at Marlborough College, Cheltenham College and Pembroke College, Cambridge. In 1863 he was ordained deacon and priest; became curate of Weobley and served for four years. At the same time he was chaplain of Weobley Union until 1876, vicar of Kings Pym Cum Birley 1866-76 and of Saint Paul's, Onslow Square since 1876, prebendary of Saint Paul's Cathedral since 1893. In college he was a champion athlete and was seriously injured. As a result he was confined to his bed for three years and continued his college work on his back. He was Cambridge University preacher in 1896. Has been much interested in missions and connected with several missionary organizations. He is the author of 'I Follow After' (1894); 'All One: Sermons' (1896); 'Life of Privilege' (1896); 'Victorious Life' (1896); 'Calls to Holiness' (1900); 'Within and Without' (1900); 'Titles of Jehovah' (1901); 'Four Remarkable Letters of Saint Paul' (1903); 'He Cometh' (1905); 'Consider Him; or, Sketches of the Four Gospels' (1906); 'The Beautiful Name' (1910).

**WEBBER, wéb'ér, Charles Wilkins**, American author: b. Russellville, Ky., 29 May 1819; d. Nicaragua, 11 April 1856. In early youth he passed several years of adventurous life on the Texan frontier and later settled in New York where he was for a short time assistant editor of the *American Review* and a prolific contributor to that and the *Democratic Review* and other periodicals, in which appeared in a serial form his 'Old Hicks the Guide' and other tales of backwoods life and adventure. In 1849 he published the 'Gold Mines of the Gila.' His remaining works comprise the 'Hunter Naturalist' (1851); 'Spiritual Vampirism' (1853); 'Tales of the Southern Border' (1853), and 'Wild Scenes and Song Birds' (1854), forming a second volume of the 'Hunter Naturalist.' In 1856 he joined an expedition to Nicaragua in aid of William Walker (q.v.) and was killed in a skirmish.

**WEBBER, Herbert John**, American plant physiologist: b. Lawton, Mich., 27 Dec. 1865. He was graduated at the University of Nebraska in 1889 and took his Ph.D. at the Uni-

versity of Washington in 1901. He was in charge of the United States Department of Agriculture's plant-breeding investigations in 1889-1907, and investigated orange diseases in Florida in 1893-97. He served as professor of experimental plant biology at Cornell University in 1907-08; was acting director of plant breeding there in 1909-10, and was professor of plant breeding at the New York College of Agriculture in 1910-12. Since 1912 he has been director of the Citrus Experiment Station, dean of the Graduate School of Tropical Culture and professor of plant breeding at the University of California.

**WEBBER, Samuel**, American college president: b. Byfield, Mass., 1759; d. Cambridge, Mass., 17 July 1810. He was graduated at Harvard in 1784, subsequently entered the ministry, and in 1787 was appointed university tutor of mathematics. In 1789 he was appointed to the chair of mathematics and natural philosophy, which he retained until the death of President Joseph Willard in 1804, when he became his successor. He died while holding this office. He was one of the commissioners appointed to determine the boundary between the United States and the British provinces. He published 'A System of Mathematics' (1801).

**WEBER, väb'ér, Ernst Heinrich**, German physiologist: b. Wittenberg, Germany, 24 June 1795; d. Leipzig, Germany, 26 Jan. 1878. He was educated at Leipzig, was appointed professor of comparative anatomy there in 1818, and of physiology in 1840. He originated the formula known as Weber's Law (q.v.) and wrote 'Anatomia Comparativa Nervi Sympathici' (1817); 'Lehre vom Bau und von der Verrichtung der Geschlechtsorgane' (1846); 'Annotationes Anatomicae et Physiologicae' (1851), etc.

**WEBER, Georg**, German historian: b. Bergzabern, Rhenish Bavaria, 10 Feb. 1808; d. Heidelberg, 10 Aug. 1888. He was educated at Erlangen, traveled extensively, and was director of the normal school at Heidelberg in 1848-72. His writings, which include 'Lehrbuch der Weltgeschichte' (1847); 'Geschichte der Deutschen Litteratur' (1847); 'Allgemeine Weltgeschichte für die Gebildeten Stände' (15 vols., 1857-80), etc.

**WEBER, Karl Maria (Friedrich Ernst)**, BARON VON, German composer: b. Eutin, Grand Duchy of Oldenburg, 18 Dec. 1786; d. London, 5 June 1826. He was a pupil of J. P. Heuschkel of Hildburghausen, attaining great skill as a pianoforte virtuoso and much proficiency in the technique of composition; and continued his studies with Michael Haydn at Salzburg, and at Munich with Kalcher (harmony and composition) and Valesi (singing). His opera, 'Das Waldmädchen,' was produced with but moderate success at Freiberg, though more fortunate at Chemnitz and (in 1805) at Vienna. A second opera, 'Peter Schmolli und seine Nachbarn,' first presented at Augsburg (1803) met with no particular approval. Early in 1803 he went to Vienna, and there that curious genius the Abbé Vogler was for a year his instructor. By Vogler's aid, he secured the post of kapellmeister of the opera at Breslau (1804). He displayed great ability as an organizer and director, but resigned in 1806, and became musical

director to Prince Eugene of Württemberg at Karlsruhe, Silesia. In 1807 he entered the service of Duke Louis of Württemberg at Stuttgart as private secretary, and in 1808-10 was working on his first large opera, 'Silvana,' the libretto of which was to a large extent based on that of his earlier 'Waldmädchen.' He was falsely charged with fraud, and despite all lack of evidence against him, was perpetually banished from Württemberg 26 Feb 1810. Then he went to Mannheim, where his first symphony was most favorably received, and his piano-playing was also very successful; and thence to Darmstadt, where he once more became a pupil of Volger. His comic operetta, 'Abu Hassan,' was completed in 1810 and given at Munich, and 'Silvana,' with additions, gained adequate recognition at Berlin in 1812. It was not, however, until 1813 that Weber held an important appointment; in that year he was made kapellmeister of the Prague opera, and there proved himself the first of the Great German musicians to be conspicuous also as a conductor. His administration of marked success was brought to a close by his giving it up in 1816. His chief compositions of this period were settings of Körner's songs, and the cantata 'Kampf und Sieg,' founded on the battle of Waterloo. In 1816 he went to Dresden, where previously Italian opera had held undisputed sway, to organize the new venture of German opera; and soon he had attained, except among a few partisans, an unqualified victory. The appointment was confirmed for life, and he was frequently summoned to direct the music of the chapel royal. He became widely known with the presentation of his opera, 'Der Freischütz,' at Berlin, 18 June 1821, which was quickly echoed elsewhere, being simultaneously given in London in three different places. Few operatic works, it is said, have equaled it in immediate triumph. 'Euryanthe' did not meet similar approval at Vienna (1823), though appreciation was duly encountered in Dresden, Leipzig and Berlin. On the commission of Charles Kemble of Covent Garden, London, he wrote 'Oberon' to an English libretto by J. R. Planché, himself learning English to be able to work to better effect. He conducted the first 12 performances, and after a reception which almost surpassed that of the 'Freischütz,' played at numerous concerts. With the 'Freischütz,' which struck a distinctively national note, Weber became the founder of what is known as the romantic school of German opera. He has been claimed as a predecessor of Wagner in adapting his music to the dramatic requirements, and the use of leading motives. In his operatic works he apparently preferred legendary and supernatural elements, which he could make musically effective. Though his operas are the best known of his writings, he did musicianly and even brilliant work in the direction of Lieder and pianoforte compositions. Consult Jähns; 'C. M. von Weber: Eine Lebensskizze' (1873); the biographies by Rau (1865); Benedict (1881); Reissmann (1882); Gehrmann (1899), and his son Max Maria von Weber (Leipzig, new ed., 1912); also Benedict, 'Musiciens du Temps Passé' (1893), and the article by Spitta in Grove's 'Dictionary' (Vol. IV, 1889).

**WEBER, Wilhelm Eduard**, German physicist, brother of E. H. Weber (q.v.): b. Witten-

berg, 24 Oct. 1804; d. Göttingen, 23 June 1891. He was educated at Halle, was professor of physics at Göttingen in 1831-37 and occupied that chair at Leipzig in 1842-49, after which he resumed his chair at Göttingen. He was associated with his brothers and with Gauss in various publications concerning physics, and made valuable researches in the fields of electricity and magnetism. He also published a series of essays, 'Elektrodynamische Massbestimmungen' (1846-67). Consult Heinrich Weber, 'Wilhelm Weber' (1893).

**WEBER**, wē'bēr, a river of Utah, whose headwaters are on the west slope of the Uinta Mountains. It flows northwest through fertile lands and through a series of cañons; and after a course of nearly 200 miles it enters Great Salt Lake. The famous Weber Cañon is the gorge made by this river where it breaks through the Wasatch Mountains. The Union Pacific Railroad passes through this gorge. The descent in places is most rapid, and the consequent water-power is extensive. At Ogden, the mean volume of water is about 2,000 cubic feet a second. The Weber is much used for irrigation. The river has built up at Ogden a large delta which extends into ancient Lake Bonneville.

**WEBER'S LAW.** In the 30's of the last century E. H. Weber (q.v.) made the discovery that a subject who could barely distinguish between lifted weights of 29 and of 30 ounces could also barely distinguish between weights of 29 and 30 drachms. Similar results were obtained in the case of cutaneous pressure and in the visual measurement of short lines. That is, it appeared in each case that the just noticeable increment of a stimulus was not a constant, but bore instead a constant ratio to the strength of the stimulus itself. This generalization, which is Weber's law, is a precise statement of the fact which is familiar to us in such cases as that of the ticking of a watch, quite inaudible on the noisy street though it may be very loud in the silence of the bedroom. The ratio of the barely observable increment or difference lumen to the stimulus is dependent on the kind of stimulus used. For pressures on the tip of the finger it is nearly 0.05, for noise loudnesses it is about 0.33, for lifted weights, 0.033, and for brightness, 0.01. Weber's law is only an approximation at best. It is badly in error for very great or very small stimuli; even for those of moderate intensity it presupposes a complete adaptation of the perceptive organ. It is not in general valid for other attributes of sense than intensity, although it seems to hold good for visual extension. In the pitch of tones, for instance, the just noticeable increment is about .75 vibrations per second for a considerable range of the scale. In so far as we are able to equate easily noticeable intervals in different parts of an intensity scale, it appears that these obey the same law as just noticeable intervals; that equal-appearing intervals between stimuli are proportional to the intensity of the stimuli evoking the lower terms of the intervals, and are made up of an equal number of just noticeable intervals. This assemblage of facts was raised by G. T. Fechner (q.v.) to the dignity of a necessary law expressing the relationship of mind and matter. He represented the fact that a constant increment of a sensation is

produced by a fixed proportional change in the stimulus by the formula  $s_1 - s_2 = f\left(\frac{i_1}{i_2}\right)$ , where  $i_2$  is the stimulus inducing the sensation  $s_1$ . We obtain from this at once

$$s_1 - s_2 = f\left(e \log \frac{i_1}{i_2}\right) = f,$$

$$(e \log i_1 - \log i_2) = \phi, (\log i_1 - \log i_2).$$

As  $i_1$  depends only on  $s_1$ , and  $i_2$  depends only on  $s_2$  in the same way, we get  $s_1 = \phi, (\log i_1 - c)$ , and  $s_2 = k\phi (\log i_2 - c)$ , where  $c$  is the value of  $\log i_k$  for  $s_k = 0$ . Therefore  $\phi (\log i_1 - c) - \phi (\log i_2 - c) = \phi (\log i_1 - \log i_2)$ , so that  $\phi$  satisfies the functional equation  $\phi(x) - \phi(y) = \phi(x - y)$ .

Differentiating with respect to  $x$ ,  $\phi'(x) = \phi''(x - y)$ , which is only possible for all values of  $x$  and  $y$  if  $\phi'(x)$  is some constant such as  $K_1$ , or if  $\phi(x)$  is of the form  $K_1 x + K_2$ . It is easily seen that  $K_2 = 0$ . We thus get  $s_1 - s_2 = K_1 (\log i_1 - \log i_2)$ . By the proper choice of units this becomes  $s_1 = K \log i_1$ . Fechner's law is, then, that the sensation varies as the logarithm of the stimulus.

There are several serious objections to Fechner's treatment of the law. In the first place, it is more than probable that the basis of the phenomena observed lies rather in the make-up of the nervous system than in the transition from the physical phenomena of the nervous system to the percipient mind. Even Wundt's explanation of the facts by apperception is vitiated by the appearance of the same logarithmic formula in the reactions of the nervous system of a decerebrized frog. Secondly, what is being determined in the mind of the subject of an experiment on discrimination is not the difference between two mental states, but the *awareness* of that difference, which is altogether another thing. The existence of limina is in itself enough to refute Fechner's opinion that it is actually the difference between two mental states which is reported, for things identical with the same thing are identical with one another, whereas a weight of 61 drachms is sensibly equal to the discriminable weights of 60 and 62 drachms. In the third place, while measurement of sensations is a conceivable thing, it is most assuredly not done directly, so that the whole interpretation of Fechner's law remains indeterminate until a thorough logical analysis is made of the processes involved in our actual measurement of the intensity of sensation.

The general types of method used in experiments and investigations on Weber's law are that of just noticeable differences, where two stimuli are gradually separated or approximated until their difference appears or disappears; that of average error, in which the average error of the observer in selecting a variable stimulus equal to a given fixed stimulus is taken as the index of the just noticeable difference or limen; that of equivalents, which differs from that of average error only in that the stimuli are applied simultaneously to different parts of the body rather than successively to the same part; that of mean gradations, in which a supraliminal interval is bisected; and that of right and wrong cases, in which the mean position of the initial stimulus limen or the difference limen is determined by ascertaining throughout a series of trials for each intensity of stimulus or magnitude of stimulus difference the proportion of cases in

which its presence or absence is rightly judged. (See LIMINA; PSYCHOPHYSICS). Consult Delboeuf, J. R. L., 'Examen critique de la loi psychophysique' (Paris 1883); Fechner, G. **WEBSTER, Arthur Gordon**, American physicist; b. Brookline, Mass., 28 Nov. 1863. He was graduated at Harvard University in 1885, later studied at the universities of Paris and Stockholm, and in 1890 took his Ph.D., at the University of Berlin. He received in 1895 the Thompson prize, Paris, of 5,000 francs for experimental research on the period of electrical oscillation. He was assistant professor of physics at Harvard in 1892-1900; and from 1900 he was professor and director of physics at Clark University. He was appointed to the Naval Consulting Board in 1915; and to the National Research Council in 1917. He is an authority on sound and the inventor of several instruments of value in this connection. Author of 'A Mathematical Treatise on the Theory of Electricity and Magnetism' (1897); 'Dynamics of Particles of Rigid, Elastic and Fluid Bodies' (1903); 'Harrison Lectures on Sound, University of Pennsylvania' (1911), etc.

**WEBSTER, Daniel**, American statesman; b. Salisbury (now Franklin), N. H., 18 Jan. 1782; d. Marshfield, Mass., 24 Oct. 1852. He was the son of a New Hampshire judge and farmer and brother to a large family of boys and girls, all of whom worked and sacrificed in favor of Daniel whose health was apparently not robust. After rather meagre preparation he attended Exeter Academy a year. Thence he went to Dartmouth College where he was graduated in 1801 with good if not distinguished standing. He loved to study English and classical literature; he liked self-indulgence; and he was already an orator for Fourth of July occasions. More than once he had shown a disregard to that rigid honesty in little money matters which was later to become such a distressing trait of his character.

From Dartmouth to the farm of the hard-pressed father was not a congenial move for a young man so filled with ambition to play a rôle in the great world outside; but the road to the goal he vaguely set himself was not easy to find. He studied law a while in the office of a friendly lawyer nearby but inclined rather to general reading and to fishing than to rigid self-discipline. Next he turned to teaching school in the town of Fryeburg, Me., in the hope of winning ready money, so much needed in the Webster family, now that another son was sent to Dartmouth. After one session at Fryeburg, he returned to his native town of Salisbury and resumed the study of law in earnest. **Excerpt**

the brother who had been at Dartmouth, now took a school in Boston and Daniel followed him to the New England metropolis. Here he studied law under the distinguished Christopher Gore, a little later governor of Massachusetts, and always a prince of the old New England culture. Gore was certainly not of the type of Ezekiel Webster, the farmer judge of New Hampshire, but he was the bitter enemy of that "Mr. Jefferson, the atheist Virginian" who had broken the power forever of the Federalists of New England. Webster absorbed the politics of localism and provincial superiority which a little later threatened to ruin a great career.

Admitted to the Boston bar on the recommendation of Gore himself in March 1805, Webster, a little past his 23d birthday, returned to his native State and there, in the town of Boscawen, began the practice of his profession. He was quickly successful; but realizing that a larger sphere for the display of his talents was necessary, he removed to the important commercial town of Portsmouth in the year 1807.

Here he came into touch with real New England, with men who went "down to the sea in ships" and brought back rich harvests from the banks of Newfoundland, from the marts of Europe and even from the strange cities of China. He met and competed with great lawyers, like Jeremiah Mason and William Plumer, and he learned to think in generous figures, not in the niggardly shillings and pence of his boyhood. For five years he learned from these men and from renewed study of the great British law authorities. Webster received or gave himself a broad and deep training, whereas his great rival in life, Henry Clay, had little or no training. Moreover he earned large fees in those exasperating years of non-importation acts and embargoes, procured for himself a good town house and went back to his native countryside and married Miss Grace Fletcher, the daughter of the minister at Hopkinton. He spoke against the government on every suitable occasion; learned to write great orations and to move large audiences; and shaped barbed resolutions against James Madison and his inconsiderate Virginians who monopolized all the great offices of the nation. He learned rather better than history has recorded the language of resistance and secession. How could he do otherwise in a community whose people were delighted with young William Cullen Bryant's first poem, "The Embargo." Thus trained, deeply resentful at the policy of the national government in going to war with England a second time and ambitious to meet the enemy face to face, he became a candidate for a seat in the National House of Representatives, was elected on a most flattering vote and took his seat in May 1813.

From 1813 to 1817 Webster served New Hampshire in the House of Representatives. He opposed the Madison administration at every turn as every good New Englander must do. His protests against the conduct of the war, against Federal interference with New England trade and against the conscription of soldiers to fight the war were all animated by a warm and even impassioned sectionalism that reminded one of the Massachusetts secessionist, Josiah Quincy, just retired in disgust from a government which seemed destined to remain in the hands of slave-holding Southerners and igno-

rant frontiersmen. If Webster was more discreet, it was probably because the exasperation of Southern leadership was not quite so disturbing to him. But Webster was already a great lawyer and very much of his time, as well as the best of his talent, was during these four years spent in the Federal courts, both at Boston and in Washington where Chief Justice Marshall took pains to express his hearty admiration of a fellow partisan who could distress Mr. Madison. When the second term in the house was about to expire, Webster declined to offer himself in New Hampshire for re-election and removed to Boston, having first thought of making New York his home—for there, he said, the great decisions of the near future would be made.

In Boston, he quickly received that recognition and adulation which seems to have become necessary to his happiness and success. From 1816 to 1823, he again practised his profession with eminent success. His income from fees increased, in spite of the lean years that followed the close of the war with England, from \$2,000 to \$20,000 a year. The wealthy and the distinguished yielded to the son of the New Hampshire frontiersman who lived in the handsome house on Somerset street and deported himself with all the dignity of a Cabot or a Dana. With wealth abounding and social distinction undisputed, even in Boston, Webster now gave himself to the delivery of a series of commemorative orations that made his name known wherever New Englanders dwelt or New England newspapers were read. The Plymouth (1820) and the Bunker Hill (1826) addresses were the best of these, although others, like that on the Character of Washington and on the Landing at Plymouth, were reprinted in every important eastern paper. It was the day of oratory. There were few scholars and the clergy were fast losing their former mastery of the popular imagination. Public men must be learned, or appear to be so, and they must on occasion display their learning and their fine phrases in well-rounded periods. Of all Americans who essayed the rôle of classic oratory on the frontier soil of America Webster was the foremost. He had a remarkable personality; his voice and manner were both imposing and winning; and he had a memory that always served him admirably. When Webster spoke men laid down their tools or stopped their plows in the field and went to hear him. They would gladly stand in great outdoor audiences or crowd themselves into Faneuil Hall for hours at a time on hot days in order to look upon his majestic form or follow his moving imagery. Thus, before the great struggle in the country about the tariff and the powers of the Federal government, Webster was prepared as few men ever had been prepared for attack or defense.

It was an easy matter, then, in 1822 for him to procure once more a seat in the national House of Representatives. He represented Boston. He was a strict sectionalist. In 1814, when he spoke for a New Hampshire constituency, he had threatened to resist the national authority and he sympathized fully with those recalcitrant governors and judges of New England who refused to furnish troops to the national administration or who declared Federal laws inoperative in States that did not approve Federal policy. In 1820 Webster was so much

opposed to the tariff laws of the Union that he threatened secession in a notable speech. When he appeared in his place in the national legislature late in 1823 he was ready for a great struggle.

Henry Clay was the leader of the House of Representatives at that time and he was pressing with all his energies the tariff and internal improvement bills which together he christened the "American System." Webster opposed Clay in the best speech that had ever been made in Congress on the subject of the tariff. It is known as his free trade speech. It was delivered in 1824. The arguments which he then arranged and massed in consummate style have never been answered. But New England was changing. He was a New Englander. In 1825 a New Englander, John Quincy Adams, became President and half of New England changed its investments from shipping to manufactures. Before 1828 Webster was himself in a quandary. He must change his attitude or cease to play a part in public life. His position was exactly parallel to that of Calhoun who had been a strenuous protectionist but whose constituents now became free traders. Calhoun abandoned protection which South Carolina would no longer endure; and Webster abandoned free trade which Massachusetts then and henceforth condemned. Calhoun was the Vice-President and very ambitious to be President. Webster was elected to the Senate in 1827 and he too soon became possessed with the ambition to rise to the presidency.

When Webster took his seat in the Senate, Henry Clay was the Secretary of State and the director of the policy of the party with which Webster must work, the incipient Whig party, the party of protection to American industries, of wide-flung schemes of internal improvements and of expanding the powers of the national government. The New Englander quickly fell into line. In 1828 he made his first important speech in favor of the "American System," so ably condemned four years before, and Calhoun prepared to thwart that very tariff policy which he had done so much to set up in 1816. Nullification was about to be tried and Webster from opposing the national power, as he had done all his life, now prepared to champion that cause. The greatest speech of his life was delivered in February of 1830 when western influences in Congress opposed to the leadership of Henry Clay were being aligned with the southern influences and interests voiced by Calhoun and Robert Young Hayne. These leaders of the three great sections of the country were compelled to work out a national policy which it was hoped that a majority of the people might support.

Thomas H. Benton had pressed for six years his bill for a freer distribution of the public lands in the hope of building up the West at the expense of the East. Webster opposed the Benton plan. The Southerners were divided; but, after long and doubtful negotiations, they had made up their minds to support the western claims in exchange for support of their free trade policy. Jackson was made President upon this combination. Webster did not like the combination. It meant disaster for New England. But Jackson did not like the power and influence of Calhoun in the combination which lay behind his own presidency. When,

therefore, Calhoun prepared to launch a secession program, expecting that the West would remain quiescent, there were signs that the President would revolt. It was the interest of New England that Jackson should break, that the West should not continue their coalition,

Solomon Foot of Connecticut made a move in his resolutions of early 1830 in which it was proposed to withdraw lands from sale. Benton was quick to support the resolution as indicative of the provincial policy of New England. A great debate was begun. Hayne of Virginia made an elaborate attack upon the land, which roused Webster's ire; also publicly announced that the West would support the West in its land policy. He made a long and thoughtful argument on the growing powers of the Federal Government. The nation was only a confederacy; only what the Constitution provided power of original jurisdiction over Webster replied. He defended New England said nothing about the subject of lands; and closed in a magnificent appeal to the people of the country on behalf of the Union, one and inseparable, now. It was strange doctrine from New England. But New England had changed its attitude. Chief Justice Marshall's Federal courts had long been working the same end with New England and whole. Webster stirred in the West yet but half-aroused anywhere to a great national government. States, all sections and all. It was to be one of the class oratory. There can be no doubt to be a powerful influence during years. No President, duly meaning of his own office, could to an appeal like Webster's, known in April following that his New England opponent. His friends would have had him rights at a Jefferson dinner, nounced that he drank to the be preserved." If that were so South and West was dissolved Webster had done much to dissolve.

From 1830 to 1850 Webster remained uninterruptedly in the Senate. He the United States Bank in the upon the President and the nation in the great oration. He played the campaign of 1840 which election of William Henry Harrison idency and was under Secretary. When Vice-President Tyler May 1841 to the office made death of Harrison and when Henry took to manage Tyler as a modern ally manages a governor of his own Webster revolted against the chief, Clay, and retained his seat in Cabinet. As Secretary of State Webster negotiated a treaty with Minister, Lord Ashburton, which known by the names of the two

But Webster retired in May 1

**DANIEL WEBSTER**

nimation and election of Henry Clay to be foregone conclusions. Webster, of Clay's dislike of his insubordination, must support to the Clay ambition. Clay again defeated and Webster himself now found that his turn for the leadership of the party had come. He returned to the White House in 1845 where he renewed his opposition to the annexation of Texas in its final stages. The war with Mexico began while he was, as a full sympathy with the heated and able opposition of his section. But he was not much of a candidate for the presidency; his views very strongly. Yet he failed in his Whig nomination in 1848. A successful slave-holder, Zachary Taylor received the nomination as a result of Whig opposition to Webster and Clay. Taylor declared that it was an improper and unwelcome nomination; and both Webster and Clay declined to give public support. Yet Taylor was elected.

Calhoun, the slave-holder, urged the admission of California as a free State. As a civil war between the North and the South seemed imminent. Webster was still in the White House. Calhoun was again a member in Taylor's retirement that had been designed for him. Clay was returned to the Senate at a critical juncture to aid in reconciling the sections of the country, reconcile interests were in violent conflict. Since Webster and Clay so well represented the sections—the East, the South and the West—any agreement satisfactory to them would be satisfactory to the country. Webster took the lead, as he had done all his life. He placed himself in direct and bitter opposition to Taylor. The South would never consent to the admission of another free State south of the parallel of 36° 30', extended to the Pacific.

Webster expectedly President Taylor maintained the position that California must be admitted as a free State. A deadlock ensued. From the meeting of Congress in December 1849 until the 7th of March 1850 it seemed that a compromise of the Union must be the outcome. Under these circumstances Clay arranged his last great compromise. It was completed early in January. Private meetings of the Whigs and representatives were arranged. Parties sat down to dinners together and arrangements. Newspaper editors were consulted and resolutions made. When Clay at last made his appeal to Congress and the country, Webster's consent to follow him with a compromise appeal. But President Taylor would not do with the compromise. Webster and Clay had both said he was an unfit man for the office. Moreover the Southern leaders demanded Taylor, and a challenge of the President to his powers and his independence has invariably been fatal to the challenging President. Taylor would send the United States to any territory where the Southerners would recognize the authority of the United States. That meant immediate war.

Webster had been a nationalist since 1830. He was not in sympathy with the Administration of his own party, which was supported by the Whig Whigs. He was by nature a conservative who liked to have great social changes made slowly or not at all. He repre-

sented the manufacturers and the stable business element of New England and not what would be called the democracy of the North. He made the only decision that he could have made. It was given to the world on 7 March 1850 in a great and eloquent appeal to the public sentiment of the country, North and South, against the disruption of the Union. This decision of Webster broke the deadlock; it ranged his great followers alongside that of Clay. The country rallied to the two old chieftains. The President resisted till 9 July, when death removed him from the scene. Vice-President Fillmore, a friend of Webster and Clay, succeeded and the country breathed freely. In every large town there was a holiday, and big guns announced the passage of the compromise. It had been Webster's decision in March that produced the result. Not even Taylor's military stubbornness could long have withstood the tide of popular demand for a settlement.

Webster entered President Fillmore's Cabinet as Secretary of State and served the ideals of the country well, particularly in the publication of the Hulsemann letter, in which American sympathy for democratic uprisings everywhere was vigorously expressed. But he was denounced for his 7th of March speech most unmercifully. His name was anathematized in 'Ichabod,' one of the widely read poems of Whittier. But the country as a whole did not think less of him, only the people did not demand him for President. When the Whig national convention met in Baltimore, June 1852, to nominate a candidate for the presidency, Webster was the logical candidate. According to all the rules of regular political procedure, the great New England statesman should have received the nomination. But the convention, under the influence of Thurlow Weed and William H. Seward, preferred another military "hero." General Scott was nominated. Webster, broken hearted at the way the North had treated his 7th of March speech and deeply wounded by the conduct of the Whig leaders in Baltimore, went home to Northfield. There he made known his wish that his friends would vote for the Democratic candidate, Franklin Pierce. It was a trying ordeal, the public abandonment of his party. He died before the election. Like so many other great leaders, he died despairing of the republic.

WILLIAM E. DODD,  
Professor of American History, University of  
Chicago.

**WEBSTER, Ebenezer**, American patriot, father of Daniel Webster (q.v.): b. Kingston, N. H., 1739; d. Franklin, N. H., 1806. In his youth he served under General Amherst in the "old French war," and in 1761 was one of the original settlers of that part of the town of

Salisbury now known as Franklin. He united, as was common at the time, the occupations of farmer and innkeeper, took an active part in public matters, and at the outbreak of the Revolution led the Salisbury militia to Cambridge. Subsequently he fought at White Plains and Bennington, and served in other campaigns until the close of the war, when he had attained the rank of colonel of militia. He was at various times a member of both branches of the legislature, and in 1791 was appointed judge of the Court of Common Pleas, which office he held till his death. In personal appearance he resembled his son Daniel, being of large frame, with a swarthy complexion and dark piercing eyes.

**WEBSTER, Henry Kitchell**, American author: b. Evanston, Ill., 7 Sept. 1875. He was graduated from Hamilton College, Clinton, N. Y., in 1897, and in the following year was instructor in rhetoric at Union College. With Samuel Merwin, he has written 'The Short Line War' (1899); and 'Calumet "K"' (1901). His own work includes 'The Banker and the Bear' (1900); 'Rogers Drake, Captain of Industry' (1903); 'The Whispering Man' (1908); 'The Girl in the Other Seat' (1911), etc.

**WEBSTER, Herbert Tracy**, American eclectic physician and author: b. Portland Township, Chautauqua County, N. Y., 14 Oct. 1847. He was graduated at the Eclectic Medical Institute of Cincinnati in 1869, and in 1882 was appointed professor of materia medica in the California Medical College (now located at San Francisco), and now fills the chair of principles and practice of medicine in the same institution. He has written 'Principles of Medicine'; 'Dynamical Therapeutics' and 'The New Eclectic Practice of Medicine.'

**WEBSTER, Herman Armour**, American artist: b. New York, 6 April 1878. He was graduated at Yale University in 1900 and later studied art under Laurens in Paris. He subsequently lived chiefly abroad. He is known as a painter and is particularly prominent as an etcher. His usual subjects in this field are quaint scenes in out-of-the-way French towns. He has exhibited at the Paris Salon; the Royal Academy, London; the Western Society of Artists, Chicago; Rouen, France; and at the American Art Association, Paris. He is a member of the Royal Society of Painter-Etchers and of the Societ e Nationale des Beaux Arts, Paris. He was awarded a gold medal at the Panama Exposition in 1915. His work is represented in the Luxembourg, Paris; the South Kensington Museum, London; the Congressional Library, Washington; the Boston Museum; the Art Institute, Chicago; and in other important collections.

**WEBSTER, Jean**, American authoress: b. Fredonia, N. Y., 24 July 1876; d. New York City, 11 June 1916. She was educated at the Lady Jane Grey School in Binghamton, N. Y., and at Vassar College. After spending a few years in Italy and traveling around the world, Miss Webster returned to New York, and in 1915 married Glenn Ford McKinney, a New York lawyer. She was a grand-niece of Mark Twain. Her most popular production was the novel 'Daddy Long-Legs' which in its dramatic form was most successful. She wrote also

'When Patty Went to College' (1903); 'The Wheat Princess' (1905); 'Jerry Junior' (1907); 'The Four Pools Mystery' (1908); 'Much Ado About Peter' (1909); 'Just Patty' (1911); and 'Dear Enemy' (1913).

**WEBSTER, John**, English dramatist: b. about 1580; d. about 1625. He appears to have followed the occupation of his father, a tailor, and in 1604 was a freeman of the Merchant Taylors' Company. In 1602 he began to write plays in collaboration with other playwrights, but attained to his full power only when, between 1607 and 1612, he adopted independent authorship. He added to 'The Malcontent,' a play by John Marston, and was associated with Dekker in writing two vigorous prose comedies, 'Westward Hoe' (acted 1604) and 'Northward Hoe' (acted 1605). 'The White Devil,' or 'Vittoria Corombona,' a tragedy published in 1612, was his first independent work, and is now recognized as one of the best tragedies of its age. 'Appius and Virginia,' published in 1654, followed soon afterward and in 1616 his masterpiece, 'The Duchess of Malfi,' was first produced at the Blackfriars Theatre. It was first published in 1623. This great tragedy, which has won enthusiastic praise from Charles Lamb and many subsequent critics of eminence, is based on a Neapolitan story found in Bandello. 'The Devil's Law Case' was published in 1623 and appears to have been Webster's last play. Of other plays sometimes ascribed in part to Webster, only 'A Cure for a Cuckold' (published 1661) seems to contain any of his work. Webster wrote in 1624 a pageant for the Lord Mayor of London and in 1612 was associated with Heywood and Tournour in producing 'Three Elegies to the Memory of Prince Henry.' He also contributed verses to other works. There are editions of Webster's works by Dyce (1830; new eds., 1857 and 1886) and Hazlitt (1856). J. A. Symonds edited a selection in the 'Mermaid Series' in 1888 and there is an edition of 'The Duchess of Malfi, in the 'Temple Dramatists' by C. E. Vaughan (1896). Consult Hazlitt, 'Dramatic Literature of the Age of Elizabeth' (ed., 1840); Vopel, 'John Webster: Researches on his Life and Plays' (1887); Gosse, '17th Century Studies' (1883); Swinburne, 'Studies in Prose and Poetry' (1894). Lamb was the earliest among 19th century critics to give due praise to Webster and Swinburne enthusiastically places him next to Shakespeare among English dramatists.

**WEBSTER, Joseph Dana**, American soldier: b. Old Hampton, N. H., 25 Aug. 1811; d. 12 March 1876; son of Josiah W., minister at Hampton 1808-37. After graduation at Dartmouth in 1832, he studied law; became clerk in the war department, Washington, and was made United States civil engineer in 1835; was commissioned second lieutenant of topographical engineers in 1838; served in the Mexican War; resigned from the army, with rank of captain, 1854, to practice in Chicago as civil engineer. He perfected a system of sewerage for Chicago, the execution of which necessitated raising the grade of a large part of the city and involved many great and novel engineering feats. At the beginning of the Civil War he was charged with the construction of fortifications at Cairo, Ill., and Paducah, Ky.; became colonel of an Illinois artillery regiment

in 1862; as chief of General Grant's staff was present at Fort Henry and Fort Donelson; at Shiloh he was chief of artillery. He was commissioned brigadier-general 29 Nov. 1862, and served as military governor of Memphis and as military superintendent of railroads; he was again General Grant's chief of staff at Vicksburg, and held a like post under General Sherman from 1864 till the end of the war. Having been brevetted major-general of volunteers March 1865, he retired from the army and went back to Chicago; there he was assessor of internal revenue 1869-72, afterward assistant United States treasurer, and finally collector of revenue.

**WEBSTER, (Julia) Augusta Davies**, English poet and dramatist: b. Poole, Dorsetshire, 30 Jan. 1837; d. Kew, Surrey, 5 Sept. 1894. She was a daughter of Admiral George Davies and was married to Thomas Webster, a Fellow of Trinity College, in 1863. In 1879 she was elected to the London School Board. Her first work was published under a pseudonym, which she soon discarded, and her early inclinations led her to make translations from the Greek in which field she did admirable work. As a dramatic poet she takes high rank, but her verse appeals most nearly to highly cultured readers. Her works include 'Dramatic Studies' (1866); 'Portraits' (1870); the dramas 'Disguises' (1879); 'In a Day' (1882) and 'The Sentence' (1887); 'The Medea of Euripides,' translation (1868); 'A Housewife's Opinions' (1878); 'Daffodil and the Croaxaxicans' (1884), etc.

**WEBSTER, Noah**, American lexicographer: b. Hartford, Conn., 16 Oct. 1758; d. New Haven, Conn., 28 May 1843. In 1774 he entered Yale College but his studies were interrupted by the outbreak of the Revolutionary War, in which he served under his father as a volunteer. He was graduated in 1778 and was admitted to practise law in 1781, but the unsettled state of the country prevented his obtaining a suitable opening in his profession and in 1782 he removed to Goshen, N. Y., where he taught a classical school. Soon after he published his 'Grammatical Institute of the English Language,' in three parts, Part 1 (1783) containing 'A New and Accurate Standard of Pronunciation'; Part 2 (1784), 'A Plain and Comprehensive Grammar'; Part 3 (1785), 'An American Selection of Lessons in Reading and Speaking.' The first part of this work afterward became popularly known as 'Webster's Spelling-book.' In 1889 it was stated that 62,000,000 copies of the work had then been published. His literary activity was henceforth very great and among works issued by him during the next few years are 'Sketches of American Policy' (1784-85), an argument for the formation of a national constitution. In 1787, after the adjournment of the Constitutional Convention, he published the pamphlet, 'Examination of the Leading Principles of the Federal Constitution'; and 'Dissertations on the English Language' (1789). He began the practice of law at Hartford in 1789, but removed in 1793 to New York, where he established a daily paper, the *Minerva* (later *The Commercial Advertiser*), for the purpose of supporting the government. He published in 1794 a pamphlet on the 'Revolution in France' and wrote 10 essays under the

signature of 'Curtius' in favor of the Jay Treaty with Great Britain. These publications had a powerful influence in stemming the tide of feeling in favor of a French alliance. In connection with the visitation of yellow fever he made a special study of the history of pestilential diseases and wrote a work on contagious diseases which was published in England and America in 1799. In the previous year he had removed to New Haven. In 1802 he published 'Historical Notices of the Origin and State of Banking Institutions and Insurance Offices.' His great work was the 'American Dictionary of the English Language.' He devoted many years to the collection of new words and preparation of more free and exact definitions. In 1824, when the book was nearly finished, he visited Europe to procure such information as he had been unable to obtain in America. After a short stay in Paris he went to England, where he finished his dictionary during an eight months' residence in Cambridge. In June 1825, he returned to America. An edition of 2,500 copies of his dictionary was published in 1828, followed by an edition of 3,000 in England under the superintendence of E. H. Barker. The work contained 12,000 words and 40,000 definitions not to be found in any similar publication. In 1840-41 he published a second edition in two volumes, with extensive additions to the vocabulary and corrections of definitions.

Noah Webster properly takes rank as the greatest of lexicographers, his work being largely original and of vastly greater scope than that of earlier dictionary makers. He originated most of the accepted dictionary forms and laid the groundwork for the modern comprehensive lexicons. (See **DICTIONARY**). His 'Collection of Papers on Political, Literary and Moral Subjects' was a reprint of some of his earlier writings. Webster was throughout life associated with many of the most eminent men of the country and always took an active share in public life, supporting his party chiefly by his pen. Several enlarged and improved editions of his dictionary have been published since his death, both in America and in England, and it has always held its place as a standard work. Among his further writings are 'Letters to Dr. Priestly' (1800); 'Origin, History and the Connection of the Languages of Western Asia and of Europe' (1807); and a 'History of the United States' (rev. ed., 1838). Consult the 'Life' by Scudder (1882) in the 'American Men of Letters' series; and Ford's 'Notes on the Life of Noah Webster' (2 vols., New York 1912).

**WEBSTER, Pelatiah**, American political economist: b. Lebanon, Conn., 1725; d. Philadelphia, Pa., September 1795. He was graduated at Yale University in 1746, studied theology and in 1748-49 was engaged as a preacher. Afterward he entered upon a business career in Philadelphia and gained a considerable fortune. He was a lifelong student of the problems of currency, finance and national resources and during the Revolutionary War aided the cause with both his purse and his pen. He was imprisoned by the British at Philadelphia for more than four months in 1778 and had property to the value of £500 confiscated. Author of 'Essays on Free Trade and Finance' (1779-85); 'Dissertation Upon the Political Union and Con-

stitution of the Thirteen United States of North America' (1783); 'Essay on Credit'; 'Political Essays on the Nature and Operation of Money, Public Finances and Other Subjects' (1791), etc.

**WEBSTER, Sir Richard Everard, 1st Viscount Alverstone**, English jurist: b. 22 Dec. 1842; d. 1915. He was educated at Cambridge, was called to the bar in 1868, became queen's counsel in 1878 and was Attorney-General in Lord Salisbury's Cabinet in 1885-86, 1886-92 and 1895-1900. He was returned to Parliament for Launceston in 1885 and in 1885-1900 was member for the Isle of Wight. He was knighted in 1885, created a baronet in 1900 and in that year was raised to the peerage; in 1913 he was made a viscount. In 1893 he was one of the British representatives before the Bering Sea arbitration tribunal. He was Master of the Rolls, May-October 1900 and was then appointed chief justice. He served as a member of the Alaskan boundary tribunal in 1903. Shortly before his death he published 'Recollections of Bench and Bar.'

**WEBSTER, Mass.**, town in Worcester County, on the French River and on the New York, New Haven and Hartford and the Boston and Albany railroads, 15 miles south of Worcester. It is in an agricultural region and has considerable industrial interests connected with farm products. A lake (1,225 acres) is one of the attractions of the town. It has cotton and woolen mills, shoe factories and machine shops. It has a good water system. There are 11 churches, a high school, 13 graded public schools, three graded parish schools, a public library, two banks and two newspapers. The government is administered by annual town meetings. Webster was set off from Dudley and Oxford and in 1832 was incorporated. Pop. 12,565.

**WEBSTER-ASHBURTON TREATY**, The, in American history, a treaty between the United States and Great Britain, negotiated by Daniel Webster and Lord Alexander Baring Ashburton in August 1842. By this treaty the frontier line between the State of Maine and Canada was definitely agreed to. By this agreement seven-twelfths of the disputed ground, and the British settlement of Madawaska, were given to the United States, and only five-twelfths of the ground to Great Britain; but it secured a better military frontier to England, and included heights commanding the Saint Lawrence, which the award of the king of Holland, who had been chosen arbiter, had assigned to the Americans. By the 8th and 9th articles, provisions are made for putting an end to the African slave-trade; and the 10th article provides for the mutual extradition of suspected criminals. See **TREATIES**; **UNITED STATES—HISTORY OF ARBITRATION**.

**WEBSTER CITY, Iowa**, county-seat of Hamilton County, on the Boone River, and on the Webster City and Southern, the Chicago and Northwestern and the Illinois Central railroads, about 70 miles north of Des Moines. It is in an agricultural region, in which there are a number of coal mines. It has a shoe factory, foundry, machine shops, iron furnaces, flour mill, grain elevators and large coal yards.

Nearby are mineral springs of some importance. It has a high school, graded public and parish schools, four banks and a daily and four weekly newspapers. The city employs a business manager to operate its affairs. Pop. 5,834.

**WEBSTER GROVES, Mo.**, city in Saint Louis County, on the southwestern outskirts of Saint Louis, and on the Missouri Pacific and the Saint Louis and San Francisco railroads. It is chiefly a residential suburb of Saint Louis. The Loretto Academy, the Kendrick Seminary and a Masonic Home are located here. Pop. 7,060.

**WEBWORMS**, various species of caterpillars or lepidopterous larvæ, so named because of their habit of spinning webs of silk, enclosing leaves upon which they feed, and also serving as a shelter. As a rule neither the web-spinning nor the social habit is so highly developed as in the tent-caterpillars (q.v.), but there is no sharp distinction in the application of the two names. The species of caterpillars exhibiting such habits are quite numerous and belong to a number of genera and families of moths (q.v.). Some of them are of considerable economic importance. The fall webworm is the larva of the small white moth (*Hyphantria cunea*). As soon as they leave the egg all of the larvæ hatching from a mass spin a common web enclosing several leaves. After these are eaten the caterpillars wander farther and farther in search of food, sometimes destroying the entire foliage of a tree, but always returning to the shelter of the nest to rest when not feeding. The web may be extended to include whole branches. The caterpillars are covered with long hairs, and there are two broods, one in the spring and one in the fall, the latter being unusual among species of similar habit, wherefore the name. All kinds of shade and ornamental trees suffer from their attacks. Typical of a large and quite distinct group of caterpillars is the garden webworm (*Loxostege similalis*), which is a small, nearly naked caterpillar, that feeds in company on all kinds of garden vegetables, the leaves of which are drawn together in small webs. Some of the related species form large colonies, and one small form is often very destructive to dried clover hay. The root webworms are caterpillars of the little roll-wing moths. *Crambus ruficragellus* is a common species, which spins a web about the stalks and roots of grass to which, as well as to corn, it is sometimes very destructive. The true tent-caterpillars (q.v.) belong to the genus *Clisiocampa* and family *Bombycidae* or silk-spinning moths. A quite unrelated species is *Cacæria cerasivorana*, which forms veritable silken tents, sometimes covering small trees entirely. The general method of combating webworms is to destroy their eggs in winter, to burn the newly-formed tents and to spray the foliage about the tents with arsenical solutions. The ground-webs may be checked by fall plowing. Consult Harris and Flint, 'Insects Injurious to Vegetation' (New York 1884), and publications of the United States Department of Agriculture.

**WEDDERBURN, wéd'ér-bérn, Alexander, Baron Loughborough, 1st Earl of Rosslyn,**

British politician: b. Edinburgh, 13 Feb. 1733; d. near Windsor, England, 2 Jan. 1803. He was educated at the University of Edinburgh, was called to the English bar in 1757, entered Parliament in 1761 as member for Ayr and subsequently represented various constituencies. He pleaded the great Douglas case in 1768-89, and in 1771 left the ranks of the opposition to become a firm supporter of Lord North, who had appointed him solicitor-general. He strenuously opposed the claims of the American colonists, defending the policy of Lord North throughout the American war. He was made chief justice of the Court of Common Pleas in 1780, at the same time being raised to the peerage as Baron Loughborough, and in 1783 assisted in forming the coalition ministry, but in 1784 he joined the forces of Fox. He subsequently made friends with Pitt and gained from him the place of lord chancellor, after which he joined the supporters of George III. Upon his retirement from the chancellorship in 1801 he was created Earl of Rosslyn.

**WEDDERBURN, James**, Scottish psalmodist: b. Dundee, Scotland, about 1500; d. England, about 1564. He studied at the University of Saint Andrew, became interested in the Scottish Reformation and fled to France to escape prosecution as a heretic. He edited, with his brothers Robert and John, the principal song book used in Scotland, 'Ane Compendius Buik of Godly and Spirituall Sangs, Collectit Out of Sundrie Partes of the Scripture, wyth Sundrie of Uther Ballates Changed Out of Prophane Sangs, for Avoydng of Sinne and Harlotrie' (about 1548). Later editions of this work have been edited by David Laing (1868) and Mitchell (1897). He is also credited with the authorship of 'The Complaynt of Scotland' (1548), "the only classic work in old Scottish prose." Consult Mitchell, 'The Wedderburns and Their Work' (1898).

**WEDDING ANNIVERSARIES**, or celebrations, bear many familiar names from the sort of articles considered appropriate gifts on such occasions. They are as follows: Cotton wedding one year; paper wedding, two years; leather wedding, three years; wooden wedding, five years; woolen wedding, seven years; tin wedding, 10 years; silk and fine linen wedding, 12 years; crystal, (glass) wedding, 15 years; china wedding, 20 years; silver wedding, 25 years; golden wedding, 50 years; diamond wedding, 75 years.

**WEDDING CEREMONIES**. See **MARRIAGE, HISTORY OF**.

**WEDEKIND, Frank**, German dramatist and pamphleteer: b. Hanover, 24 July 1864; d. Munich, May 1918. He early became a journalist, but drifted for a time into the employ of Maggi's soups, for whom he conducted their advertising department (1886), traveled as a performer in Herzog's Circus (1888) and settled in Munich in 1890, where he spent the rest of his life in literary and artistic work of various kinds. Wedekind's plays, of which many may be obtained in English translations, are a savage exposure of the sexual hypocrisy of our times, which imposes upon all classes a degree of restraint and concealment of this fundamental passion inevitably resulting in the most dangerous repressions and perversions.

His first play treats this situation in a more pathetic and impressive manner than Wedekind has since succeeded in reaching in any of his more ambitious works, for he presents in it ('Frühlings Erwachen,' 1891, Spring's Awakening) the early sex interest of the child and the cowardice of parents in informing them on matters so vital to their future development. The terrible results of the misunderstood passion on the lives of the boys and girls in the play are perhaps more typical of Germany than of most other countries, owing to the more rigid course of German family life, but they are, in large measure, of universal application. Like several other plays of Wedekind, 'Frühlings Erwachen' has been played in New York, in English. 'Erdgeist,' also dealing with sex phenomena (1895), is more colossal in its scope almost crushing in the fury of its obsessions; its sequel 'Die Büchse der Pandora' (Pandora's Box, 1904) goes further in depicting the unsavory side of sex relations—Schnitzler's 'Reigen' is probably the extreme in the more aphrodisiac, more tempting direction—than any other play in literature. 'Erdgeist' and 'Die Büchse der Pandora' are more generally known under the collective title of 'Lulu,' the name of the man-consuming heroine. Other important plays are 'Die junge Welt' (1897), 'Der Liebestrank' (1899), 'Der Kammersänger' (played in New York in English, as 'The Tenor,' by the Washington Square Players, 1900), 'Hidalla' (1904), 'Die Zensur' (1906). The last named is a short but humorous dramatic attack on the censorship, with which Wedekind had come in contact because of outspoken utterances in a previous play. In fact, he once fled from Germany from persecution for *lèse majesté* (Majestätsbeleidigung), remained for a short time in Paris, returned voluntarily for trial, and served a short sentence in the fortress of Königstein (1900). After the outbreak of the European War in 1914, Wedekind seems, like many other German writers, to have been attracted to a more sympathetic view of German history and the German government, and wrote (1915) a rather over-patriotic historical play, 'Bismarck,' glorifying the events leading up to the foundation of the modern German Empire. He is one of the most vigorous and original satirists of our time; his ironic, cynical estimate and rejection of the universe is apparent behind all his ingenious puns, his grotesque humor, his eccentric caricatures, his burlesque distortions. As an artist he considers restrictions of form to be not binding, and produces not infrequently results that are refreshing or even childlessly grotesque. His works (7 vols.) appeared at Munich in 1913, and include short stories as well as plays. Biographical works on Wedekind have appeared from the pens of Pissin, Raimund (1905); Kapp, Julius (1909); and Elsner, Richard (1909).

JACOB WITTMER HARTMANN.

**WEDGE**, something made of hard substance in the form of a V or double inclined plane, for splitting or pushing apart by being thrust between two surfaces. It is often regarded as one of the mechanical powers, but is really an amplification of the inclined plane. The blade of an axe, the head of a chisel and the woodman's wedge are familiar illustrations

of common wedges. A very thin wedge driven with a comparatively light hammer may be made to exert a high degree of splitting force, owing to the mechanical advantage obtained. See MECHANICAL MOVEMENTS, POWERS AND APPLIANCES.

**WEDGWOOD**, wĕj'wüd, **Josiah**, English potter: b. Burslem, Staffordshire, 12 July 1730; d. Etruria, Staffordshire, 3 Jan. 1795. He was the son of a potter in the district and on the death of his father was employed in the pottery at nine. An incurable lameness later compelled him to give up the wheel and he removed for a time to Stoke, where he entered into partnership with other potters and where his talent for ornamental pottery was first displayed. In 1759 he returned to Burslem, and set up a small manufactory of his own, in which he made white stoneware, and developed the cream-colored ware for which he became so famous. He presently succeeded in producing a ware so hard and durable as to render works of art produced in it almost indestructible; and he also produced paintings on pottery without the artificial gloss so detrimental to the effect of superior work. In 1771 he erected potteries at Etruria, a village which he founded for his workmen. His improvements in pottery, which included form, substance and decoration, in all of which he attained an excellence rarely equaled, created the great trade of the Staffordshire potteries, which even during his lifetime acquired a remarkable expansion. He made 50 copies of the Portland vase, which were sold for 50 guineas each, a sum which it is said did not cover his expenditure in their production. (See POTTERY; WEDGWOOD WARE). Consult Jewett, 'The Wedgewoods' (1865); Meteyard, Eliza, 'Life' (1860); Rathbone, 'The Masterpieces of Old Wedgwood Ware' (1892-93); 'Life,' by Smiles (1894).

**WEDGWOOD PYROMETER**, in physics, a pyrometer in which temperature is ascertained by the contraction of baked clay, measured before and after its subjection to the action of heat.

**WEDGWOOD WARE**. England's most noted art potter was Josiah Wedgwood, born at Burslem, Staffordshire, in 1730. In 1754 he became Whieldon's partner, but started his Ivy House works in 1759, making "cream-color" ware. By 1773 Wedgwood's products were all being made at the newly-erected magnificent works called Etruria. "Jasper" ware (made first in 1775) was Wedgwood's most noted achievement. It was of colored body and decorated with Flaxman's reliefs in white. The texture of the paste was very beautiful and the ware was left unglazed (*biscuit*). It was used, not only in vases and table services, but also as cameos in medallions, plaques, brooches, shoe-buckles, carriages, snuff-boxes, etc. Jasper ground colors were dark and light blues, lavender, pink, two tones of green, black, so-called "lilac" and yellow — the rarest and most coveted of all pieces. First it consisted of a solid colored body of a most beautiful grain, but was later made in a white body and dipped to give a surface of color upon which the delicate white reliefs were laid. A few pieces (made since 1790) are "tricolored." The medallions (Hackwood, as well as Flaxman, did many of

the best) contained mythological and beautifully executed portraits of Franklin, Robert Boyle, Sir Isaac Priestly, Hamilton, etc. A fine ware named "pearl," was made from a Wedgwood's "Queen's ware" paste his cream-color patronized by Queen used on "shell" patterns and coated shell lustre enamel washes. Gold, low and silver (platinum) lustre made from 1792 to 1810 in tea-pots, cream jugs, candlesticks, tray black stoneware that Wedgwood called of Egypt" was used on "Etruscan" vases were then called) vase styles, panels, seals, plaques, busts, tea and etc., with reliefs of mythological subjects, horses, flowers. Noted are the ware of Zeno, Cicero, Plato, Chau Spencer, Bacon, Lord Chatham of sizes and the smaller Voltaire, etc. Most famous of Wedgwood's products glass Barberini or Portland vase (see VASE) in black-polished earthenware with applied white jasper base-relief of mottled bodies and glazes were in Burslem and Etruria, Wedgwood style through Whieldon's "tortoiseshell" etc, agate and other marbled ware variety was the "rosso antico" or u stoneware, after the Elers brothers on cream jugs, milk jugs, etc. The Greek "Etruscan" antique pieces were by a method Wedgwood termed painting; they used an enamel paste that produced a dull (*mat*) surface pieces copied were of the Greek period they are not much admired; is found in tea-cups, jugs, bowls, wood's "bronze encaustics" still called bronze (precipitated gold), and through jappanners' size is mostly Wedgwood produced scarcely any ware, but his nephew, Byerly (10 the great Josiah's death), made porcelain in small quantities, in imitation, mostly. Since 1872 porcelain produced again in Etruria. This glass has been continued under the designation Josiah to this day.

**Characteristics and Marks.**—The having the "Wedgwood" mark and "land" date from 1791, then the origin was added. "Old" Wedgwood been compared with a "baby's skin"; scribes it as "ivory, neither dry; looking on the one hand, nor of waxiness on the other; Yoxall says it "clay-pipe which has a film of soap-it." In Josiah's day the body had homogeneity and the workmanship ripples or stringiness" as appeared in are "Wedgwood & Bentley," "WE & BENTLEY," "WEDGWOOD & ETRURIA," in a circle; also "W. & were during the Bentley partnership "WEDGWOOD" alone was used. It always impressed. Much has been Wedgwood forgeries, but they are to be almost considered negligible. ware nor the impressed mark are easily imitate. Voyez, when dismissed by made cameos in Wedgwood style

a 'perfect master of the antique style,' few are known of. William Adams (worked under Josiah) made fine jasper cameos, but gave them the mark 'Adams' impressed. Garnier says a Herr Schmidt, at a Bayreuth factory (19th century), imitated Wedgwood's stoneware, using his mark.

**Bibliography.**—Burton, W., 'English Earthenware and Stoneware' (New York 1904); Church, A. H., 'Josiah Wedgwood, Master Potter' (London 1903); Jewitt, L., 'Life of Josiah Wedgwood' (London 1865); Meteyard, E., 'The Life of Josiah Wedgwood' (London 1865-66); id., 'Wedgwood and his Works' (London 1873); Rathbone, F., 'Old Wedgwood' (London 1893).

CLEMENT W. COUMBE,  
*Technical Art Expert.*

**WEDMORE, Frederick**, English author: b. Richmond Hill, Clifton, England, 9 July 1844. He was educated in France, has been art critic on the London *Standard* since 1878 and has published an edition of Michel's 'Rembrandt'; 'Poems of the Love and Pride of England' with his daughter Millicent. Among works of his own are 'Pastorals of France' (1877); 'Life of Balzac' (1890); 'Studies in English Art' (1876; 1890); 'On Books and Art' (1899); 'The Collapse of the Penitents,' a novel; 'Turner and Ruskin' (1900), etc.

**WEDNESBURY**, wenz'bū-ri, England, a manufacturing town in Staffordshire, 19 miles south-southeast of Stafford and 120 miles northwest of London. The Gothic parish church stands on the summit of a hill at the northern extremity of the town; there are several other churches and chapels, a town hall, free library, a mechanics' institute, public baths, a benevolent society, an almshouse and several schools. The principal manufactures are railway carriages, patent axles and general ironwork for railways; steel tubing for gas and water and steam pipes; gun locks and barrels, springs for coaches, hinges, nails, screws, spades, shovels, edge tools and wrought-iron work of every description. Pop. about 30,000.

**WEDNESDAY**, the fourth day of the week. The Germans call it *Mittwoch* (mid-week). The English name is derived from the old Scandinavian deity Odin or Woden. In Anglo-Saxon it is *Wodnesdag*; in Swedish, *Odensdag*; in Dutch, *Woensdag*. See also **ASH-WEDNESDAY**.

**WEED, Clarence Moore**, American naturalist: b. Toledo, Ohio, 1864. He was graduated from the Michigan Agricultural College in 1883 and is at present teacher of nature study at the Massachusetts State Normal School at Lowell. He has written 'Insects and Insecticides' (1893); 'Ten New England Blossoms and Their Insect Visitors' (1895); 'Seed Travelers' (1898); 'Insect World' (1899); 'The Flower Beautiful' (1903); 'The Nature Calendar Series' (1902-03); 'Bird Life Stories' (1904); 'Our Trees, How to Know Them' (1908); 'Wild Flower Families' (1908); 'Farm Friends and Farm Foes' (1910); 'Seeing Nature First' (1913).

**WEED, Edwin Gardner**, American Protestant Episcopal bishop: b. Savannah, Ga., 23 July 1837. He was educated at the University

of Georgia and studied theology at the General Theological Seminary whence he was graduated in 1870. He took priest's orders in the Episcopal Church in 1871 and was rector of the church of the Good Shepherd, Summerville, Ga., 1871-86. In the year last named he was consecrated bishop of Florida.

**WEED, Stephen Hinsdale**, American soldier: b. New York, 1834; d. near Gettysburg, Pa., 2 July 1863. He was graduated from West Point in 1854, served on the Texan frontier and in Florida wars of 1855-57, receiving rank as lieutenant in 1856, and in 1858-61 he was on duty in Kansas and Utah. In 1861 he was promoted captain and assigned to the command of a battery in the Army of the Potomac. He was engaged in the Maryland, Peninsular and Northern Virginia campaigns and fought at Manassas, Antietam and Chancellorsville, receiving promotion to brigadier-general of volunteers for gallantry at the latter. He commanded a brigade of artillery at Gettysburg 2 July 1862 and was killed while holding Little Round Top against the terrific onslaught of the Confederates. The place where he fell is now called "Weed's Hill."

**WEED, Thurlow**, American journalist and political leader: b. Cairo, Greene County, N. Y., 15 Nov. 1797; d. New York, 22 Nov. 1882. He entered a printing office at 14, but left his trade for a time to serve in the army during the War of 1812; in 1815-19 he worked as a printer in New York, and in 1819 went to central New York State, where he established and edited successively *The Agriculturist* at Norwich, and the Onondaga County *Republican* at Manlius. In 1822 he became editor of the Rochester *Telegraph*, a daily paper, and later its proprietor. During the Anti-Masonic excitement he stopped the publication of the *Telegraph* and issued the *Anti-Masonic Enquirer*. He was twice elected to the State legislature on the Anti-Masonic ticket, and while in Albany became noted as a shrewd political manager. In 1830 he moved to Albany and established the *Albany Evening Journal*, which he edited till 1865. This paper was first used as a means of attacking the Albany "Regency," a body of politicians under the leadership of Martin Van Buren, and it soon became the leading journal of the Whig party in the State. Through the influence of this paper and his political skill, Weed became the dominant State manager of the Whig, and later of the Republican, party. He held no public office himself, but for many years practically controlled the nominations for State officers; his control being used as a rule for the public good; some of the most efficient governors of the State were elected under his management. He also took a leading part in national politics as early as 1824, and when J. Q. Adams was nominated for the Presidency was instrumental in uniting the Clay and Adams factions; was particularly influential in securing the nomination of Harrison in 1840, Clay in 1844 and Taylor in 1848, and materially aided in the nomination of Scott in 1852 and Frémont in 1856. In 1860 his first choice for the Presidency was Seward, but he loyally supported Lincoln after his nomination and urged his renomination in 1864. Weed had long been a personal friend of Seward and was for some time closely

associated with Seward and Greeley in what was known as "the political firm of Seward, Weed and Greeley." In 1861 he went to Europe on a diplomatic mission to place the North in a favorable light before foreign governments and to prevent their intervention in behalf of the South. After 1865 he was for a time a member of the editorial staff of the *New York Times*; in 1867-68 was editor of the *Commercial Advertiser* in New York. His health then forced him to resign continuous journalistic work, but he continued to write occasionally for newspapers and periodicals, and though he took no active part in politics, his advice was sought by Republican leaders and had no small influence in shaping the policy of the party. He published 'Letters from Europe and the West Indies' (1866), and prepared his 'Autobiography,' which was published after his death (1884). Consult Barnes, 'Memoir of Thurlow Weed' (1884); Alexander, 'Political History of New York' (New York 1906).

**WEED, Walter Harvey**, American geologist: b. Saint Louis, Mo., 1 May 1862. He was graduated as mining engineer from Columbia University, School of Mines (1883) and appointed assistant geologist, United States Geological Survey in that year. In 1883-89 he was engaged in Yellowstone Park investigating hot springs and geysers, and glacial and sedimentary formation. To him is due the discovery that the brilliant coloring about hot springs and geysers are not mineral but due to living algae; and he also found and described Death Gulch. He also made the discovery that Death Gulch gave out carbon dioxide gas from an extinct hot spring, and it was this that killed wild animals that strayed there. He was occupied in general geologic exploration work in Montana, 1889-98. His most notable contribution to science was the theory of secondary enrichment of mineral deposits published in 1899, now generally accepted. This was followed by the theory of enrichment by ascending alkaline waters. He was one of the first to describe contact metamorphic ore deposits, and to interpret replacement deposits correctly. He is a member of practically all important scientific societies and was appointed special expert and commissioner on copper for Louisiana purchase exposition, 1904. In 1906 he resigned from United States Geological Survey to become chief geologist and examining engineer for General Development Company, and in 1910 went into private practice as consulting engineer and mine valuer. In recent years he has been expert witness in many important mining lawsuits. His publications include 'Copper Mines of the World'; 'Nature of Mineral Deposits' (a textbook, a revision and translation of Beck's German treatise); 'Geology of Butte, Montana'; 'Geysers'; 'Secondary Enrichment'; and many papers of the United States Geological Survey and in 'Transactions' of the American Institute Mining Engineers, and the technical journals.

**WEEDEN, William Babcock**, American manufacturer and economic and historical writer: b. Bristol, R. I., 1 Sept. 1834; d. 1912. He studied at Brown University, and then engaged in the manufacture of woolen goods in Providence. In 1861 he joined the Union army

as first lieutenant of artillery; was promoted captain after the first battle of Bull Run; was present during the siege of Yorktown, and took part in the engagements at Hanover Court House, Mechanicsville, Gaines' Mill and Malvern Hill. In August 1862 he resigned and resumed business in Providence. His publications include 'Mortality of Prohibitory Liquor Laws' (1875); 'Social Law of Labor' (1882); 'Economic and Social History of New England, 1620-1789' (1890); 'War Government' (1906); 'Early Rhode Island' (1911).

**WEEDS** are plants growing where they are not desired. There are no plants which are weeds, *per se*, since in nature each plant has its place, and since in cultivated areas any plant, useless or useful, may become a weed. Thus grass would be considered a weed in a bed of garlic, and vice-versa. Many plants, however, are popularly dubbed weeds because they are troublesome in fields and gardens, but even among these are not a few which are cultivated; for instance, purslane, lamb's quarters and sorrel. Far from being the useless and obnoxious things that they have long been reputed to be, weeds have performed a distinct service, which they still continue, in agriculture; they have compelled the husbandman to practise clean cultivation, upon which the success of his crops very largely depends.

Weeds often must be eradicated upon land that has become foul under neglect. Upon pastures and lawns that commence to fail the two principal ways of management are to make more grass grow or to plow the land and grow some other crop upon it for a year or more. The former is usually more feasible with lawns; the latter with meadows and pastures. Often a reseeding to grass will be sufficient. The plantain, dandelion and similar weeds troublesome in lawns may be cut out individually, but to keep them out the growth of grass must be encouraged by sowing extra seed and by fertilizing. In land that has lain fallow the annual weeds may be destroyed by frequent cultivation; biennial and perennial weeds, by short rotations of crops, especially such as include intertillage crops, like potatoes, beans and turnips. The one necessity to observe in combating perennial weeds is to prevent their forming leaves and thus elaborating food. In low grounds where sedges, rushes and bracken often abound, the land may be rid of these weeds by draining. In gardens many weeds may be "smothered" by growing leafy crops which will shade the ground. Ground which is kept free from weeds in the early months may become choked with weeds toward autumn and these may reseed the ground for the following year. Mowing before the plants blossom, or plowing the ground are often practised. In some cases, however, the plants may be allowed to remain as a cover crop to prevent the washing of the soil during winter. This practice is most common in orchards. A cover crop sown by the orchardist is preferable.

Besides the usual means of seed dispersal, such as wind and water, weeds are frequently distributed by means of haled hay, manure, and imperfectly cleaned seeds of the crops sown. This last is particularly prevalent with such difficulty cleaned seeds as grass and clover. Hence the advisability of purchasing only the

best seeds. It is not remarkable that many of the most troublesome weeds are imported from foreign countries, because being removed from their natural controls they find less resistance and spread accordingly.

Weeds are often of service in aiding the farmer to judge the needs of his land, since many kinds grow only where the conditions are peculiarly adapted to them. The character of their growth also indicates the quality of the soil. Wild carrot and the ox-eye daisy grow only upon poor soils, or soils that have been robbed of their fertility. Sheep sorrel indicates acid land and the necessity of applying lime to "sweeten" the soil. Bracken, sedge and moss show that the land needs drainage. Dark green foliage and large size of plant and leaf are good indications of abundant nitrogenous plant food in the soil; and yellowish foliage and sparse, stringy growth shows lack of this material.

**WEEHAWKEN**, wē-hā'kēn, N. J., town in Hudson County, on the Hudson River, and on the New York, Ontario and Western and the West Shore railroads, opposite New York. It is one of the largest coal depots in the United States. It has the coal docks and freight sheds of the Erie Railroad Company and the coal docks of the Delaware and Hudson Canal Company and the Pennsylvania Company. It has several manufacturing establishments. Two of the Hackensack Water Company reservoirs are located here. Weehawken is known as the dueling place of Alexander Hamilton and Aaron Burr. The post office of Weehawken is in the town of Union adjoining. Pop. 13,000.

**WEEK**, a period of seven days, one of the common divisions of time. The week is an arbitrary division of time, and the question when, why and by whom it was first adopted necessarily arises in connection with its actual prevalence. One explanation is that the number seven occurs so conspicuously in mythical and occult lore. It was also early used as an indefinite unit, and things were counted by sevens, where later they were enumerated by dozens or hundreds. Another natural explanation offered is that it has been adopted as a quarter lunation; but as there is no absolute necessity for dividing the month into four, and a large fraction is needed to make the weekly square with the lunar periods, this explanation is not satisfactory. The week is, in fact, a much closer division of a year than of a month; but the division of the year into 52 portions is so purely arbitrary that this can hardly suggest the origin of the week. The convenience of some short recurring period or cycle of days is obvious, and it is the prevalence alone, and not the occurrence of a particular cycle, that has to be accounted for. The practice of antiquity on the subject does not seem to have been so uniform as is sometimes supposed. Among the nations who adopted the week as a division of time, the Chinese, Hindus, Egyptians, Chaldeans, Jews, Persians and Peruvians have been mentioned, but in some cases the antiquity of the practice is doubtful, and in others the name has been applied to other cycles than that of seven days. The nations with whom the weekly cycle has been traced with certainty to the greatest antiquity are the Egyptians and the Hebrews. With the former we only know of its existence, but with the latter it had a much

more important character. Their earliest records speak of its existence, and refer it to a period previous to that of the nation itself. Laban, the uncle of Jacob, alludes to the week as an established measure of time in Gen. xxix, 27. The origin of the week is further ascribed in the Jewish Scriptures to the creation of the world, and is wrought into the institutions of the nation in a variety of ways, but particularly by the consecration of the seventh day to the worship of the Creator. The Hebrew word for week is of a general signification, and applies equally to a period of seven days, seven months, and seven years, each of which had a particular celebration attached to it in the Hebrew ritual, hence the use of days to represent years in the prophetic writings is according to the natural genius of the language. The number seven had a mystic significance attached to it in the symbolism of the Jewish religion in a variety of other ways. The Romans and Greeks each divided the month into three periods (see *CAL-NDAR*), and were not acquainted with the week till a late period. The Romans, however, had for civil uses, as the arrangement of market-days, a cycle of eight days, the ninth day being the recurring one, instead of the eighth, as with us. The use of the week was introduced into the Roman Empire about the first or second century of the Christian era from Egypt, and had been recognized independently of Christianity before the Emperor Constantine confirmed it by enjoining the observance of the Christian Sabbath. The names given by the Romans to the days of the week, and which have pervaded Europe, were derived from the planetary system, which was supposed to consist of the sun, moon and five planets, Mars, Mercury, Jupiter, Venus and Saturn. With the Mohammedans the week has also a religious character, Friday being observed by them as a Sabbath. The Chinese week is said to consist of five days, named after the five elements, iron, wood, water, feathers and earth. See articles on the different days of the week.

**WEEKES**, wēks, Henry, English sculptor: b. Canterbury, 1807; d. 29 May 1877. He was for many years the principal assistant of the sculptor Chantrey, was elected to the Academy in 1863 and became professor of sculpture there in 1873. Besides the earliest bust of Queen Victoria (1837) he executed statues of Latimer, Cranmer, Bacon, Charles II and others.

**WEEKS**, Edwin Lord, American artist: b. Boston, 1849; d. Paris, 17 Nov. 1903. He was a pupil of the Beaux-Arts (Paris), of Gérôme, and Bonnat, and sketched and painted in Cairo, Jerusalem, Damascus, Tangier and other parts of the Orient, obtaining there material for the genre-scenes from Eastern life with which he won his reputation. A frequent exhibitor at the Salon, he obtained honorable mention there in 1885. Among the other distinctions which he received were the diploma of honor at the Berlin international exhibition in 1891, and a special medal and prize in 1896 at the empire of India exhibition (London). Specimens of his work are in the Pennsylvania Academy of Fine Arts, Philadelphia, the galleries of Greater New York, and the Corcoran Gallery of Washington. Among his paintings are 'Cup of Coffee in the Desert'; 'Jerusalem

from the Bethany Road'; 'Pilgrimage to the Jordan'; 'Scene in Tangier'; 'Arab Story-Teller' (exhibited at the Centennial Exhibition, Philadelphia, 1876); 'Departure for the Hunt — India'; 'Moorish Camel-Driver.' He also wrote 'From the Black Sea Through Persia and India' (1895), and 'Episodes of Mountaineering' (1897).

**WEEKS, John Wingate**, American legislator: b. Lancaster, N. H., 11 April 1860. He was reared on a farm and in 1881 was graduated at the United States Naval Academy and in 1881-83 served as midshipman in the United States navy. In 1886-88 Mr. Weeks was assistant land commissioner of the Florida Southern Railroad and from 1888 to 1912 was member of Hornblower and Weeks, bankers and brokers, of Boston. He was alderman 1900-02, and mayor in 1903-04 of Newton, Mass., was chairman of the Republican State convention in 1905 and a member of Congress from 1905 to 1913 from the 12th Massachusetts district. He was a member of the United States Senate from 1913 to 1919; received 105 votes for the Presidential nomination in the Republican National convention, Chicago, in 1916 and in 1898 commanded a division of the Massachusetts Naval Brigade with rank of captain. In 1918 Mr. Weeks was defeated for re-election to the Senate.

**WEEKS, Raymond**, American philologist and phonetician: b. Tabor, Iowa, 2 Jan. 1863. He was graduated at Harvard University in 1890 and later studied at the universities of Paris and Berlin, taking his Ph.D. at Harvard in 1897. He was professor of the Romance languages at the University of Missouri in 1895-1908; held that chair at the University of Illinois in 1908-09, and at Columbia University since 1909. He was in the ambulance service in France in 1917-18. In 1910 he was one of the founders of the *Romanic Review*. He was an assistant editor of the 'New Standard Dictionary' (1913); and is general editor of the Oxford French Series. He was joint author of 'The N. E. A. Phonetic Alphabet' (1912); has contributed verse and short fiction to the magazines; and is author of 'Origin of the Covenant Vivien' (1902); 'La Chivalerie Vivien' (1909), etc.

**WEEKS, Feast of** (Heb. *Shabuoth*), the second of the great Hebraic religious festival. It is thus called from the fact that it forms the culmination of the seven weeks succeeding the Passover feast. Primarily it appears to have been connected with the celebration of the end of the harvest, but later also with the giving of the Law on the 50th day after the departure from Egypt. In the New Testament it is called Pentecost (q.v.), the Greek word ( *πεντηκοστή* ) signifying 50th (from *ἡμέρα*, day).

**WEEMS, wēms, Mason Locke**, American Protestant Episcopal clergyman: b. Maryland, about 1760; d. Beaufort, S. C., 23 May 1825. He began the study of medicine, but gave it up and went to London, where he was educated for the clerical profession, but found no bishop in England to admit him to holy orders. There was then no Anglican bishop in America, and the professional plans of Weems were obstructed by peculiar difficulties. (For an account of them consult McMaster's 'History of the People of the United States,' Vol. I). Returning to this

country, he preached at different places, apparently never having a regular charge, although it has been said that the rectorship of Mount Vernon parish (there was no such parish) was held by him before the Revolution, as claimed by himself; also that he officiated in the old Pohick Church, of which Washington was an attendant, which indeed he may have done, but not until long after Washington's attendance there had ceased. About 1790 he became a book agent for Mathew Carey (q.v.), and traveled through the South selling works, some of which were his own. He made himself popular by exercising his talents for comedy and his skill with the violin, probably diverting and (through his sermons) exhorting the people by turns. A book of his own writing which he offered for sale was 'The Drunkard's Looking Glass' (6th ed., 1818). His 'Life of Washington,' by which he is best known, first appeared in 1800, and during the 19th century the number of its editions exceeded 70. The traditional conception of Washington rests mainly upon this work, as do the story of the cherry-tree and other anecdotes which historians reject, most of which first appeared in the 5th edition (1806). His other publications, all more or less tawdry and inaccurate, include 'Life of General Francis Marion' (1805); 'The Philanthropist' (10th ed., 1809); 'God's Revenge Against Gambling' (3d ed., 1816); 'Life of Benjamin Franklin, with Essays' (1817); 'Life of William Penn' (1819); 'Hymen's Recruiting Sergeant' (7th ed., 1821 and 'The Bad Wife's Looking Glass' (2d ed., 1823).

**WEENDIGO**, wind-ēgō (meaning "cannibal") mythical tribe of Indians believed in by the Algonquin and other eastern races. The Chippewa and the Ottawa thought they inhabited an island in Hudson Bay; while certain other tribes placed them indefinitely in the far north country. Indian stories tell of a terrible Weendigo with two faces and monstrous ears, who could see and hear everything. The "great weendigo" was a monster so huge that his step shook the earth. So terrible was his gaze that no one looked upon him and continued to live. For this reason no one could accurately describe him. He lived far within the forest; but for the same reason, no one knew exactly where. Like the forest Indians, he was much of a wanderer, and consequently was found, now in one place, now in another. For this reason he was the more to be feared, as one was liable to come upon him suddenly when least expected. But though no one had lived to describe him, there were many who had heard his tramp as it shook the forest and his terrible voice as he roared in rage. Sometimes the Great Weendigo makes himself small and induces the unwary warrior or hunter to follow him; but he who does so never returns. He is much taller than the tallest wigwam ever built, and his ears stick out like those of a mountain cat. These he uses for hunting bags; and in them he stores, for the time being, all he does not care to eat. The Great Weendigo is supposed to be especially fond of children and to keep a supply of them constantly in his great ears. Sometimes children thus imprisoned have escaped from the Weendigo, when the proper magic has been brought to bear upon the giant. A customary way of frightening Algonquin children into being good was to tell them the Weendigo would

catch them and put them in his ears, or roast them and eat them. Numerous mythical folktales have grown up about the Weendigo, many of which are imaginative and dramatic. The Great Weendigo had the power of self-transformation; and he frequently changed his form to gain his ends. The Weendigo was firmly believed in from the Hudson Bay to the head of Lake Superior and throughout all the Algonquin country from this line eastward.

**WEENIX, Jan, yān vā'niks, THE YOUNGER,** Dutch painter, son of Jan Baptist: b. Amsterdam, 1644; d. there, 20 Sept. 1719. He painted landscapes, animals, flowers and fruit, but excelled in the representation of dead game and hunting scenes. His pictures of this class are unrivaled by any productions of the Dutch schools, and command large prices. He finished with extreme neatness, and exhibited a clear and brilliant coloring and a wonderful knowledge of chiaroscuro.

**WEENIX, Jan Baptist,** Dutch painter: b. Amsterdam, 1621; d. Ter May, near Utrecht, 1660. He was instructed by Abraham Bloemart and Nicolas Mojer, and at 22 visited Rome, where he acquired a reputation by his Italian seaports and landscapes with architectural accessories. The last 12 years of his life were passed in Holland. He was a rapid painter, having been known to finish three half-length portraits with accessories in a single day, and excelled in history, portrait, animal, landscape and marine painting, being on the whole most distinguished in the last-named department.

**WEeping CROSS,** a cross of stone or wood, erected at the side of a road, at which penitents prayed and wept for their sins. Hence the old English saying, "To return by weeping cross," that is, to return in sorrow from some message or undertaking. These crosses were removed in England when that country became Protestant, and the saying is now obsolete.

**WEEVER** (variant of weaver, or of the obs. *wiever*, from Lat. *viperā*, viper), a fish of the genus *Trachinus*, two species of which are recognized: *T. viperā*, five to six inches in length, and *T. draco*, 10 to 12 inches. They possess sharp opercular and dorsal spines, with which they can inflict a painful wound. The sting is believed not to be poisonous, but it is very similar to that of the sting-ray (q.v.). The name weever is hence applied to any of the *Trachinidæ*.

**WEEVIL,** a general name applied not only to various genera of adult beetles but also to their larvæ. They form a group *Rhynchophora*, or snout-beetles, so called from the characteristic production of the head in the form of a prominent snout, bearing the elbowed antennæ at the sides and the small mouth at its tip. There are several families, but most of these beetles belong to the *Curculionidæ*, which is said to include upward of 600 genera and 20,000 species. All of them are vegetarians and the larvæ are little white or yellow, fat footless grubs which mostly live within the tissues of plants, and are especially destructive to nuts, seeds and fruits. One of the most conspicuous and harmful is cotton-boll weevil (*Anthonomus grandis*). It is about one-fifth of an inch long and may be differentiated from related species by the fact that the tibæ of the first

pair of legs are provided with two small spines. Immediately after transforming from the pupal state the color is reddish but some time after emergence the color becomes considerable darker. The grub-like larvæ are considerably longer than the adults, strongly curved, white with pale yellowish heads. The eggs are deposited in punctures made by means of the beak of the female weevil in the buds (called squares) and bolls. The larvæ devour the interior. Infested squares practically invariably fall to the ground but bolls always remain attached to the plant. In the case of the squares, of course, the fruit is ruined. In case of bolls only the infested like or apartment is destroyed. The life-cycle is completed in about 20 days and there is an inextricable confusion of generations. The winter is passed in the adult stage, the individuals flying to the woods or seeking shelter in débris around or inside of the cotton fields.

This insect probably originated in Central America. It was introduced into the United States near Brownsville, Tex., about 1892. By 1895 it became established as a serious pest and has continued to spread northward and eastward. It has now extended about 585 miles northward from Brownsville and to a point within 10 miles of the Mississippi River in Louisiana. Five counties in southwestern Arkansas have also become invaded. Efforts to stay the progress of the weevil have been unavailing, but an effective method of mitigating its damage has been perfected. The methods of destroying or controlling recommended by the Department of Agriculture, which has published several valuable pamphlets on the natural history and injurious work of this insect, are the removal of the plants from the fields in the fall when there is no prospect of any more fruit being allowed to mature; early planting, the use of early maturing varieties, the application of fertilizers and intensive cultivation.

The grain-weevil (*Sitophilus granarius*) is a little dark red beetle about an eighth of an inch long. The eggs are deposited on wheat after it is stored, and the larvæ burrow therein, each larva inhabiting a single grain. The rice-weevil (*S. oryzae*) destroys rice and Indian-corn in a like fashion; this species has four red spots on the elytra or wing-covers. Another species (*Calandra palmarum*) infests palm-trees, is common in Guiana and attains a length of two inches, the larvæ burrowing in the pith of the trees. *C. sacchari* inhabits sugar-canes. The genus *Rhynchites*, of which the grape-weevil (*R. bacchus*) is an example, has the head broad behind; it devastates the growing vines, and strips them of their leaves. The plum curculio (*Conotrachelus nenuphor*) causes great damage to plums, cherries and other stone fruits. The eggs are laid one at a place in the young, forming fruit, upon the flesh of which the larva feeds, causing it to drop prematurely or to become "wormy." The beetle is less than one-fifth of an inch long and dark brown spotted with black and yellow. The familiar chestnut-worm is the larva of *Balaninus rectus*, remarkable for the great length of the snout, which exceeds the short robust body and which is adapted for piercing the thick burrs of the

young chestnuts, permitting the deposition of an egg in the kernel. Related species of the genus infest other nuts. Equally troublesome to fruit-growers are the species of *Anthonomus*, of which one pretty little weevil (*A. signatus*) causes great damage to the Sharpless and other staminate varieties of strawberry. This species attacks the flowers, and the larvæ feed upon the pollen. Quite different in its habits is the potato weevil or potato-stalk borer (*Trichobaris trinotata*), the larva of which bores passages in the stems of potatoes and wild plants of the same family. The clover-weevil (*Phytonomus punctatus*) has green larvæ, which differ from all of the foregoing in living exposed to the air and light, though they feed chiefly at night. They eat the leaves, and as they hibernate in the ground and begin to feed almost as soon as the clover sprouts in the spring they become most serious pests. The adults are nearly a third of an inch long, thick-bodied and short-snouted, with strongly knobbed antennæ.

To the family *Bruchidæ* belong the extremely destructive pea and bean weevils, which have the proboscis short and curved down on the breast and the antennæ not elbowed. They are small beetles with stout bodies and the swollen abdomen often projecting beyond the tips of the wing-covers. Unlike the *Curculionidæ*, which become quiescent and assume an appearance of death, these beetles are extremely active and fly when disturbed. The larva of the pea-weevil (*Bruchus pisi*) damages peas, the eggs being laid when the peas are ripening. They destroy much of the substance of the grain, lessen its germinating power and pupate in its interior. The mature insect is black marked with white spots, and about an eighth of an inch long. The *B. pisi* was at one time so destructive in North America that its ravages threatened to wholly exterminate the pea crops. Several species are named corn-weevils, from their destructive effects in granaries. *B. granarius* also attacks peas, and one species infests the cocoanut. The bean-weevil (*B. fabæ*) is plain brown in color but otherwise similar.

Weevils are very difficult to control on account of their small size, inconspicuousness and the fact that the destructive larvæ are generally beyond the effective reach of insecticides. The best measures consist in the total destruction by burning of all infested fruits, nuts or stems, the digging or plowing in the late fall of the ground in which the pupæ hibernate, and in the case of the pea and bean weevils the fumigation with carbon bisulphide of all infested seed. Consult Harris and Flint, 'Insects Injurious to Vegetation' (New York 1884); Saunders, 'Insects Injurious to Fruits' (Philadelphia 1883); Smith, 'Economic Entomology' (Philadelphia 1896); and special papers published numerously by the United States Department of Agriculture and by the experiment stations of various States.

**WEEYOT.** See WISHOSKAN.

**WEIDNER**, wid'nér, Revere Franklin, American Lutheran theologian: b. Centre Valley, Pa., 22 Nov. 1851; d. Tangerine, Fla., 5 Jan. 1915. He was graduated from Muhlenberg College, Allentown, Pa., in 1869, from the Lu-

theran Theological Seminary, Philadel: 1873, and after being ordained to the was pastor at Phillipsburg, N. J., 1873 at Philadelphia 1878-82. He was prof English, history and logic at Muhler 1875-77, and in 1882-91 was prof dogmatics and exegesis at Augustan: logical Seminary, Rock Island, Ill. In named year he accepted the presidency chair of dogmatic theology at the Ch: theran Theological Seminary. He: 'Commentary on the Gospel of Mark: 'Biblical Theology of the Old Te: (1886); 'Annotations on the General: (1897); 'Theologia; or the Doctrine: (1903); 'Studies in Exodus' (1903), e

 weighed, the ratio of the weight  
 e to that of the adopted unit is  
 Such machines may be conven-  
 d in three general classes—  
 balances, "unequal armed" bal-  
 spring" balances.

ned balances are represented by  
 forms of "scale-beams," in which  
 s hang below the beam, and the  
 s" in which the scale-pans are  
 am, both forms operating by ad-  
 equilibrium between a known and  
 weight. Unequal armed balances

ed by those consisting of a single  
 those formed by combinations of  
 d levers and steelyards, such as  
 es and weighbridges, in which a  
 weight at one end of a beam  
 es a heavy unknown weight at the  
 pring balances operate on the prin-  
 ten a helix is subjected to a ten-  
 sion of elongation increases pro-  
 the increase in the force of  
 he simplest form, it consists of a

of hard steel of a high elastic  
 nmonly used it is suspended from  
 by a hook at its upper end, while  
 d is bent into a hook, which is  
 nother hook to which the article  
 d is attached. An index attached  
 and moving along the face of a  
 te indicates the amount of ten-  
 s of the adopted unit of weight.

nce is so arranged that the axis  
 is always a plumb line, under  
 rest, and is capable of weighing  
 int within the elastic limit of the  
 capacity of such balances is gen-  
 and they are extensively used  
 for other purposes where a high  
 uracy such as may be obtained by

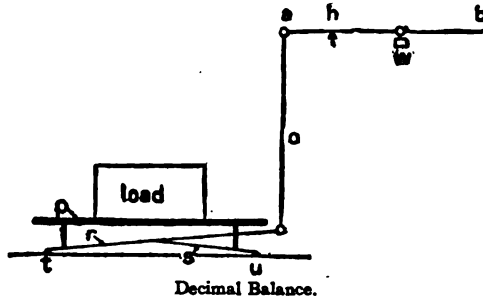

s is not required. On the other  
 ous forms of dynamometers em-  
 gistering the pull of locomotives  
 th enormous capacities. In this  
 e "torsion balance" may be con-  
 tioned, although in reality it is a  
 rally used for the purpose of  
 izontal forces, rather than weights  
 stood. In its simplest form it com-

m, supported by a wire stretched  
 which passes through its centre  
 When twisted by the application of  
 ie beam, the elasticity of the wire  
 played by the weight of the beam  
 y balance. For measuring hori-  
 ons caused by electric, magnetic,  
 rees, the wire is stretched verti-

rms of weighing machines of the  
 ype with small capacities, such as

counter-scales, chemical and assay balances, etc.,  
 see BALANCE.

The majority of the machines of large ca-  
 pacity known as "platform-scales," used for  
 weighing heavy loads such as carts loaded with  
 grain, hay, coal, building materials, etc., oper-  
 ate on the principle of the lever, and belong to  
 the class designated as unequal-armed balances.  
 They are sometimes arranged as "decimal bal-  
 ances," the ratio between the small known  
 weight on the weighing beam and the unknown  
 weight on the platform or bridge being indi-  
 cated in multiples of 10. Such a balance con-  
 sists of a lever (ab), suspended at (h), and  
 connected by the rod (o), with two levers (r)  
 and (s), hinged at (t) and (u), respectively.  
 A platform (p), resting by means of standards  
 upon the levers (r) and (s), accommodates  
 the load which is counterbalanced on the long  
 arm of the weighing beam or lever (ab), by a  
 sliding weight—(w). When a load is placed  
 upon the platform (p), the levers (r) and

(s), are depressed, and exert a downward pull  
 on the short arm of the weighing beam through  
 the rod (o), with a consequent lifting of the  
 long arm. This pull is counterbalanced by  
 sliding the weight (w) along the long arm  
 until it is brought into a horizontal position.  
 The weighing beam being graduated with an  
 adopted unit of weight and fractions thereof  
 (usually pounds), the weight of the load on the  
 platform is ascertained by a simple direct read-  
 ing of the graduated scale. In the smaller  
 scales, the weight (w) equals one pound, and  
 counterbalances a load of 100 pounds upon the  
 platform, but it is evident, that by varying the  
 number of levers and the relative lengths of  
 their arms, any desired ratio between the load  
 and the counter weight may be readily obtained.  
 In scales used for weighing loaded wagons and  
 cars, the ratio varies from one to 500, or one  
 to 1,000. Cattle scales are capable of weighing  
 from 10 to 200 head of cattle at a single opera-  
 tion, and the capacity of grain scales ranges  
 upward of 500 bushels, while the large iron  
 and steel manufacturing plants and gun shops  
 employ machines with capacities exceeding 100,-  
 000 pounds. The machine at Watervliet Ar-  
 senal, Watervliet, N. Y., used for weighing  
 guns, has a capacity of 300,000 pounds.

With the advent of the automobile and its  
 far greater capacity of burden the platform-  
 scales formerly used to weigh loads drawn by  
 horses have become obsolete, and with the re-  
 building of such weighing machines automatic  
 recording devices have been added, so that a  
 modern scales of this class will weigh a load  
 of coal approximating five tons within the

limit of error of three ounces, and print the correct weight upon a tape without the services of any attendant.

Self-discharging scales are also much in use for measuring units of weight; as for instance the filling of packages of commodities, as coffee, sugar, flour, cereals, etc. The same idea is embodied in receiving scales in large establishments, where coal, feed-water, sand, cement, ore, crushed stone, etc., are weighed as delivered, the receiving hopper discharging when the weight equals one ton, 100 pounds, or any other desired amount.

Railroad or track-scales are of prodigious size and capacity. The largest of this type in the world is a "suspended-platform" scales in the West Albany yard of the New York Central Railroad. The weighing rail is 90 feet long, and the capacity is 825 tons.

A new idea in heavy-work scale construction is known as the flexure-plate scale. In this type thin plate fulcrums of chrome-vanadium-steel take the place of the usual knife-edge pivots. They operate by bending instead of frictional movement on bearings. They have been found of most dependable accuracy and unequalled endurance, being unaffected by dampness or changes of temperature, and thus entirely free from the variations common to the ordinary track-scales.

The conveyor scale weighs material as it passes on a conveyor belt making use of electricity instead of weights for the recording. The belt is so arranged in reference to the weighing apparatus that the full belt is weighed against the empty return belt. A vertical plunger in a tube partly filled with mercury rises and falls in the tube according to the weight of material passing. The moving mercury brings more contact points into action the greater the thrust of the plunger, and the varying current makes its record automatically on a traveling tape. A standard comparison of amperes per hour and tons per hour gives the figure by which the weight is readily computed.

The computing scale is a machine which carries an attachment for indicating a certain limited range of prices. Usually it carries a cylinder covered with a paper roll ruled in many different proportions, each ruling indicative of a certain price unit. The cylinder turns with the weight, thus showing the cost at several different prices per pound.

The difficulty of exactitude in weighing is recognized and a legal "tolerance," as it is called, is permitted, within which no one can be accused of dishonesty or fraud. These tolerances are as follows: On counterpoise scales, one grain on one-fourth ounce; two grains on one ounce; 10 grains on 10 ounces; 10 grains on one pound; 40 grains on 10 pounds; 100 grains on 50 pounds. On platform scales one ounce is allowed on 50 pounds; one pound on 800 pounds; two pounds on one ton. On railroad or track-scales the permissible error is four pounds per ton.

**WEIGHT THERMOMETER.** See THERMOMETER.

**WEIGHTS AND MEASURES.** Weights and measures are fundamental necessities of commerce, industry and science. Measurement is required in the exploration of lands and waterways, in their location and transfer, in the

work of construction of buildings, bridges, railroads and other engineering works, in the manufacture of foods, in the preparation of compounds and in the purchase, shaping and sale of materials. Weights and measures are essential to all barter of goods. Here, the accuracy may range from the "heap" or "pile" of ancient times to the one one-hundredth of a cent used in cotton and spelter quotations "on change," estimates of value which we call prices being based on a specified weight of gold. Weights and measures are essential in all construction whether the precision be the "rule of thumb," or the millionth of an inch in optical work, or the one-ten-thousandth of an inch in the manufacture of fine machinery. The pharmacist with his weights compounds the prescriptions which mean health and life to the sick. In the extractive and compounding industries, weights and measures are used to determine the essential proportions in analyses and compounds, and precision is the main condition of reproducibility of results. Likewise the manufacturer must accurately weigh, measure and test his materials to secure perfect construction. Surveying and navigation would be very primitive were it not for the rigorous measurements of base lines, accurate triangulation, precise leveling, including even such delicate measurements as the variation of latitude. Weights and measurements will in fact be found necessary in the discovery and in the statement of industrial and scientific facts of all kinds. The birth of the exact sciences was coincident with the development and application of quantitative measurements to the phenomena of nature, and the rapid growth of modern science has since been parallel with that of precision. James Watt was one of the earliest to suggest international standards which would enable scientific results when published in terms of such standards to be intelligible and reproducible the world over. Precise and uniform standards made possible the interchangeability of parts in machinery, first practically applied by Eli Whitney and to-day one of the most important principles in manufacturing.

**Classification.**—Weights and measures ordinarily include those defining length, area, volume, capacity and weight. These are relatively the most important measures used by man. However, within the last half century when such products as power, electric current, heat, light, refrigeration and services or other kinds have entered the world's markets as commodities for manufacture, purchase and sale—the scope of weights and measures has widened to include units used in the measurement of velocity, pressure, energy, electricity, temperature and illumination. Technical requirements also resulted in a series of compound units such as the knot, a unit of speed for vessels of one minute of the earth's circumference per hour; the ton-mile used in transportation rates and statistics; the foot-pound, a unit of energy; the dyne, the international unit of force and other units of the centimetre-gram-second system of scientific units in use throughout the world. Such compound units are multiplying apace with the technical needs, and have proven of inestimable value and economy by the facility and precision which they afford in conveying exact quantitative results of experiment and observation. With advancing needs the units of weight

and measure have extended to microscopic and to telescopic dimensions. The millimicron of the physicist and the still smaller Angstrom unit of which it requires 254,000,500 to make one inch, are used in spectrum analysis for measuring the dimensions of light waves, while on the other hand the "earth's orbit" (meaning the mean radius of the orbit) is used by astronomers in measuring stellar distances. In addition, the "light-year" is used for the greatest distances, this unit being the distance which light traverses in one year, or about 6,000,000,000,000 miles. With the extension and division in size of units, the kinds of instruments utilized and methods of application of the units themselves have multiplied. Almost every occupation has its particular units, its methods of making measurements and its special measuring instruments. A few of the thousands of the latter may be cited, such as the common desk rulers, carpenter's folding rules, draughtsman's scales, surveyor's chains, engineer's tapes and level rods, lumberman's log rules and board measures, the merchant's yard stick, the tailor's tape, the shoe, glove and hat-measures, machinist's scales, measuring bars, micrometers, micrometer calipers, limit gauges of ring and plug types, end and line standards of precision. In measuring volume we have the standard capacity measures, milk measures, beer measures, wooden dry measures, a vast variety of standard flasks, glass graduates such as burettes, pipettes and other volumetric apparatus of the druggist, physicist and chemist, the gauging rods for casks and cargoes, gasometers reading in cubic feet, tanks and reservoirs with graduated scales reading volumes directly. For weighing, we have even-balance scales, steel-yards, platform scales, spring balances, all ranging from the most delicate analytical balances to the master scales for weighing canal boats and railway trains. Scales are especially designed for every particular need, and the countless varieties attest the high state of the art of weighing and its great importance in industrial and scientific work. Such instruments have multiplied in form and number and the demand for them has grown so rapidly that the manufacture of weights, measures and measuring instruments forms in itself a whole group of industries.

With the development of units of measure of the order of inter-molecular distances on the one hand and of almost interstellar distances on the other, and the multiplication of kinds of instruments used in measurement has come the invention of a large variety of measuring appliances which automatically indicate the result upon a scale. Of this class are thermometers, spring balances, aneroid barometers, pressure gauges, speedometers and indicating meters of all kinds. Computing scales not only indicate the weight but show the computed total price of the article at several prices per pound. Many of this class of instruments also make continuous record of the measurements showing by a curve the values at successive moments of time. Of this type are the automatic recording instruments used to record temperature, air pressure, sunshine, rainfall, electrical quantities as well as tide recorders, anemometers and many others. Equally interesting are those measuring instruments like dividing engines, trip scales or trip measures which besides meas-

uring definite lengths, weights or quantities automatically perform certain operations, such as graduating a scale, delivering or tipping a certain weight of grain, or delivering certain volumes of liquids. Closely related are those devices which integrate quantities delivered or magnitudes measured, such as the small map wheels which measure distances on maps, or the planimeters which measure areas within irregular contours, and all forms of gas and water meters, integrating rain gauges, integrating watt meters for measuring electric power consumed. These instruments usually indicate on a dial the total number of units measured since the last zero setting.

**Metrology.**—Many sciences and industries have given the science of metrology their best thought and labors. Chemistry opened up new chapters in the science of the refractory metals, developing iridium and platinum of purity requisite for the world's fundamental standards of mass and length, producing in conjunction with metallurgy the remarkable nickel-steel alloy "invar" (q.v.), having practically a zero temperature coefficient of expansion; the alloy manganin free from temperature coefficient for electrical resistance; Jena glass, a material for measuring flasks and thermometer bulbs which practically eliminates temperature disturbances. To optics and the glass industry we are indebted for the microscopes, telescopes, polariscopes and other optical instruments which form essential parts of modern measuring apparatus. Optical methods based upon the interference of light waves have made possible the detection of changes of dimension far beyond the power of the microscope to detect. By such methods plane glass surfaces are produced having errors of less than a millionth of an inch, and in the interferometer is provided the most delicate and sensitive length-measuring instrument known to man. Metallurgy and engineering have developed methods of fusing, casting and tempering materials to be used in measuring apparatus, and have developed the accurate machining of such instruments. Astronomy has given the precision measurements of time, the "second" being the unit of time in the international C. G. S. system of units. Mathematics has devoted a large section of its science to the theory of observations and added rigor in their adjustment, and in the elimination of accidental errors, and by developing the theoretical side of precision measurements has rendered the greatest service to metrology.

**Unit Standards.**—The standards of length and mass are fundamental. From these and the unit of time practically all other standards are derived, either directly or indirectly. The derived standards include those used in the measurement of volume, density, capacity, velocity, pressure, energy, electricity, temperature, illumination and the like. The production of copies, multiples and subdivisions of the fundamental standards, the construction of the derived standards, and the comparison of the standards used in scientific work, manufacturing and commerce with the fundamental or derived standards of the government are functions of the Bureau of Standards in the United States and of similar bureaus in other countries. In the United States the standard of the weights and measures of trade is maintained through the State, county and city sealers

of weights and measures with an efficiency dependent upon local administration. For more precise purposes, however, uniformity and precision are attained and maintained only by regular reference of the local standards to the fundamental standards of the government, at the Bureau of Standards in Washington.

The units of weight and measure in the United States are practically those used in the colonies prior to the formation of our government. While Congress has never definitely authorized the weights and measures in common use, it has sanctioned their use by its act of 14 June 1836, providing that accurate copies of the yard, pound, etc., be furnished as standards to each State of the Union. The constitutional power "to fix the standard of weights and measures," vested in Congress (1. 3, ¶ 5, United States Constitution) has rarely been exercised, so that legislation on weights and measures has been confined to the individual States, and in this manner numerous differences in usage have grown up in the several States, although the same general system of weights and measures prevails throughout the country. The customary units of length are defined by reference to the yard. The yard itself was formerly defined as the length of a certain brass bar, the standard yard, kept at the Office of Standard Weights and Measures in Washington. Since 1893 the yard is defined in terms of the international metre. The yard appears to have been a unit of length in England since very early times. The name signified in Old English and in Anglo-Saxon (*gyrd*) a rod or stick. A standard bronze yard of 1496 still exists in England, having been used for the verification of other yards until 1588, when a new standard was made which is also in existence to-day. This yard, known as the Winchester standard, was the legal standard in England until 1824, when new standards, the imperial standards, were authorized.

When the Coast Survey was organized it was found necessary to have a definite standard of length, and an 82-inch bar was secured from the instrument maker, Troughton, of London. This bar was nearly a copy of Troughton's scale, and had not been compared with the British standard yard, but the distance between the 27th and 63d inch marks on the bar was taken as representing the standard yard, and was made the basis of the standards sent out in accordance with the act of Congress of 1836. In 1834 the British imperial yard was destroyed by fire and when a new standard had been prepared, copies of it were made, two of which were presented to the United States in 1856. These copies were compared with the Troughton scale, and the latter was found to be 0.00083 inch longer than the new imperial yard at the standard temperature of 62° F. One of the copies was then accepted as standard by the United States Office of Standard Weights and Measures in place of the Troughton scale. This copy of the imperial yard was the standard on which all measurements of length in the United States were thereafter based until 1893, when the yard was defined in terms of the international prototype metre. The matter had been left entirely to the Treasury Department, which had adopted different yards from time to time, assumed to be equal to the British imperial yard.

The copies of the imperial yard noticeable changes relative to it when subsequently compared, and the belief that the imperial yard itself constant. Shortly after the arrival of the international prototype metre, a careful study of the relation of the imperial yard to the international metre at the Office of Standard Weights and Measures showed that the definition differed from that legalized in 1836 more than the uncertainty of the comparison. It was decided to adopt the metre as the fundamental standard of length and to express the yard in terms of it. Not only is the yard shorter than the length of the imperial yard but in addition the lines, which are 1-1000 of an inch wide, are much narrower for present requirements. On the other hand, the international metre and its copies are more rigorous requirements of modern times. The kilogram was also declared to be the fundamental standard of weight. The standards of the United States are independent of the British standards, but in part differ from them. The prevailing standards of weights and measures in common use are identical with the British imperial standards, therefore, erroneous. The United States yard is slightly longer than the imperial yard; this inequality extends to all of its multiples. The present matter of the United States is the national prototype metre No. 27 and the national program No. 20, received by the President of the United States on 2 Jan. 1890. The Bureau of Standard Weights and Measures has prepared accurate copies of the international metre and kilogram which are the standards of length and weight for use in the entire world. The latter standard is kept at the International Bureau of Standard Weights and Measures in accordance with the International Metric Convention of 1875, by the leading countries of the world. The countries jointly maintain and direct the work of this bureau through official representatives forming an international committee of eminent scientific men.

The units of length and the derived units of area, volume and capacity are derived from the international metre in the ratio of 39.37 inches (Law of 28 July 1866) to the metre. The Office of Standard Weights and Measures and the Bureau of Standards which that office have used the international metre (by order of 5 April 1893). This action fixed the international metre as much as the reference standard of length and unalterable as human skill can make it. Besides the yard, the unit of length most universally employed in the United States at the present time are the inch and the mile.

The "inch" is the 1-36 part of the yard. It has been in use since ancient times. Its name (derived from the Latin *uncia*, the 12th part) occurs in Anglo-Saxon in the form of *ynce*. It probably was used only as a convenient subdivision of the yard. Lengths shorter than one inch are usually expressed in fractions of an inch. In the arts of subdivision are in common use the binary subdivisions, half and quarter inch, but machinists also divide the

tenths, hundredths and thousandths. The inch is usually denoted by the symbol " ; but botanists use the symbol ' for the inch. The "miner's inch" is a rather vague unit for the flow of water varying from 1.36 to 1.73 cubic feet per minute, and is the flow of water through a single square inch of orifice under varying heads of water. The "inch or gauge of cream" is fixed by Iowa statute as equal to one-half gallon.

The "foot" is legally defined as one-third of the yard or 12 inches. As its name implies it was probably based on the length of the human foot. Almost every nation, ancient and modern, has had a unit called the "foot," its value differing somewhat, as might be expected with a unit of so crude an origin. Most countries, however, have now adopted the metric system, the foot being discarded as an official measure, though universally used in English countries. Lengths shorter than one foot are usually expressed in inches and fractions of an inch, but among surveyors and civil engineers it is quite common to use decimal fractions of the foot. The foot is generally denoted by the symbol ' , but botanists use the symbol ° to denote feet. Some artisans use the foot and the inch but not the yard, others the yard and its binary divisions, but not the foot or inch. Thus the foot and inch are used to the exclusion of the yard in building, while the yard and its binary subdivisions to the exclusion of the foot and inch in measuring cloth.

The "statute" or "land mile" is the unit most commonly used for longer distances and is equal to 5,280 feet. The name is from the Latin *mille passuum*, 1,000 paces, the Roman pace being a double step and consequently about five feet in length. This mile was used by the Anglo-Saxons. Almost every European nation has had a unit called the "mile" but widely at variance with one another, ranging from about two-thirds of the United States mile (Holland) up to seven United States miles (Norway). The old British statute mile was about 300 feet shorter than the United States mile but now is the same.

The following units of length are used in special work and are arranged in the order of their magnitude. Metric units are not included, as they are for the most part official only, and not generally in use in commercial and industrial life. See METRIC SYSTEM.

Mil (.001 inch) is used in electrical work, especially in indicating the cross section of wires.

The point (1-72 inch) is used in designating the sizes of type, the point system designating the sizes of type by the number of seventy-seconds of an inch height of the type face. The em is a unit of measure used in composition and varies with the size of the type, usually being considered as the square of the face height.

The line (1-12 inch) is little used, mechanics preferring to divide the inch into tenths, hundredths and thousandths. It is used by printers and by botanists, the latter denoting the line by the symbol ". The line "button measure" is 1-40 inch as defined in the tariff act.

The barleycorn (one-third inch) is an old unit still surviving in shoemakers' shoe sizes, these being graded by thirds of an inch or barleycorns, in a system of 13s.

Four units based upon the "hand" are sometimes used. These are the nail (two and one-fourth inches) for measuring cloth, originally the distance from the end of the thumb nail to the joint at the base of the thumb, and later fixed as 1-16 yard; the palm (three inches) includes the breadth of the hand exclusive of the thumb; the hand (four inches), originally the breadth of the palm, is used in measuring horses and is almost exactly one decimetre; the finger (four and one-half inches) is about the length of the middle finger and is only used as a rough unit in cloth measure. This should not be confused with the finger breadth used in measuring charges of powder.

The surveyor's link (7.92 inches) is the length of one link or 1-100 part of a surveyor's chain, and is used in the survey of lands.

Quarter (nine inches) is sometimes used in measuring cloth (more frequently in Great Britain) to designate a quarter of a yard. A unit of the same length called the span was originally half a cubit, but probably has not been used in modern times as an officially recognized unit.

The engineers' link (12 inches) used as a unit in engineering is the hundredth part of the engineers' chain and is decimally divided. The 10th of the engineers' link is 1.2 inches.

The pace is a conventional unit for measuring distances and is the length of a stride measured from the heel of one foot to that of the other; a full pace measures about one yard. This is the value of the United States military pace, double time, with a cadence of three steps a second. The regulation military pace quick time is 30 inches with a cadence of two steps per second. The Roman pace was a double step of about five feet.

The English ell, a unit still referred to but seldom used, having a value of 45 inches, varying, however, in different places. The Flemish ell of 27 inches is still in use commercially in the Low Countries.

The fathom (six feet) is used in measuring depths of water or mines. The name comes from an Anglo-Saxon word *faethm*, signifying "embrace," and originally meant the length of rope between the two hands when the arms were held outstretched.

The rod, perch or pole is equal to five and one-half yards and is used in measuring land. It has varied in different places from five to eight yards and is supposed to have been the length of the ancient goad used to measure the width of the first furrow.

The surveyors' or Gunter's chain (22 yards) was so chosen that 10 chains square might exactly equal one acre. This chain is the official unit prescribed formerly for the use of surveyors surveying public lands under the supervision of the surveyor-general and now often used in relocating old surveys.

The engineers' chain (100 feet) is used in engineering, and is decimally divided into feet, tenths and hundredths of a foot. The use of the two chains in many cases for the same land for different purposes requires reduction tables. On account of the direct relation to the foot, the engineers' chain is becoming very widely used.

The bolt for measuring cloth is generally given as 40 yards, though the name means simply a roll of definite length. The customary

length of the bolt varies with different fabrics and manufacturers.

The skein for yarn is often defined as 120 yards. Its length varies, however, according to the material and the locality. Consult the United States Conditioning and Testing Company's 'Textile Tables' (New York 1914).

The United States cable's length (720 feet), used by mariners, is 120 fathoms as recognized by the United States navy.

The furlong (220 yards) originally meant "length of a furrow," supposed to be the distance oxen could plow without stopping to rest.

The hank is a unit of length for yarn. In the United States the length of a hank of cotton is usually 840 yards, while that of linen is 3,000 yards; different lengths, however, are also in use under that title.

The nautical mile or geographical mile has been defined as 1-60 part of the length of a degree of a great circle of the earth. Since the earth is not a perfect sphere, however, the degree varies in length and this has led to much confusion in usage regarding the nautical mile. The definition accepted by the United States Coast and Geodetic Survey (consult Report of 1881, Appendix 12) is as follows: The 1-60 part of the length of a degree on the great circle of a sphere whose surface is equal to the surface of the earth. This makes the length of the nautical mile 6,080.20 feet or 1,853.248 metres. The uncertainty in the dimensions of the earth affects the last decimal place given. The nautical mile is often miscalled "knot." The latter term, however, is not a measure of length, but a measure of speed, equal to one nautical mile per hour. The admiralty "knot" of Great Britain is 6,080 feet.

The league is equal to three miles, the land league being equal to three United States statute miles (15,840 feet) and the United States marine league to three nautical miles (18,240.6 feet). Its value varies in different countries. The marine league is the distance from shore over which a country has jurisdiction under international law.

The degree is equal to about 60 nautical miles.

The astronomical unit, equal to the mean radius of the earth's orbit or nearly 93,000,000 miles, is sometimes used in stating astronomical distances.

In stating interstellar distances it is sometimes found convenient by astronomers to use the light year, being the distance traversed by light in one year, or 65,700 astronomical units.

Besides the measures of length given above, there are numerous very special methods of denoting length in case of special commodities. The thickness of sheet iron and steel is denoted by a system of arbitrary gauge numbers. The numbers in use differ for different products. On 3 March 1893 Congress passed an act establishing a standard gauge for sheet and plate iron and steel for use in the customs service. In this system the gauge numbers indicate thickness, or the weight per unit area. Sizes of wire are also denoted by a special system of arbitrary gauge numbers. The number of different systems which have been used is quite large. Pfeilschmidt's 'Wire and Sheet Gauges of the World' gives comparative tables for 11 systems of wire gauges. At present the most common

gauges in use in this country are the Sharp gauge and the Birmingham (See WIRE). The fineness or count of yarn is denoted by a system of numbers "counts" which indicate usually the hanks of the yarn in question which one pound. Thus No. 10 yarn (English yarn and spun silk count) is a yarn fineness that 10 hanks (of 84,000 yards) required to make a weight of one pound. No. 1 wool (Aberdeen count) is a spindle (of 14,400 yards) shall weigh one pound. There are about 24 different systems in use, and in order to introduce uniformity in counting textile yarn throughout the international metric count was adopted at the International Paris Conference (according to this count, No. 1 means 1 gram of 1 metre will weigh 1 gram, and No. 100 yarn will weigh 1 gram).

In addition to the above there are a number of special systems of measuring particular commodities such as hats, nails, cordage, books and other numerous for description.

The units of superficial measure are usually the squares of the linear units, such need but little comment. The square inch (.7854 square mil) is the area of a circle of 1 inch in diameter. One circular mil is 1,000,000 circular mils, and one square inch contains 1,273,240 circular mils. The square inch is the most common small unit of area in measuring pressures, strengths and properties of materials, and in engineering analysis and many other purposes. The square foot (144 square inches) is also in use. It is the basis of the board foot and cubic inches of undressed lumber, measured as one square foot of one inch in thickness is its equivalent. The "square" is a unit of carpentry for flooring, ceiling and contains 100 square feet, architects' measure.

In surveyors' measure 1 acre = 4840 square feet = 160 square poles = 100,000 square links. The acre (4840 square feet) was probably as much as a man could till in a day and therefore of a definite extent until later times. It is a unit of the same order as the French *journal* or *Morgen*. The acres of various countries differ in size, for example, the Irish acre is 7,840 square yards; the Scottish acre is 4,840 square yards; the Cheshire acre is 1,280 square yards; Cunningham acre and the Irish acre.

In subdividing public lands in the United States, the lands are laid out in townships = 36 sections or square sections = 23,040 acres. The "homestead" is a free grant of public land, the maximum area of one-quarter section = 230.4 acres. In the Philippine Islands, the "homestead" is 64 hectares, which is almost the same as defined above.

Among the more important units of volume are the cubic inch, the cubic foot, the cubic yard and the cubic mile. The cubic inch is the smallest unit of volume measured directly on linear units. It is very common in engineering to express volumes of solids or other solids. In some States, such

ington and Colorado, the cubic foot is established by statute as the legal unit for measuring the volume of water. A special system of units is used in the measurement of wood; 144 cubic inches or one foot square of one inch board is expressed as one board foot. A timber foot, however, is 1,728 cubic inches or one cubic foot. A cord foot is a pile of wood 1 by 4 by 4 feet. A cord of wood is 8 cord feet. In the lumber business boards are usually bought and sold by the 1,000 board feet to simplify computation. In New Hampshire, a measure for lumber was adopted in 1866 based upon an "imaginary cubic foot" equal to about 1.4 cubic feet. This unit is also used in parts of Maine and Vermont. Round timber is measured as follows: "A stick of timber 16 inches in diameter and 12 inches in length shall constitute one cubic foot, and the same ratio shall apply to any other size and quantity. Each cubic foot shall constitute 10 feet of 1,000 board feet." In the practical use of this rule it is customary to consider 115 cubic feet equivalent to 1,000 board feet, instead of 100 cubic feet, according to the wording of the statute. In this case the diameter is taken at the middle of the log inside the bark. If the diameter is measured at the small end of the log, 106 cubic feet are allowed for 1,000 board feet. The New Hampshire rule is called the Blodgett Rule. The Doyle is the standard of log measurement in Arkansas for logs cut and sold or hauled. A large variety of log rules is in use throughout the country. These are locally accepted as standards, but they differ among themselves in so confusing a manner as to make it impossible to give an accurate and complete statement concerning them. The cubic yard is used largely in engineering and in computing grading, cuts and fills, a cubic yard being equal to about one load.

The perch, in addition to being a unit of length and a unit of area, is also widely used as a unit of volume of brickwork and masonry. The perch of brickwork, however, is a widely varying unit, ranging from  $16\frac{1}{2}$  cubic feet to 25 cubic feet. In Colorado it is  $16\frac{1}{2}$  cubic feet, in Philadelphia 22 cubic feet, 25 cubic feet in North and South Dakota,  $24\frac{3}{4}$  cubic feet in other places. The latter perch is equal to a section of brickwork 1 by  $1\frac{1}{2}$  feet by  $16\frac{1}{2}$  feet or one perch in length.

A cord of masonry is usually reckoned at 100 cubic feet, although in some cases it is 96 cubic feet.

The cubic mile is used in expressing very large volumes, such as the silt carried by rivers.

**Liquid Measure.**—The fundamental unit of liquid measures in the United States is the wine gallon of 231 cubic inches—a unit abandoned by England in 1824, but now generally adopted by the various States of the Union. The British Imperial gallon measures 277.274 cubic inches, and is the volume of 10 pounds of water at 62° F. The liquid measures of the United States unfortunately bear no relation to those of England. Much confusion is occasioned by the use of the ambiguous term gallon, as there are in the United States the wine gallon (231 cubic inches), the ale, beer or milk gallon (282 cubic inches), and the dry gallon, besides the "proof gallon," the unit for internal revenue taxation. The "proof gallon" is a wine gallon of spirits containing one-half its volume

of nearly pure alcohol at 60° F. and is the basis for computing the United States internal revenue tax. For example, a gallon of spirits containing 40 per cent alcohol would be 80 per cent proof and the number of proof gallons is computed by multiplying the per cent of proof by the number of wine gallons. Wisconsin and Connecticut still retain the dry gallon of 282 cubic inches as a legal standard. New Hampshire and Minnesota definitely retain the ale, beer or milk gallon of 282 cubic inches, and Maine definitely mentions the same unit among its list of State standards. A Minnesota statute provides that the "Beer and milk measures shall contain the following capacities: The gallon shall contain 282 cubic inches. The half gallon shall contain 141 cubic inches, and the quart one-half as much, and the pint one-half as much as the quart." The milk gallon thus established is 51 cubic inches larger than the standard gallon used more generally throughout the country. There are thus three different quarts, the dry quart derived from the Winchester bushel, the liquid quart derived from the wine gallon, and the liquid quart derived from the beer or milk gallon. The differences, of course, extend proportionately to all the multiples and subdivisions of these units. The ordinary liquid measures are usually 1 gallon = 4 quarts = 8 pints = 32 gills. In addition to the capacity measurement by volume, the legal weight of a gallon of certain commodities have been fixed by statute in some States, and in several cases by Congress for certain purposes. Thus 12 pounds of strained honey is a legal gallon in Nebraska,  $6\frac{1}{2}$  pounds of kerosene (Kansas), and  $7\frac{1}{2}$  pounds of kerosene in Ohio, 11 pounds of sorghum molasses (Indiana), 11 pounds of maple syrup (New York), 8 pounds of castor oil (Kansas) are all legal gallons of the products named. These legal weights differ among themselves, and do not accord with the true volume of one gallon of 231 cubic inches.

The subdivisions of the gallon, the quart, pint and gill are largely used in trade. In addition to the general liquid measures enumerated above, apothecaries have a special system of capacity measures based on the volume of the United States liquid pint of 28.875 cubic inches. One pint = 16 United States fluid ounces = 128 United States fluid drams = 7,680 United States minims.

The minim is the smallest of the United States units of volume and is about 0.00376 cubic inches. A minim of pure water weighs about 0.95 grains and corresponds to the "drop," which it approximates in size. The United States minim is about 4 per cent larger than the British Imperial minim. It is denoted by the symbol  $\mu$ .

The drop varies from 0.02 to 0.1 cubic centimetre and is not a fixed unit, but is convenient for use in dispensing very small quantities of liquids. It is not subdivided and its size depends upon the liquid and the method of dropping. The ordinary form of drop pipette of the ophthalmologist delivers drops of about a half United States minim.

The United States fluid dram (60 minims) is equal to one-eighth United States fluid ounce, its volume differing from the volume of one avoirdupois dram of water, from the volume of

one apothecaries' dram of water (by weight), and is about 4 per cent larger than the fluid dram in use in Great Britain. It is about 4 cubic centimetres, or an average teaspoonful, and is denoted by the symbol *f*3.

The United States fluid ounce (480 United States minims) is the 1-16 part of the wine pint and has a volume of about 1.8 cubic inches. It differs from the British unit of the same name as well as from the volume of the avoirdupois ounce of water and the troy or apothecaries' ounce of water. Other measures of less definite character are often found convenient, such as the teaspoonful, dessertspoonful, tablespoonful, wineglassful and teacupful. They do not contain exactly the quantities usually given arbitrarily, but more exactly the common spoonfuls contain the following quantities: A tablespoonful, 5 fluid drams or 20 cc.; a dessertspoonful, 2 fluid drams or 10 cc.; a teaspoonful, 60 minims or 5 cc.

**Dry Measures.**—The dry measures in general use in the United States bear no direct relation to the liquid measures of this country or Great Britain. The following are the ordinary units of dry measures: One bushel = 4 pecks = 32 dry quarts = 64 dry pints. The fundamental unit is the Winchester bushel, a unit abandoned by England in 1824. The Winchester bushel had a capacity of 2,178 cubic inches. In the United States the name Winchester has been attached to the London bushel with a volume of 2,150.42 cubic inches and is about 69 cubic inches or 3 per cent smaller than the Imperial bushel of Great Britain—a proportionate difference existing in the subdivisions of the bushel. Conflicting State laws render difficult an adequate statement of the status of the "bushel" in this country. Although the standard Winchester bushel contains 2,150.42 cubic inches, Nebraska has established 2,150 cubic inches as the volume of a legal bushel for that State, and other States have made similar changes. Several States adopted the old ale or milk gallon as the capacity of the dry gallon, this being about 5 per cent larger than the corresponding unit derived from the Winchester bushel. Moreover, special bushels have been legally established in many States for particular products, such as the charcoal bushel, which in Connecticut is 2,748 cubic inches, in Colorado 2,500 cubic inches, in Kansas 2,564 cubic inches, in Pennsylvania 2,571 cubic inches and in Minnesota 2,419.5 cubic inches (or  $\frac{1}{2}$  basket). In Vermont "one bushel and three-quarters of a peck" are "deemed a bushel of charcoal, lime, or ashes." In some places five pecks constitute a bushel of "screened lump coal." A lime bushel in Minnesota is 2,688 cubic inches. In Pennsylvania, however, it is equal to the Winchester bushel, although the coke bushel is 2,648 cubic inches. In the adjoining State of Ohio the coke bushel is 2,688 cubic inches. In Idaho, the bushel of fruit is defined as 2,564 cubic inches and in Missouri as 2,680 cubic inches. Some States require, furthermore, "heaped measure," others "struck measure," the heap sometimes being required to be "as high as the article will admit," and elsewhere "as high as may be without special effort or design," and in still other cases, as in Connecticut, the heaped bushel is definitely fixed as 2,564 cubic inches. The many objections to buying and selling agricultural products by volume, such as the difficulty of detecting error or

fraud, the variation in the size of the heap, the ease of packing short quantity in a given volume, the effects of expansion, moisture, or shaking and the general uncertainty of estimates of quantity based upon volume early led to the practice now quite general, of defining the bushels as definite weights for the different commodities. Unfortunately the matter was left to the several States with the result that the lack of uniformity in legislation and custom has introduced considerable confusion. Not only do the weights fail to equal the true volume of one Winchester bushel, but even for the same commodity and in adjoining States the values are widely at variance. In at least two cases the size of the bushel varies with the time of the year. For a few commodities like wheat and hard coal, the standard weight is fairly general—but for such commodities as fruits and vegetables there is but little uniformity. The values of the various bushels of apples vary by about 10 per cent and for beans and charcoal about the same proportion, the legal weights of the bushel of gooseberries or beets by about 20 per cent and for cranberries 17 per cent, for sweet potatoes and buckwheat the variation is about 28 per cent in range. The "bushel" has in fact become merely a name for a miscellaneous group of units varying from State to State and differing for the various commodities, sometimes as in at least two cases, changing with the time of the year. The uncertainty is confusing to trade and precludes the compilation of accurate statistics based upon so variable and ambiguous a term.

The barrel is a convenient receptacle for packing, transporting and storing commodities. It varies in size, sometimes being defined in terms of units of volume, 6,253 $\frac{3}{4}$  cubic inches struck measure in Massachusetts. In other cases it is fixed as a definite number of units of dry measure, 100 dry quarts in New York, five bushels in Tennessee; or in some States as a definite number of liquid gallons, 36 gallons in Arkansas, 42 gallons in Tennessee, or more commonly 31 $\frac{1}{2}$  gallons. Besides this method of definition the barrel, like the bushel and the gallon, is legally defined for certain commodities in terms of a definite number of pounds. The barrel of flour, for example, is commonly fixed at 196 pounds. Apart from this, but few States have used this method of defining the barrel and that only for a few products. One hundred and eighty pounds of shelled corn constitute a legal barrel in Connecticut, 200 pounds of pork in Indiana, North Carolina and Tennessee, 200 pounds of fish in Maine, 150 pounds of sweet potatoes in Massachusetts and 3 $\frac{1}{2}$  bushels dry measure in Louisiana. In New York and some other States the several dimensions of the standard barrel are specified, although other forms containing the same volume may be used. The dimensions specified in New York are head diameter 17 $\frac{1}{2}$  inches, stave length 28 $\frac{1}{2}$  inches, bulge not to exceed 64 inches outside measure. A barrel of crude oil is usually 31 $\frac{1}{2}$  United States wine gallons and the barrel of refined oil 42 gallons.

The hogshead (two barrels), the pipe (four barrels), and the tun (eight barrels) are more commonly not intended as definite measures but merely convenient receptacles for liquids in bulk.

The smaller units of dry measure, such as

the peck, dry quart and dry pint, are largely used in retail trade, the pint and quart being used for smaller products like berries.

**Avoirdupois System.**—The avoirdupois system of weights is used for almost all commodities except the precious metals, chemicals and jewels. The avoirdupois dram differs from the apothecaries' dram, and the avoirdupois ounce and pound differ from the troy units of the same name. Ambiguity is avoided only by properly qualifying the terms. The use of such unqualified terms as ounce, pound or ton causes great confusion owing to the uncertainty and ambiguity of the terms. The "avoirdupois pound" or "troy ounce," however, are definite units. The avoirdupois units are as follows:

One long ton = 20 long hundredweights = 80 long quarters = 2,240 pounds = 35,840 ounces = 573,440 drams = 15,680,000 grains.

One short ton = 20 short hundredweights = 80 short quarters = 2,000 pounds = 32,000 ounces = 512,000 drams = 14,000,000 grains.

The fundamental unit of the avoirdupois system is the avoirdupois pound now derived from the International kilogram, in accordance with the law of 1866 and the executive order of 1893, the value being 453.5924277 grams, on the basis of 2.204621 pounds to the kilogram. The avoirdupois pound was probably derived from the Attic mina of 6845.3 grains troy, the 1-60 part of the large Attic talent, divided by the Romans into 16 ounces of nearly the same weight as the modern ounce. Congress has never directly legalized any standard of weight except the troy pound and that only for purposes of coinage. To avoid confusion in comparisons of mass, the ratio of the avoirdupois pound to the troy pound was fixed at 7,000 to 5,760, measured in grains.

The United States avoirdupois dram (or drachm) is the 1-16 part of the avoirdupois ounce (28.3495 grams). This unit must not be confused with the apothecaries' dram (weight) which is the one-eighth part of the apothecaries' ounce or 60 grains. The avoirdupois dram is largely used in the textile industries. The avoirdupois ounce is the 1/16 part of the pound and contains 16 drams. The avoirdupois stone is a denomination often used, especially in England, and varies with different commodities, the most common value being fixed in England as 14 pounds.

The hundredweight (cwt.) is the 1/20 part of the ton. The round hundredweight contains 100 pounds and is sometimes called the "cental," while the long hundredweight contains 112 pounds. This unit is used very largely in fixing transportation rates.

The commercial ton of 2,000 pounds is in very general use throughout the United States, but 112 pounds is the legal hundredweight in many places, and 2,240 pounds the legal ton, as in England. The gross ore ton contains 2,688 pounds. Some confusion exists in the use of the word "ton," as the unqualified term may mean the short ton, long ton, gross ore ton, miner's ton, varying from 2,500 to 3,000 pounds, displacement ton of 35 cubic feet, shipping ton of 40 cubic feet, timber ton of 42 cubic feet, or register ton of 100 cubic feet. The register ton varies in different countries. Accurate statistics covering more than a single State or industry are difficult to obtain, owing to the difference in the values of these units and

methods of measurement. The tariff act defines the ton of coal as "28 bushels of 80 pounds each" equal to the long or United States ton, but the statutory ton of coal in Montana is defined as 26½ bushels of 76 pounds each. In some cases the ton is defined as a definite number of cubic feet, for example, 343 cubic feet is a legal ton of hay in North Dakota and Oklahoma, and in New Mexico the ton is defined as 380, 422, or 512 cubic feet, according to the time the hay has been stacked.

**Troy Weights.**—The troy weights are as follows: One pound = 12 ounces = 240 pennyweights = 5,760 grains. The troy pound was legalized in 1828 as the standard unit to be used by the Mint of the United States in the regulation of the coinage. In view of the confusion in the weights and measures of trade, Congress found it important to legalize some particular weight for the use of the Mint, and by the act of 19 May 1828 legalized the copy of the Imperial Standard troy pound. This copy was procured by Albert Gallatin in England in the preceding year and was received by President Adams 13 Oct. 1827. It was based upon the old Imperial Standard troy pound of 1758, legalized in 1825. This troy pound has not been recognized as a legal standard in England since 1855, and was declared illegal, with penalty attached, in 1878.

The grain is the 1-5760 part of the troy pound, and is the only unit which connects the troy system with the avoirdupois. A very old English statute (51 Henry III, 1266) provided that the English penny should weigh "thirty-two grains of wheat well dried and gathered out of the middle of the ear." Fifteen different values of the grain in different countries are cited, varying from 0.68 to 1.54 United States troy grains. The troy grain, as used in the United States, is 0.0648 gram. The diamond grain is 0.8 troy grain. The troy grain is practically obsolete in the avoirdupois measures. Fractions of the grain are usually indicated decimally.

The pennyweight is the 1-240 part of the troy pound. Some 18 different values are recorded, varying from 7.42 grams to 24 United States grains.

The troy ounce is the highest troy denomination permitted in England, and is used in stating quantities of silver and other precious metals. In assaying the troy ounce is frequently divided decimally. The silk troy ounce according to Troemner is the 1/16 of the troy pound and contains 360 grains. One hundred and seventy-five troy ounces equal about 192 avoirdupois ounces.

The units of apothecaries' weights are as follows: One apothecaries' pound = 12 ounces = 96 drams = 288 scruples = 5,760 grains. The apothecaries' pound is equivalent to the troy pound in the United States, but in England the apothecaries' weights based on the troy pound were discontinued in 1858 under authority of the medical act, and avoirdupois weights substituted in dispensing medicines. In the United States, the avoirdupois system is largely used in buying and selling drugs, although the metric system is rapidly coming into use and displacing the apothecaries' weights on account of its great convenience. The apothecaries' grain is used in compounding prescriptions of the more powerful drugs. The United

States apothecaries' scruple (20 grains) and the United States apothecaries' dram (60 grains) are still used in compounding prescriptions. The United States apothecaries' ounce (480 grains) is equal to the troy ounce. The apothecaries' pound (equal to the troy pound) is rarely used.

The units used in the weighing of diamonds are as follows: One diamond carat=4 diamond grains=64 parts. The carat is the jewellers' unit for weighing diamonds, the name referring to a small hard bean formerly used for that purpose. In view of the variation in the value of the carat in different countries, its weight was fixed by agreement of London, Paris and Amsterdam jewelers, in 1878, at exactly 205 milligrams. The following varieties of carats should be carefully distinguished: The international diamond carat of 205 milligrams, a definite unit free from ambiguity; the English diamond carat (3.2 troy grains or four diamond grains) differing, however, in different countries; the old carat (1-24 troy ounce); the gold carat (about 150 troy grains); and the gold carat, a ratio equal to 1-24 part by weight used in designating the purity of gold alloys. See also BALANCE; TONNAGE; WEIGHING MACHINES.

**WEIHAIWEI**, wā'hī'wā', China, a duty-free seaport and British naval and coaling station, in the province of Shantung, near the eastern extremity of the Shantung Peninsula, 40 miles east of Chefu. It lies on the south shore of the entrance to the Gulf of Pechili, opposite Port Arthur on the north shore, about 100 miles distant. During the Chino-Japanese War, the Japanese destroyed a Chinese fleet here and captured the town, which they evacuated early in 1898. By a convention of 1 July 1898 the port of Weihaiwei, together with the adjacent waters and some neighboring

territory, was leased to Great Britain. The leased territory included the island of Liu Kung, all the islands in the bay and a belt of land 10 miles wide along the whole coast of the bay; area, 280 square miles; pop. 120,000; but the population of the town of Weihaiwei is only about 2,500 inhabitants, being an old-time walled town. By the terms of the lease Great Britain has sole jurisdiction within the limits of this territory, but within the walls of the city, Chinese officials may exercise such authority as is not inconsistent with the defense of the territory. The British government may also erect fortifications and carry out other defensive works in a defined region lying outside of the leased territory. Chinese war-vessels retain the right to use the waters. Weihaiwei is not to be fortified, but is intended to be a naval base, place of exercise and sanatorium for the British squadron on the China station. The station is used as a flying naval base, but no troops are stationed there, and the Chinese troops that were located there were disbanded. In 1917, 639 steamers and 2,563 junks entered and cleared at Weihaiwei. The imports are mainly petroleum, flour, cotton goods, sugar, food-stuffs and coal; the exports are ground nuts and ground-nut seeds (290,687 hundred-weight in 1917), and salt fish. There is a mail service to Shanghai and Europeans seek the locality in summer to escape the heat of the region farther south. Consult Annual Report on Weihaiwei; Bruce-Mitford, C. E., 'The Territory of Weihaiwei' (Shanghai 1902); Johnston, R. F., 'Lion and Dragon in Northern China' (London 1910).

**WEIMAR**, vi'mär, Germany, the capital of the grand duchy of Saxe-Weimar, on the Ilm, 13 miles east of Erfurt. It stands in a beautiful valley surrounded by hills, on ground partly elevated and partly flat. It is irregularly built except in the suburban portions. Its notable public edifices are the grand-ducal palace, a handsome structure erected partly under the superintendence of Goethe; the so-called Red and Yellow castles, now united and occupied by several public departments; the grand-ducal library (in the Green Castle), containing 300,000 volumes and a large collection of maps; the museum; the Stadtkirche, with an altar-piece, one of the finest works of Lucas Cranach, in which he has introduced portraits of himself and Luther and Melanchthon; and the modern Gothic town-house. The public monuments comprise the Goethe-Schiller monument in bronze, statues of Herder, Wieland, the composer Hummel, the Grand-Duke Karl August and various others, and a monumental fountain. Goethe's house is now used as a Goethe National Museum, and Schiller's contains relics of its former distinguished owner. A Goethe and Schiller Archives building was opened in 1896. Goethe and Schiller are interred in the grand-ducal vault in the new cemetery. Stretching away from the palace is a fine park on the banks of the Ilm. Weimar has a gymnasium, a realgymnasium, academy of painting, school of drawing, normal school and other educational institutions. It has neither trade nor manufactures of much consequence, the manufactures of iron, wood, straw, leather and cloth being carried on to some extent, but as

the capital of the duchy it is the legislature and of all the more courts and public offices. It long sort of "German Athens" in consequence of the enlightened patronage which Karl August (d. 1828) afforded to great literary men of Germany, Schiller, Herder and Wieland. In the National Assembly of the German Empire at Weimar and there the constituent new German Republic was made at The Treaty of Versailles (1919) was Weimar during the session of the Pop. 33,000.

**WEINGARTNER**, vin'gärt-nr, Austrian composer: b. Zara, Dalma 1863. He studied at the Leipzig Conservatory having received a government scholarship in 1884 his opera, 'Sakuntala,' was put out at Weimar under the patronage of the Grand Duke. He was musical conductor at Dantzig and Hamburg in 1884-89 and was appointed court conductor at Weimar in 1890. His health compelled the resignation of his post and in 1898 he settled in Munich as conductor of the Kaim concerts. He has numerous songs, several symphonic operas 'Malawika' (1886); 'Genesis' (1890); 'Kain und Abel' (1914); 'Die Sündenflut' (1916), etc. He has written 'Die Wiedergeburt und das Märchen' (1895); 'Beyreuth 1876 bis 1896' (1900); 'Lutes' by Lusztig and by Kaim published in Berlin in 1908.

**WEINMAN**, Adolph Alexander, sculptor: b. Carlsruhe, Germany, 11 He came to the United States when he was 17 and later studied art in New York at Saint Gaudens at the Art Students League and at Cooper Union. He is a member of the National Academy, the National Society and the National Institute of Arts and Letters. In 1915 he served on the International Jury of Awards at the Panama-Pacific Exposition. Among his works are the General Sherman monument, Detroit, Mich., the Lincoln Memorial at Hodgenville, Ky., and a Wisconsin monument at the State Capitol, Madison, Wis., the Lincoln statue at the State Capitol, Frankfort, Ky., the statuette of Lincoln at the Metropolitan Museum of Art, New York, and the Indian head at the Brooklyn Museum.

**WEIR**, wēr, Harrison William, artist and journalist: b. Lewes, Delaware, May 1824; d. London, 4 Jan. 1906. He was trained in the art of wood-engraving, but turned to painting, and his first exhibition at the British Institution was in 1843. He was the last survivor of the original staff of the London News and was engaged in the 'Graphic,' 'Pictorial Times,' 'Black and White,' and other London periodicals. His authority on the correct delineation of domesticated animals, was noted for his knowledge of country life and as an illustrator of books and periodicals. He wrote and translated 'The Poetry of Nature'; 'Life in the Country'; 'Our Cats and Dogs'; 'Them', etc. Perhaps his greatest work was his work 'Our Poultry and Their History' (1903), the writing and illustration of which claimed his attention for 20 years.

**WEIR, James**, American physician and author: b. Owensboro, Ky., 17 Oct. 1856; d. there, 9 Aug. 1906. He was graduated from the University of Louisville in 1878 and studied medicine there and in New York. He published 'Religion and Lust' (1897); 'The Dawn of Reason' (1898); 'Intelligence in the Lower Animals' (1898).

**WEIR, John Ferguson**, American painter, sculptor and author, son of R. W. Weir (q.v.): b. West Point, N. Y., 28 Aug. 1841. He was a pupil of his father and became a member of the National Academy in 1866. Since 1869 he has been professor of painting in the Yale School of Fine Arts. As a sculptor he is known by his statues of President Woolsey and Professor Silliman of Yale, and in addition to many portraits he has painted 'The Gun Foundry'; 'The Forging of the Shaft'; 'The Column of Saint Mark's, Venice,' etc. He has written 'John Trumbull and His Works' (1902); 'Human Destiny in the Light of Revelation' (1903).

**WEIR, Julian Alden**, American artist, son of R. W. Weir (q.v.): b. West Point, N. Y., 30 Aug. 1852; d. New York, 8 Dec. 1919. He studied with his father and at Paris with Gérôme, became a member of the Society of American Artists in 1877 and a National Academician in 1886. Mr. Weir was one of the founders of the Society of American Artists, the first organization to rebel at all effectively against the Academy. These societies were later united and Mr. Weir at once refused the presidency of the Association of American Painters and Sculptors because it was in opposition to the Academy. He painted many kinds of pictures, subjects, still life, portraits, figures, landscapes. In his later career he was identified with the Impressionist School. Examples are to be found in the Luxembourg, Paris, and in nearly every important art museum in the United States, including the National Gallery, Washington, the Art Institute of Chicago, the Albright Gallery, Buffalo, the Pennsylvania Academy, Philadelphia, and the Brooklyn Institute. 'Breton Interior' obtained a second-class medal at the Paris Exposition of 1889. His 'Idle Hours,' now in the New York Metropolitan Museum, received the \$2,000 prize of the American Art Association. In the same gallery are 'The Red Bridge' and 'The Green Bodice,' the latter one of Weir's masterpieces. Weir's long career as an artist was marked by independence and naturalness. It was only after repeated experiments that he achieved the general recognition which the reticent, refined, and distinguished style of his maturity deserved.

**WEIR, Robert Walter**, American artist: b. New Rochelle, N. Y., 18 June 1803; d. New York, 1 May 1889. After studying under Jarvis he began portrait painting in 1821 and then studied in Florence under Benvenuti, 1821-28. In 1829 he became a National Academician and was professor of drawing at West Point 1837-79. He was of especial prominence as a historical painter and among his works are the 'Embarkation of the Pilgrims' (1845) in the rotunda of the Capitol at Washington; the 'Church of the Holy Innocents' (1847), Corcoran Art Gallery, Washington; and 'Peace and War,' painted for the chapel at West Point.

**WEIR**, a dam. See HYDRAULICS; IRRIGATION; WATER SUPPLY.

**WEIRS, Fishing.** See POUND-NET FISHING.

**WEISER**, Idaho, city and county-seat of Washington County, on Snake River, 60 miles northwest of Boise and on the Pacific and Idaho Northern and the Oregon Shortline railroads. The Intermountain Institute is located here. There are flour mills. The surrounding district is interested in stock-raising and mining. Pop. 2,600.

**WEISHAAPT, vis'howpt, Adam**, German mystic: b. Ingolstadt, 6 Feb. 1748; d. Gotha, 18 Nov. 1830. He was the founder of the Society of the Illuminati (q.v.). Educated at Ingolstadt, he there became in 1772 extraordinary professor of law and in 1775 professor of natural and canon law. His appointment to the latter post brought him into collision with the clergy, especially the Jesuits, as after the suppression of their order he became their bitter enemy, although he had been educated by them. He formed the plan of uniting a large number of men together to sustain certain perfectionist views and his instruction-room soon became a nursery of his doctrines. In 1785 he was obliged to leave Ingolstadt and retired to Gotha, where he was afterward made councillor of state by the duke. His most important writings are 'Geschichte der Verfolgung der Illuminaten' (1786); 'Das verbesserte System der Illuminaten' (1787); 'Pythagoras, oder Betrachtung über die geheime Welt- und Regierungskunst' (1790); 'Materialien zur Beförderung der Welt- und Menschenkunde' (1850); 'Ueber Staatsausgaben' (1820); and 'Ueber das Besteuerungssystem' (1820).

**WEISMANN, vis'män, August**, German biologist: b. Frankfurt-on-the-Main, 17 Jan. 1834; d. 6 Nov. 1914. After studying medicine in Göttingen University he was clinical assistant at Rostock in 1856-57 and in the course of the three years 1858-60 visited Vienna, Italy and Paris, devoting himself especially to studies in the natural sciences. He lived for a year at Schaumburg Castle as body physician to the Archduke Stephen of Austria and in 1863 went to Giessen to prosecute his zoological studies under Leuckart. Having qualified as a lecturer in the University of Freiburg, he was appointed extraordinary professor there in 1866 and ordinary professor in 1873. His first published work was a treatise on the 'Development of the Diptera' (1864). It was followed by a work 'On the Influence of Isolation on the Formation of Species' (1872) and 'Studien zur Descendenztheorie' (1875-76). This work, translated into English in 1882 by Professor Meldola under the title 'Studies in the Theory of Descent' (with a preface by Charles Darwin), treats of several important phenomena in natural history from the standpoint of a thorough believer in the doctrine of natural selection. His 'Beiträge zur Naturgeschichte der Daphnoiden' (1876-79) and 'Die Entstehung der Sexualzellen bei den Hydro-medusen' (1883) are valuable contributions to the developmental aspect of zoology. A series of treatises followed in which he developed his characteristic theories, among them being 'Ueber die Vererbung' ('On Heredity'),

'Über die Dauer des Lebens' ('On the Duration of Life'), 'Über Leben und Tod' ('On Life and Death'), 'Die Kontinuität des Keimplasmas als Grundlage einer Theorie der Vererbung' ('The Continuity of the Germ-Plasm as the Basis of a Theory of Heredity'), 'Die Bedeutung der Sexuellen Fortpflanzung für die Selektionstheorie' ('The Significance of Sexual Reproduction for the Theory of Selection'), 'Über den Rückschritt in der Natur' ('On Retrograde Development in Nature') and 'Amphimixis.' These have appeared in an English translation under the title 'Essays upon Heredity and Kindred Biological Problems' (Vol. I, 1889; Vol. II, 1892). Weismann's other works include 'Das Keimplasma' (1892), in English as 'Germ Plasm' (1893); 'Die Allmacht der Naturzuchtung' ('The Omnipotence of Natural Selection,' 1893); 'Aeussere Einflüsse als Entwicklungsreize' ('External Influences as Stimuli to Development,' 1894); 'Neue Gedanken zur Vererbungsfrage' ('Fresh Thoughts on the Question of Heredity,' 1895); and 'Ueber Germinalselektion' ('On Germinal Selection,' 1896). See HEREDITY; WEISMANNISM.

**WEISMANNISM**, the essential teaching of August Weismann (q.v.), sometimes referred to as "Neo-Darwinism." Interest and controversy have gathered mainly round his answer to the question, "How is it that a single cell of the body can contain within itself all the hereditary tendencies of the whole organism?" In all theories of heredity (q.v.) biologists have assumed that characters acquired by the individual are transmitted to offspring. This Weismann denies and while biologists have concerned themselves with speculation as to the mode by which such transmissions are effected, he challenges them to prove that they are effected at all. The burden of proof is thus thrown upon his opponents, whose assumptions must give way to experimental evidence, which alone can determine, and that only after protracted record of cases, whether individually acquired characters are transmitted or not. Death, he contends, is not a primary attribute of living matter; the protozoans, or one-celled organisms, being immortal in so far that they do not die naturally. The protozoan, a microscopic jelly-like, apparently—not really—structureless mass, with no seeming unlikeness of parts, multiplies by division. Each half becomes a complete individual and grows in like manner as the whole to which it belonged, till it also divides and so on with the multiplication of protozoans *ad infinitum*. It cannot be said of either half that one is parent and the other offspring, for both are of the same age, and only, in a limited sense, as the subdivisions into separate individuals are repeated, can we speak of succession of generations. In these processes there is nothing analogous to death. "There are," Weismann says, "no grounds for the assumption that the two halves of an amoeba are differently constituted internally, so that, after a time, one of them will die while the other continues to live. Observations show that when division is almost complete the protoplasm of both parts begins to circulate and for some time passes backward and forward between the two halves. A complete mingling of the whole substance of the animal and a re-

sulting identity in the constitution of each is thus brought about before the final division? Consequently, there is no real distinction of the individual; potentiality is not absolute, immortality so long as it lasts on the earth.

While the one-celled organisms are mortal, only the reproductive cells of metazoans, the many-celled, are immortal. How does this come about? Weismann accounts for this by the failure of certain protozoans to divide equally, whereby unlikeness of parts in position of parts resulted. In multicellular organisms were probably formed by the failure of similar cells, but these units were not original homogeneity. As the result of unequal relative position there arose divisions. Some of the cells were especially fitted for the nutrition of the community, while others undertook the work of reproduction. Clearly, those on the outside, being the direct and constant action of the environment, would be the media of the builders-up of the cell-communities. The result of this cell-clustering was that the cells fell into two classes, body cells and germ-cells. While the body cells were concerned with the nutrition of the community, losing in this specialization of function their power of reproduction, that power was concentrated in the germ-cells, or, more precisely, in the germ-plasm, which is in the nucleus of the germ-cell. In the germ-cells which are the immortal metazoans. With increasing specialization of function there has been increasing differentiation of the organism, but the two-fold character of the somatic or body cells and the germ-cells has remained. The death of the individual is involved in the ultimate failure to reproduce because a worn-out tissue cannot renew itself, and because cell-division has limits. In brief, death is the penalty of complexity of structure. As it is not for the germ-cell to be, as it were, the nucleus of the whole body, and for all the body to dispatch particles to the germ-cells whence these derive their power. (the fundamental idea of Darwin's pangenesis, q.v.), the germ-cells, so essential and characteristic substances concerned, are not derived from the individual, but directly from the parent cell. Heredity, Weismann contended, is effected by the transference from one individual to another of a substance with a definite chemical and molecular constitution. In other words, by the "continuity of the germ-plasm." This germ-plasm (which, Weismann argues, runs perilously near a metazoan concept) is assumed to possess a highly but extremely stable structure, so that it absorbs nourishment and grows without the least change in its cellular structure. Of this germ-plasm Weismann assumed that a small portion of the parent egg-cell is not used up in the construction of the body of the offspring, but reserved unchanged for the formation of germ-cells of the following generation. Variations of the germ-plasm itself, and it is upon these variations that natural selection operates. Variations are

the influence of external condition nor to use or disuse of organs, but to sexual conjugation. The process combines two groups of hereditary tendencies derived from the mingled germ-plasms of the male and female parents, resulting in those individual differences which form the material from which new species are produced by the action of natural selection. Those differences multiply in geometrical ratio.

The sum of the matter is that natural selection (q.v.) is the dominant factor, that use and disuse of parts and the action of the environment count for nothing, or, at the most, for but a little. (See USE AND DISUSE). Here and there Weismann makes concessions as to the modifying influences of body cells on the germ-cells, and as to the ultimate origin of hereditary individual differences in the direct action of surroundings, which are a partial surrender of his main contention as to the isolation of the germ-plasm. It is not easy to reconcile the theory of an insulated germ-plasm with the ceaseless manufacture, secretion and expulsion of germ-cells, the materials of which are derived from the materials nourishing the entire organism; nor with the subtle influence of the nervous system on the reproductive organs.

Perhaps the most serious difficulty in Weismann's theory is in the reconciliation of psychological evolution with the continuity of the germ-plasm. For the researches of Spencer, Balfour and others have demonstrated that the nervous system had its origin in modifications of the primitive skin due to the direct action of the environment. Be this as it may, the wide-reaching sociological significance of the doctrine of heredity—which may be regarded as the physical correlate of determinism—gives an importance to the labors of Weismann that cannot be overrated, and makes urgent the record of extended observations on the lines already laid down by Galton.

**Bibliography.**—Haeckel, 'Generelle Morphologie' (1866); Darwin, 'Variation Under Domestication' (1868); Brooks, 'The Law of Heredity' (1883); Virchow, 'Descendenz und Pathologie' (Virchow's Archiv, ciii, 1886); Eimer, 'Die Entstehung der Arten' (1888); Galton, 'Natural Inheritance' (1889); Romanes, 'An Examination of Weismannism' (1893); Spencer, 'A Rejoinder to Professor Weismann' (1894); Hertwig, 'The Biological Problem of To-day' (1894). For critiques of Weismann, consult Eimer, Virchow, *op. cit.*; Spencer, 'Factors of Organic Evolution' (1886); McKendrick, 'General Physiology' (1888) and the files of *Nature*.

**WEISS, Charles Andre**, French authority on international law: b. Mulhouse, Alsace, 30 Sept. 1858. He took his LL.D. at the University of Paris in 1880 and later became a member of the faculty there. He has been prominently connected with various societies and commissions dealing with international law, and has written voluminously and with praiseworthy clarity upon the subject. He is a chevalier of the Legion of Honor. Author of 'Traité élémentaire de droit international privé' (1882); 'Traité théorique et pratique de droit international privé' (1892); 'Le droit civil et la législation comparée' (1900); 'Manual de droit international privé' (1905); 'The Violation by Germany of the Neutrality of Belgium

and Luxemburg' (1915); 'La Reparation des dommages de guerre' (1917), etc.

**WEISS, John**, American clergyman: b. Boston, 28 June 1818; d. there, 9 March 1879. He was graduated at Harvard in 1837; in the winter of 1842-43 studied at Heidelberg, Germany; was graduated in the last-named year at the Harvard Divinity School, and settled as minister of a Unitarian church in Watertown, Mass. His anti-slavery utterances having disturbed the harmony of his pastorate, he resigned, and in 1847 became minister of a Unitarian society in New Bedford, Mass., but was soon compelled by reason of ill health to retire. Again in 1859-70 he was minister of the Watertown church, from which he finally withdrew in order to pursue his literary work. He was one of the most brilliant of the New England reformers and transcendentalists, and his writings display a mind at once mystical and scientific, strongly rationalistic on religious subjects, but endowed with a fine poetic power of interpretation, which he applied to religious history and symbolism, as well as to questions of philosophy and life, to which he brought prophetic insight and fervor. His publications include 'Æsthetic Prose' (1845), a translation of Schiller's philosophical and æsthetic essays; 'Life and Correspondence of Theodore Parker' (1864); 'American Religion' (1871); 'Wit, Humor, and Shakespeare' (1880); and 'The Immortal Life' (1880).

**WEISSENFELS**, vis'sen-fêls, Germany, town in the Prussian province of Saxony, on the Saale River, 14 miles southwest of Leipzig, on the main line of the railroad from Bebra to Frankfort-on-the-Main. It was the capital of the duchy of Saxe-Weissenfels in 1656-1746. The Augustusburg Palace, built in 1664-90, is now used as a military school. There are deposits of lignite and sandstone in the vicinity. Manufactures include machinery, ironware, shoes, paper, sugar and electrical appliances. Pop. 33,581.

**WEITENKAMPF, Frank**, American connoisseur of prints: b. New York, 13 April 1866. He studied at the Art Students' League, New York. He is chief of the art and print departments of the New York Public Library, where he has done notable work in arranging continuous exhibitions of carefully selected prints; and he has also done considerable art propaganda work in disseminating information concerning prints through the press. In 1914 New York University gave him the degree L.H.D. He has prepared many pamphlets cataloging and describing prints; has contributed to various encyclopedias and to the 'Standard Dictionary'; and is author of 'How to Appreciate Prints' (1908; new ed., 1916); 'American Graphic Art' (1912).

**WEITLING, Wilhelm Christian**, German communist: b. Madgeburg, Prussia, 1808; d. New York, 25 Jan. 1871. He early became an advocate of communism, traveling and lecturing in its behalf. He took part in the Revolution of 1848 and afterward came to the United States. He founded the Socialist society known as Arbeiterbund in New York, and was connected with the establishment of a communistic colony in Wisconsin, although he lived in New York. Author of 'Guaranties of Harmony and

Freedom' (1842); 'Humanity as It Is and as It Should Be' (1845), etc.

**WEITSPEKAN** (wit'spĕk-ən) **INDIANS** (from *Weitspek*, the name of one of their towns). A linguistic stock of North American Indians, comprising several small tribes collectively known as the Yurok, occupying the lower Klamath River in California from the mouth of the Trinity down. On the coast Weitspekan territory extends from Gold Bluff to about six miles above the mouth of the Klamath. The Chilula are an offshoot of the Weitspek, living to the south of them, on Redwood Creek to a point about 20 miles inland, and from Gold Bluff to about midway between Little and Mad rivers.

**WELBECK ABBEY**, England, the seat of the Duke of Portland, in Nottinghamshire, three miles south of Worksop. It occupies the site of an old Premonstratensian abbey and came into the possession of the Portland family by marriage in 1734. It stands in a park 10 miles in circumference and is a stately Palladian edifice of mainly the 17th and 18th centuries, but was greatly enlarged about 1864 by the fifth duke, to whom it owes its semi-underground picture gallery, ballroom and riding-school, the last 385 feet long, 104 feet wide and 51 feet high.

**WELCH, Ashbel**, American civil engineer: b. Nelson, N. Y., 4 Dec. 1809; d. Lambertville, N. J., 25 Sept. 1882. He was engaged as an engineer on the Lehigh Canal in 1827; was made chief engineer of the Delaware and Raritan Canal in 1835 and afterward planned the route and constructed the Belvidere and Delaware Railroad. In 1862 he became manager of the Pennsylvania Railroad lines in New Jersey and subsequently was made president. He introduced the block system (q.v.) in railroading in the United States and published papers on economics and civil engineering. He was elected president of the American Society of Civil Engineers in 1881.

**WELCH, Herbert**, American clergyman and educator: b. New York City, 7 Nov. 1862. He was graduated at Wesleyan University 1887 (A.M., 1889; D.D., 1902; LL.D., 1906; B.D., from Drew Theological Seminary 1890). Studied at Oxford University, 1902-03. He entered the ministry of the Methodist Episcopal Church, joining the New York East Conference in 1890. After several pastorates in important churches in and around New York and Brooklyn he was elected president of Ohio Wesleyan University, Delaware, Ohio, in 1905. In 1916 he was elected bishop and assigned to Korea. He was president of the Ohio Association of College Presidents and Deans, 1907-08; president of the Methodist Federation for Social Service, 1907-12 and since then vice-president. He has also been a member of the boards of managers of several of the denominational societies of his Church. In 1914 he was fraternal delegate to the Methodist Church of Canada. He edited 'Selections from the Writings of John Wesley' (1901).

**WELCH, Philip Henry**, American humorist: b. Angelica, N. Y., 1 March 1849; d. Brooklyn, N. Y., 24 Feb. 1889. From 1882 to 1884 he was attached to the staff of the Rochester *Post-Express*, and then removing to New York was

employed by the *Sun*. He was among the humorous press writers and was an able satirist. He pub *Tailor-Made Girl*' (1888); and '*S*' (1889).

**WELCH, William Henry**, Anatomologist: b. Norfolk, Conn., 8 Apr. was graduated from Yale in 1870 at College of Physicians and Surgeons, New York in 1875. He studied pathology becoming in 1878 demonstrator of the Bellevue Hospital Medical College, New York. Since 1884 he has been a professor of pathology at Johns Hopkins Univ. is an eminent authority on bacteriology and is the author of '*Pathology of Fever*,' '*Thrombosis* and numerous professional papers. Huxley lecturer at Charing Cross, London, in 1902, and served as president of the Congress of American Physicians in 1897.

**WELCH, W. Va.**, town and county seat, MacDowell County, situated on the River and on the Norfolk and Western road, 71 miles east southeast of W. Va. has the county buildings, post office, several churches, school, etc. Agriculture is the basic industry of the surrounding country which the town serves as a shipping point. Pop. about 600.

**WELCKER, vĕl'kĕr, Friedrich**, German archæologist: b. Grünberg, Nov. 1784; d. Bonn, Rhenish Prussia, 1868. He was educated at Giessen; in 1809 was a tutor in the family of V. Humboldt at Rome. In the last-named position he resigned in 1819 to accept of archæology at Bonn. Political disturbances in 1832 caused his dismissal, but he afterward recalled and occupied that position when he retired. As a classicist Welcker held high rank; his extensive knowledge of Greek art, history and mythology great and lasting value. '*Die griechische Götterwelt mit Rücksicht auf den epischen Geordnet*' (3 vols., 1841) is perhaps his best work. He prepared editions of Alphonso's '*Philostratus*' '*Imagines*,' Hesiod's '*Theogony*' and '*Kleine Mythologie*' (6 vols.). Among the most notable other works are '*Aeschyleische Tragoedien*' (1824); '*Der epische Cyclus*' (1835); '*Denkmäler der griechischen Kunst*' (1849-64); '*Griechische Literaturgeschichte*' (1863), etc. Consult '*Kekulé, Friedrich Gottlieb Welckers*' (1880).

**WELD, Theodore Dwight**, American philanthropist and educator: b. Hampton, N. Y., 23 Nov. 1803; d. Hyde Park, N. Y., 1895. He was the son of Ludovicus (Clark) Weld, and of lineal descendant of the American Revolutionary War hero, Nathaniel Edwards. He entered Phillips Exeter Academy, but left school because of near-sightedness. He was one of the 63 originators of the American Anti-Slavery Society in 1833 was secretary of that society; he was agent of the Society to promote the cause of Labor in Schools. He entered Lane Theological Seminary, Cincinnati, Ohio, and organized youths evenings. He was consistent in his unselfish charities and fair dealings,

hesitate to denounce slavery and the slave trade openly and publicly. He left the seminary when the trustees suppressed the local anti-slavery organization and began a course of lectures. He was repeatedly mobbed, but his commanding presence and athletic attainments, as well as his fearless and wonderful eloquence, enforced respect; at Granville, Ohio, when advised that the church would be burned if he lectured as advertised, he informed the trustees that he would then speak from its foundations; to threatening letters he replied: "Come, but bring your own winding sheets, which I cannot supply"; six undisturbed lectures followed. At Painesville, Ohio, such was his eloquence that the leader of the mob kicked in the head of the bass drum with which he had thought to drown the speaker's voice. In 1836 his voice partially failed him, but he taught school and used his pen vigorously. In 1838 he married Angelina Emiline, daughter of Judge John Grimke, of South Carolina, who, having become a Quaker in 1835, emancipated her inherited slaves. He edited the American Anti-Slavery Society's publications in Washington, D. C., and was confidential adviser with Congressmen who favored abolition of slavery in the District. In 1854 he established a school at Englewood, N. J., for the joint education of white and black youth; in 1864 removed to Hyde Park, Mass., and aided in founding the historical society, the public library and the school system.

**WELDING** is the intimate union produced between the surfaces of two pieces of metal, when heated to the point of fusion and hammered or pressed together. To weld a bar of iron to another piece of iron requires an intense white heat and the use of a flux or welding compound. Steel can be welded at a slightly lower temperature than iron. The essential condition to a good weld is that the plastic state of the metal shall be maintained for a short time without its melting away or burning. Borax, ammonium chloride, potassium carbonate and various alkalis are used as fluxes. (See **ELECTRIC WELDING**). Some solids can be welded by pressure, as graphite, coal, asbestos, etc. Horn may be welded between hot metal plates by pressure, by using hot water or wet cloth to protect the horn surfaces. Consult Kantny, T., 'Autogenous Welding and Cutting' (New York 1915).

**WELDING, Electric.** See **ELECTRIC WELDING**.

**WELDING, Gas (Oxy-Acetylene).** **Development of Oxy-Acetylene Processes.**—Gas welding consists of melting the edges of two pieces of metal so that they run together and become solid when cold. A good weld requires a very intense flame, such as is obtained from acetylene and oxygen. By the oxy-acetylene process two sections of like metal can be so united that the two members form a homogeneous whole, so perfect that the weld cannot be distinguished when machined. Examination reveals the same uniformity of metallic texture throughout the weld. In this important respect oxy-acetylene welds are recognized as the highest examples of the science of welding. Oxy-acetylene welding, now generally spoken of as oxwelding, has attained a very important and practically indispensable place in the iron and steel industry.

It is used in practically all forms of construction and manufacture, and is applied to almost countless operations in production and repairs. It is extensively used in low and high pressure pipe-lines and for butt-welding of metal tubing. Ninety per cent of the railroads in the United States use this process in their shops and on the road, and approximately 35,000 locomotives now in service have welded joints that withstand standard steam pressure. The extent to which oxy-acetylene welding was used during the World War of 1914-18 in the manufacture of depth bombs, torpedo casings, poison gas tanks and other supplies and munitions in which speed and volume of production were vital is well known. Practically all of the enormous number of high explosive and other large shells manufactured in America during the war were made from steel billets cut to size by the oxy-acetylene process. In the field, army trucks and repair shops were universally equipped with oxy-acetylene welding and cutting outfits, and in France numerous depots were established where broken and damaged metal parts were quickly repaired by oxy-acetylene and put back into service. In peace times the oxy-acetylene cutting torch is extensively used in the wrecking of steel structures, in cutting of scrap to sizes for the cupola, in the cutting of armor plate of any thickness, and in fact wherever steel and wrought iron are to be cut, from the largest shipyard down to the smallest industrial plant.

The equipment required for oxy-acetylene welding consists of a cylinder or tank of oxygen, a tank of acetylene, two regulators or reducing valves (one each for the acetylene and oxygen tanks), a welding blowpipe and two pieces of hose to connect the blowpipe to the regulators. The cutting equipment is very similar excepting as to the type of the blowpipe used and special hose to sustain the higher oxygen pressure used in cutting. Of the gases adapted to blowpipe use, acetylene and oxygen are by far the most extensively applied, owing to their special fitness industrially, both being obtainable in portable cylinders at low cost. Acetylene contains 1,475 B.T.U.'s, and this very high heat content, together with its endothermic characteristics, conduces to speed in accomplishing a given quantity of work as well as being a material factor in the excellence of the work. Acetylene was discovered by Edmund Davy, an English chemist, in 1836; but it remained a laboratory gas until the development, more than half a century later, of a practical method for producing calcium carbide in commercial quantities. Thomas L. Willson, the American electro-metallurgist, in 1891-92 conducted a series of experiments with a mixture of lime and coal tar heated to high temperature in a Heroult electric furnace, resulting in what may be termed the "commercial discovery" of calcium carbide and leading to the establishment, in 1895, of the first factory in the world for the manufacture of carbide.

In the early years of its commercial application, acetylene generated from carbide was used chiefly as an illuminating gas, and so great was the demand for acetylene for house and town lighting that the industry soon became one of considerable importance. By 1901 calcium carbide was being produced in large quantities and distributing warehouses were established

throughout the country. This was shortly followed by development of Prest-O-Lite portable acetylene cylinders containing acetylene dissolved in acetone. The convenience of portable acetylene, rendering the gas available everywhere, created a tremendous demand for acetylene in this form and resulted in the Prest-O-Lite company's becoming an enterprise of large magnitude, with plants in various States and distributing and service depots in every important centre in the country.

Up to 1905 the development of economical processes for obtaining oxygen had been almost entirely neglected; so, while the application of acetylene and oxygen to metal welding and cutting dates experimentally from 1901 and industrially from 1903, the development of the processes was seriously retarded owing to the cost of oxygen and the difficulty of obtaining an adequate supply. In the early years of the industry the users of the process were largely dependent on their own limited facilities for the production of oxygen from chemicals. Consequently the oxy-acetylene industry was given a tremendous impulse when, in 1907, a liquid air oxygen plant was put into operation in this country. It is a well-known fact that oxygen produced by the liquid air process is of the highest purity. This was the first unit of what has since become the great system of oxygen plants developed by the Linde Air Products Company, who now maintain producing plants and warehouses in more than 50 of the large industrial centres. From that time on the production of both oxygen and acetylene increased amazingly, keeping pace with the rapidly expanding applications of oxy-acetylene welding and cutting. The now almost universal adoption of the processes is due to their speed and economy combined with the characteristic excellence of oxywelding and cutting that is attained by the competent operator using standard equipment. See LIQUEFIED AND COMPRESSED GASES—ACETYLENE.

**WELDON, Richard Chapman**, Canadian legislator and educator: b. Sussex, New Brunswick, 19 Jan. 1849. He was graduated at Mount Allison University in 1866; took his Ph.D. at Yale University in 1872; later studied at the University of Heidelberg; and in 1884 was called to the bar of New Brunswick. He was professor of mathematics at Mount Allison University in 1875-83; and held the chair of constitutional law and was dean of the law faculty at Dalhousie University in 1883-1914. He served in the Dominion Parliament in 1887-96.

**WELDON, N. C.**, a town in Halifax County, on the Roanoke River and the Seaboard Air Line and Atlantic Coast Line railways, 97 miles east of Raleigh. It is at the head of steamboat navigation on the Roanoke. Here are located six churches, a State bank, a winery, several mills and a weekly newspaper. There is excellent water power and cotton mills, a corn mill, knitting mill, oil mill and machine shops have been established. The surrounding region is an agricultural one. Pop. 2,600.

**WELFARE WORK IN INDUSTRIES.** See INDUSTRIES, WELFARE WORK IN.

**WELL-TEMPERED CLAVIER** (from Ger. *Wohltemperirte Klavier*), the celebrated

collection of 48 preludes and fugue by J. Sebastian Bach, 1685-1750 (of the system of equal temperament). For this purpose he wrote a fugue in each key, the keys following another not in relation, but in chromatic ascent. (See MEANTO-TEMPERAMENT). Consult Grove, of Music and Musicians' (Vol. 1, 555, New York 1911).

**WELLAND**, Canada (formerly WILLE), town and county-seat of County, Ontario, on Welland Riv Welland Canal, 20 miles northwest N. Y., and on the Michigan Central Trunk, the Canadian Pacific and the quiete railroads. There are two docks, a turning basin and manu woolens and fencing material. The peat industry. Pop. 5,318.

**WELLAND CANAL**, Ontario ship canal extending from Port of Port Dalhousie, across the neck of of the Niagara River and Falls, taining continuous navigation bet Erie and Lake Ontario. See CANADI

**WELLDON, James Edward C** lish prelate and educator: b. Tonb 25 April 1854. He was educated at was head master of Dulwich Col of Harrow School, 1885-98. In t... year he was appointed to the bisho cutta, and as such was metropolita He resigned in 1902 and returned where he was made canon of Westr sides standard translations of Arist tics,' 'Rhetoric' and 'Nicomache he has published 'Sermons Preach row Boys' (1887); 'The Spiritua Other Sermons' (1888); 'The Hope tality' (1898); 'The Revelation o Spirit' (1902); 'The Gospel in a (1910); 'The Religious Aspects of I ment and Disendowment' (1911); tions and Reflections' (1915).

**WELLE-MAKWA**, wél'lé-māk Africa, the most important afflu Ubangi (q.v.), a tributary of the source is on the western slope of Pasha, and after a course of abou through a fertile and rich country t and east of the Kongo, it flows into at Dayu, opposite Yakoma, at the two other headstreams. The it Welle-Makwa was uncertain for explorers thought it was a differ the Ubangi, but their connection w tablished in 1888, and the river thr entire length of 1,500 miles is some the Welle-Makwa.

**WELLER, Reginald Heber**, Protestant Episcopal bishop: b. Jeff Mo., 6 Nov. 1857. He studied at of the South 1875-77, and was grad the Nashotah Theological Seminary, in 1884. Ordained to the priesthood named year he was rector of I Wis., 1884-88; of Waukesha, V 90 and of Stevens Point, Wis.. He was consecrated bishop of Fond du Lac 8 Nov. 1900, t spectacular ceremonial practised on

sion calling forth more or less criticism; and succeeded as bishop 30 Aug. 1912.

**WELLES**, wēlz, Gideon, American statesman: b. Glastonbury, Conn., 1 July 1802, d. Hartford, Conn., 11 Feb. 1878. He studied at Norwich University, Vermont, but did not complete the course there, and for a time turned his attention to the study of law. In 1826, however, he entered journalism as editor of the *Hartford Times*, which under his management became one of the leading Democratic papers of the State. He was one of the first publicly to advocate Andrew Jackson's election to the Presidency, and always warmly supported him. In 1827-35 he was a member of the Connecticut legislature, and both as legislator and editor advocated the abolition of imprisonment for debt, opposed the practice of special legislation and succeeded in obtaining the passage of general laws for the incorporation of business corporations. In 1836 he resigned the editorship of the *Times*, but continued to write for that paper. In 1835, 1842 and 1843 he was chosen State comptroller; in 1836-41 he was postmaster of Hartford; and in 1846 was appointed chief of the bureau of provisions and clothing in the Navy Department, which office he held till 1849. He had always been opposed to the extension of slave territory, and on the organization of the Republican party in 1855 became identified with it, and was Republican candidate for governor of Connecticut in 1856; and a member of the national committee. In 1861 he was appointed Secretary of the Navy, and conducted the affairs of his department with marked executive ability throughout the Civil War; he continued in office under President Johnson till 1869. He was later affiliated with the Liberal Republicans, and in 1876 was a supporter of Tilden. He wrote 'Lincoln and Seward' (1874). Consult 'Diary of Gideon Welles' (New York 1911).

**WELLESLEY**, wēlz'li, Arthur. See WELLINGTON, ARTHUR WELLESLEY, DUKE OF.

**WELLESLEY**, Richard Colley, Viscount AND MARQUIS, British statesman: b. Dublin, 20 June 1760; d. London, 26 Sept. 1842. He was educated at Oxford, and on his majority took his seat as Earl of Mornington in the Irish House of Peers. Three years after he was returned to the British House of Commons as member for Beeralston, and afterward sat for Windsor (1787-96), and for Old Sarum (1796-97). He was appointed governor-general of India in 1797, and in 1799 created Marquis Wellesley in the Irish peerage. His administration was notable, both for its ability and the large accessions of territory made under it by the conquest of Mysore and the humbling of the Marhattas. In 1809 he became Foreign Secretary under Mr. Perceval. In 1812 he resigned his place chiefly because he was in favor of Catholic emancipation, and did not return to office till 1821, when he became lord-lieutenant of Ireland. This post he retained till 1825, when he was removed from it by his brother, the Duke of Wellington, who was an opponent of emancipation and had become Prime Minister. In the Grey ministry he held the office of lord-steward till 1833, when he again became lord-lieutenant of Ireland. Displaced in the following year by the Peel ministry, he after-

ward held the office of lord-chamberlain for a few months of 1835. Consult Martin, 'Indian Despatches, Minutes, and Correspondence of the Marquis Wellesley' (1836-37), and biographies by Torrens (1880), Malleson (1889) and Hutton (1893).

**WELLESLEY**, Mass., town in Norfolk County, on the Boston and Albany Railroad, 14 miles west of Boston. It was incorporated as a town in 1881, and includes the villages of Wellesley, Wellesley Hills and Wellesley Farms. It is principally a residential town, with many broad streets and handsome residences. It is the seat of Wellesley College (q.v.), and also of Dana Hall, a secondary school for girls; Wellesley School and Rock Ridge Hall, secondary schools for boys; and two Roman Catholic academies, the Academy of the Assumption for girls and Saint Joseph's Academy for boys. There is also a public high school at Wellesley Hills, founded in 1865, and a public library of about 20,000 volumes. There is a weekly newspaper and three college publications. The government is vested in the town-meeting and the selectmen, chosen annually. The waterworks are owned and operated by the town. Pop. 6,439.

**WELLESLEY COLLEGE**, a college for women located at Wellesley, Mass. It was founded by Henry F. Durant to give "to young women opportunities for education equivalent to those usually provided in colleges for young men." The charter was obtained in 1870, and the college first opened to students in 1875. It is non-sectarian in control; three representatives of the alumnae serve on the board of trustees. In 1894 the system of elective courses was established which with some recent modifications is still in force. The college confers one baccalaureate degree, A.B., and the graduate degree, A.M. Certain courses are required in mathematics, philosophy, hygiene, Bible history, English, some foreign languages and natural sciences; in addition to the required studies every candidate for the degree must take a sufficient amount of elective work to complete the equivalent of 59 one-hour courses, a one-hour course being a course given once a week for one year. Of these electives 18 one-hour courses must be taken in one of the following ways: 9 in each of two subjects, related or unrelated; 12 in one subject with six in a tributary subject. Pedagogical courses are offered in the history and science of education and in methods of teaching; art and music are included in the curriculum; the courses in history and theory in both departments count toward the degree; studio work in art counts toward the degree after one course in history is completed; the regular practical work in music does not count toward a degree. A full course in music leading to the certificate of the department may be taken by candidates for the A.B. degree who remain at the college five years. The college contributes toward the support of the American School of Classical Studies in Athens, the American School of Classical Studies in Rome, the Marine Biological Laboratory at Wood's Holl and the women's table at the Zoological Station at Naples. There are 61 scholarships for undergraduates and one graduate fellow-

ship. The students maintain literary and dramatic societies. The campus has a particularly beautiful situation within the limits of the town; it includes a lake which affords excellent opportunity for rowing and skating; on this lake is held the annual "Float." The buildings include the Farmsworth Art Building, Whitin Observatory, Houghton Memorial Chapel Library, Billings Hall for Music, Mary Hemenway Hall for Physical Training, a President's House, Simpson Infirmary, Page Memorial Kindergarten, Guest House and 16 halls of residence; also temporary buildings for administrative, lecture and laboratory purposes, pending the completion of a liberal arts building now under construction and other members of proposed academic group. Productive funds equal \$2,783,969.83; special building and equipment funds, \$953,677.84. The library contains 87,000 volumes, including the Gertrude Memorial Library, the Library of American Linguistics and other special and departmental libraries. The students in 1918 numbered 1,600 and the faculty 137; about 42 per cent of the graduates have become teachers.

**WELLESLEY ISLANDS**, Australia, in Gulf of Carpentaria, are politically attached to Queensland. Mornington, the northernmost and largest island, is 40 miles long by 15 miles broad.

**WELLHAUSEN**, vèl'how-zèn, Julius, German Orientalist and Biblical scholar: b. Hameln, Hanover, 17 May 1844. He studied theology in the University of Göttingen, in 1872 was appointed professor of theology in Greifswald University, but resigned in 1882 because he could no longer hold the accepted views of Scriptural inspiration. He went to Halle as extraordinary professor of Oriental languages and in 1885 was appointed to an ordinary professorship at Marburg, whence in 1892 he removed to Göttingen to occupy a similar post. In 1871 he published a text-critical work on the books of Samuel, and in 1874 appeared his treatise 'Die Pharisäer und die Sadducäer.' The first volume of a 'Geschichte Israels' was issued in 1878 and a second edition of it in 1883, under the title, 'Prolegomena zur Geschichte Israels' (5th ed., 1899). The 'Prolegomena' was translated into English in 1885 by Black and Menzies, with a preface by W. Robertson Smith, the volume containing also a reprint of his article 'Israel' contributed to the 'Encyclopædia Britannica' (9th edition). The last-mentioned article was published separately in 1881 as a 'Sketch of the History of Israel and Judah' (3d ed., 1891), and included in a German form, as an 'Abriss der Geschichte Israels und Judas,' in the 1st volume of his 'Skizzen und Vorarbeiten' (1884-92). The 'Abriss' was amplified to form a work on 'Israelitische und Jüdische Geschichte' (1894; 4th ed. 1901). His masterly treatise on 'Die Composition des Hexateuchs und der Historischen Bücher des Alten Testaments' (1885; 3d ed. 1899) originally appeared in the 'Jahrbücher für Deutsche Theologie' (1876-77). Later works are 'Muhammed in Medina' (1882); 'Der Arabische Josippus' (1897); 'Reste Arabischen Heidentums' (2d ed. 1897), first published in the 'Skizzen und Vorarbeiten'; 'Die Kleinen Propheten über-

setzt, mit Noten' (1892; 3d ed. 1898) ferent books on the evangelists ('Mark' 'Matthew' (1904); 'Luke' (1904); (1908); and 'Einleitung in die drei Evangelien' (1905); 2d ed. 1911).

**WELLING**, James Clarke, American actor: b. Trenton, N. J., 14 July 1825; d. Ford, Conn., 4 Sept. 1894. He was graduated from Princeton in 1844, was appointed principal in the New York Collegiate School in 1848 and in 1856-65 was literary editor of Washington *National Intelligencer*. He clerk of the United States Court of Appeals in 1862-67, in 1867-70 was president of Johns College, Annapolis, Md.; occupied chair of belles-lettres at Princeton in 1871 and in 1871-94 was president of Columbia University, Washington, D. C. He regent of the Smithsonian Institution, president of the Corcoran Gallery of Art and of the Philosophical and the Anthropological Societies of Washington.

**WELLINGTON**, Arthur Melliss, American civil engineer: b. Waltham, Mass., Dec. 1847; d. New York, 16 May 1907. His defective eyesight prevented his entering university but he studied civil engineering under Prof. J. B. Henck in Boston. He was associated with the laying out of Park Park, Brooklyn, and from 1868 was a railway engineer. In 1881-84 he was chief engineer of the Mexican National and the Mexican Central railroads. He was the author of a system for multiplying the traffic facilities of a bridge by five times, recommended to the Board of Experts in 1887. In 1884-87 he was editor of the *Railroad Gazette*; and in 1887 until his death he was one of the editors and owners of the *Engineering News*. He was also active as a consulting engineer in important public works, among them the design for the Boston Subway and the abolition of grade crossings in Buffalo. Author of 'Diagrams of Railway Works' (1878); 'Field Work of a Railway Location and Laying out of Works' (1887).

**WELLINGTON**, Arthur Wellesley, British soldier and statesman: b. 1. Walmer Castle, England, 14 Sept. 1759. He was the fourth son of the 1st Earl of Wellington. His mother was the eldest daughter of the 1st Viscount Dungannon. He was educated at Eton, privately at Brussels, and at the Military College of Angers. On 7 July 1787 he received a commission as ensign in the 73d Foot. He was gazetted under the name of Wesley, the family name till changed by his brother to Wellesley. After a series of changes and promotions he was promoted by purchase in September 1793 to the rank of lieutenant-colonel of the 33d regiment, which he had attained his majority in the same year. In 1790 he was returned to the Irish Parliament for the family borough of Trim, in the county of Meath. In May 1796 he sailed with his regiment for France to join the army of the Duke of York. He joined his regiment at the Cape, arriving in Calcutta in February 1797, and was attached to the Bengal service. Later the 33d regiment was attached to the Nizam's contingent in Deccan with Wellesley in command. The

entered Mysore in March 1799. An engagement took place at Mallavelly on the 27th, in which Wellesley, who commanded the left wing, turned the right of the enemy. He was subsequently employed to dislodge the enemy from their posts in front of Seringapatam and after the capture of that capital was appointed July 1799, to its command. During his administration he was compelled to take up arms against Dhundiah Waugh, a robber chief, who styled himself "King of the Two Worlds." Wellesley overtook and routed him with a small body of cavalry 10 Sept. 1800. In April 1802 Wellesley attained the rank of major-general. Early in 1803 he was appointed to the command of a force destined to restore the Peishwa of the Mahrattas, driven from his capital by Holkar. This operation successfully performed, the other Mahratta chiefs, Scindia and the Raja of Berar, showed hostile designs against the British and Wellesley was appointed to the chief military and political command in the operations against them. After an active campaign, in which he took Ahmednagar and Arungabad, he encountered a powerful Mahratta army, assisted by French officers, at Assaye (23 September) and entirely defeated it. The parallel successes of General Lake, and the defeat of the Raja of Berar by Wellesley at Argaum on 29 November, compelled the submission of the Mahrattas and peace was restored on conditions drawn up by the successful general. The fame of Wellesley's achievements had now spread over India. Before leaving Madras he received his appointment as K.C.B., and the thanks of both houses of Parliament. He sailed for England on 10 March 1805 and arrived in September.

On 10 April 1806 Wellesley married Lady Catherine Pakenham, third daughter of the Earl of Longford. He had previously been elected and distinguished himself in the House of Commons by the defense of his brother's administration in India. In April 1807 he was appointed chief secretary for Ireland and in August received the command of the reserve in the expedition to Copenhagen under Lord Cathcart and Admiral Gambier. He took Kioge 29 April, the only land operation of importance. On returning he resumed his duties as secretary and received the thanks of Parliament for his share in the expedition. On 25 April 1808 he attained the rank of lieutenant-general.

In June, Wellesley received the command of a force destined to operate in the north of Spain and Portugal in aid of the revolt against Napoleon. On 30 July he anchored in Mondego Bay, and landed his troops at Figueira. The English began their southward march on 8 August. Wellesley moved on the coast road to Torres Vedras. At Roliça he encountered about 5,000 men under Delaborde, whom Junot had sent in advance to arrest his progress. This corps, after a spirited resistance, was driven back and retired to Torres Vedras. Wellesley now drew nearer the coast, reaching Vimeiro on the 19th, where he was reinforced by two brigades from England, raising his force to 17,000. At the same time he was superseded in the command. The government had determined to increase their

army in the Peninsula, and had appointed Sir Hew Dalrymple to the chief command, with Sir Harry Burrard as second and Wellesley, Moore, Hope, Paget and Fraser as divisional commanders. Junot determined to attack the English on the land side while they were in the immediate neighborhood of the sea. The attack was made on 21 August and Junot was beaten. After the battle Junot proposed an armistice, the result of which was the famous Convention of Cintra, by which the French agreed to evacuate Portugal on condition of being conveyed to France with their arms and baggage. Public feeling in England over the excessive liberality of the terms ran so high that the generals were recalled to be examined by a board of inquiry, but their conduct was approved of and commended. Wellesley proceeded to Ireland in December as chief secretary, and early in 1809 received the thanks of both houses of Parliament for his conduct of the campaign.

In the latter part of 1808 Napoleon overran Spain with 200,000 men, and Sir John Moore, pursued by Soult, carried the British army to Coruña, where it embarked for England. Lisbon was still held by Sir John Cradock and a British force occupied Cadiz, when Wellesley was appointed to assume the chief command in the Peninsula. He arrived at Lisbon 22 April 1809. He advanced against Soult at Oporto and the French were thrown into confusion and retreated precipitately. Soult now retired to Galicia, followed by Wellesley to the frontiers of Portugal and harassed by the insurgent Portuguese. The Peninsula was at this time occupied by about 250,000 French troops; but after the departure of Napoleon the independence or insubordination of the French marshals prevented effective co-operation of the different armies, and the French command never extended beyond the districts occupied by their armies. The British commander had a series of difficulties to contend with. First was the smallness of the armies on which he could rely. The numbers of the British were always comparatively insignificant and reinforcements were slowly and scantily supplied. Almost as formidable was the difficulty of co-operating with his allies. Spain and Portugal were without regular governments. The Portuguese officers had mostly fled to Brazil, but the Portuguese troops, carefully drilled by Beresford and placed under the command of British officers, soon became a tractable and efficient force. It was far otherwise with the Spaniards. The junta and the generals were alike ignorant, incompetent and self-conceited and with the raw levies which constituted the Spanish armies it was positively dangerous to co-operate. Even with the Portuguese government, Wellington (as he must now be called) had natural but formidable difficulties to contend with. The subsistence of the armies was a constant source of danger and embarrassment both in Spain and Portugal. The resources of the country were oppressed by the armies of three nations. The French took all they wanted and wasted much more. The Spanish armies, numerous and inefficient, were a sufficient weight for the junta, which always supplied with reluctance the wants of the British who had commonly much greater

difficulty in procuring provisions for money than either of the other armies had in seizing them. Through all these difficulties Wellington adhered with undeviating patience and constancy to the strict principles of discipline he had laid down. He remonstrated with herculean labor, and with admirable spirit, as his dispatches show, with authorities of all kinds; but he never under the great temptation took, or suffered others to take, violent means to supply his most pressing wants.

By a misunderstanding between Soult, who held the command in the north of Spain, and Ney, who was under him, Galicia was evacuated by both marshals and never afterward recovered, a valuable result of Wellesley's first campaign. To co-operate with the Spanish armies, Wellesley had determined to advance into Spain, which he did in July by the north of the Tagus. Nearly every important fortress in Spain was in the hands of the French.

The victory of Talavera, 27-28 July, earned Wellesley the titles of Baron Donro and Viscount Wellington. Next day the French retreated across the Alberche and broke up their army. The first invasion of Spain had resulted in nothing but a series of movements among the French troops. Wellington at this time surveyed the lines of Torres Vedras and formed his plan of fortifications for their defense. Anticipating that invasion would come from the north, he left General Hill to guard the Tagus and fixed his headquarters at Viseu.

The French in the meantime were largely reinforced. Soult was in Andalusia with 60,000 men threatening the south of Portugal, while in the north the army of Portugal was concentrating to the extent of 70,000 to 80,000, and the veteran Masséna was appointed to command it. Wellington was able to bring into the field from 50,000 to 60,000 British and Portuguese troops. The French invested the Spanish fortress of Ciudad Rodrigo early in June and took it on 10 July. They then advanced to the Coa, from which the British retired. Almeida was captured on 27 August. Wellington fell back on the valley of the Mondego. In the middle of September, Masséna began his march down the right bank of the river. At the Sierra de Busaco, a high ridge in front of Coimbra, Wellington made a stand and repulsed the French. After the battle, Masséna turned Wellington's position, who retreated to Leiria, where he halted two days. On 8 October he entered his lines, just as the autumnal rains were beginning to fall. A powerful fleet and a flotilla of gunboats on the Tagus contributed to their defense. Masséna was wholly unprepared for his reception and after some vain demonstrations he retired from their front. The Portuguese parties had cut off his communications with Spain and sickness was rapidly diminishing his numbers. On 15 November he fell back to Santarém.

Napoleon recommended to waste the English with continual engagements of advanced guards and sent Soult instructions to co-operate with Masséna. But Soult, with the blockade of Cadiz and with the Spaniards on his hands, could only spare a sufficient force to besiege Badajoz. In March 1811 Masséna was compelled to begin his retreat, which he conducted with great skill. The French crossed the Agueda on 6 April. Wellington estimated their

loss in the campaign at not less than Wellington blockaded Almeida and can his army between the Coa and the Agueda turned to Badajoz, which had been Soult and invested by Beresford. He speedily recalled by an aggressive movement of Masséna to relieve Almeida. Wellington took up a position to cover the fort of Fuentes de Onoro, where he was at Masséna with a superior force. In the meantime he performed the exceedingly critical operation of changing his front in presence of the French. The maneuver was successful and Masséna was repulsed. Almeida surrendered a few days after the battle and Masséna was also at the same time superseded by Marmont. So the meantime had been defeated by Beresford at Albuera in an attempt to relieve Badajoz. Wellington returned to prosecute the siege of Ciudad Rodrigo. Marmont also moved south to join Soult, afterward returned to Salamanca. This Wellington pushed the siege of Ciudad Rodrigo in preference to that of Badajoz and then turned to the Agueda. Marmont, however, advanced with a superior force and he went to the Coa. Marmont returned to Salamanca.

During the winter Wellington continued to occupy himself with preparations for this collecting his stores at Almeida under the command of repairing it. On 6 Jan. 1812, he moved his headquarters to Gallegos, invested Ciudad Rodrigo on the 8th and took it by assault on the 12th. An earldom, a pension and a dukedom awarded this achievement. Wellington now went south with his principal force to take Badajoz; and Marmont, who had collected his forces to raise the siege of Ciudad Rodrigo, invaded Portugal by Sabugal and ravaged the country. Badajoz was taken on 6 April, after a heavy loss. Having secured the frontier, Wellington determined again to advance into Spain. Leaving Hill on the southern flank, he moved north with his main army and on 17 June reached Salamanca. Marmont retreated to Toro. The French general, when he concentrated his forces, attempted by a series of pretentious manœuvres to surprise the British commander, his ultimate object being to cut off from his communications. With this purpose in view he crossed the Tormes, followed by Wellington, who took up his position between the river and two hills called the Arapiles. Marmont's overdisplay of tactics recoiled on himself. Having gained the outer Arapiles, he extended his left to attack the British. Wellington gave him the opportunity he had desired of attacking him. Marmont was wounded and the French left and centre broken. Clausel, who attempted to re-form the French, was routed. Numerous prisoners were taken by the cavalry in pursuit and the French retreated to Burgos. Wellington reached Valladolid on 31 July and turning on Joseph, who had advanced to support Marmont, followed him to Madrid, which he entered on 12 August. Napoleon was now advancing to join Wellington. Joseph fell back from Toledo to Almadén and Murcia. These successes compelled Soult to abandon Andalusia and an Anglo-Spanish army from Cadiz took Seville. Wellington's movement was against the army he had sent under Clausel, which had been defeated at the battle of Barrosa. He left Hill in Madrid (1811) and advanced to Burgos, being joined by

way by a body of Spaniards. The French retired, leaving a garrison in the castle, which Wellington deemed it necessary to take before advancing. The siege, for want of proper artillery, occupied him till 21 October. In the meantime the northern army under Souham was again advancing and Soult with a powerful army marching on Madrid, which Hill had abandoned to fall back on Salamanca. Wellington abandoned the siege and retreated, closely followed by the French, who repeatedly attacked his rear. At Palencia he was joined by a brigade from England. At Tudela, Souham halted to wait for Soult and Wellington proceeded to the Tormes, where he was joined by Hill, and when the French crossed the Tormes in force he took up his old position at the Arapiles. The united armies of Soult and Souham amounted to nearly 90,000 men. Wellington's strength was over 50,000. The enemy, instead of attacking, threatened his communications, upon which he retreated to the Agueda and established his headquarters at Ciudad Rodrigo. The French, not being prepared to invade Portugal, withdrew their armies to cantonments in Castile. General Hill's corps continued to occupy Estremadura and the rest of the British were cantoned on the Portuguese frontier.

The gains of this campaign were substantial. The French had not only been compelled to reinforce their Spanish armies largely at the expense of their operations elsewhere, but had lost Andalusia and given the British a footing in Estremadura. Wellington received (18 August) the title of marquis and Parliament voted him thanks and £100,000. The failure of the Russian campaign compelled Napoleon to recall Soult from Spain and Wellington was able to open the campaign of 1813 with a force of 70,000 British and Portuguese. He had also been appointed commander-in-chief of the Spanish armies. He opened the campaign in May by an advance in the former direction and on 12 June reached Burgos, the French retreating to the Ebro. Wellington turned their position by crossing the Ebro near its source and after some unsuccessful fighting they fell back on Vittoria. In a strong position commanding the principal roads through the town they were defeated by the British on 21 June. Being driven from the town, while the British left had seized the Bayonne road, by which they retreated, they were thrown into confusion and routed. Wellington now occupied the passes of the Pyrenees and besieged Pampeluna and San Sebastian. He was created field-marshal and received the Spanish title of Duke of Vittoria. Soult was dispatched by Napoleon, with the title of lieutenant of the emperor, to restore matters in the Peninsula. He had still a powerful army (80,000), but after a series of engagements, called the battles of the Pyrenees, he retreated into France. Some time being spent in pushing the sieges of Pampeluna and San Sebastian, the former of which surrendered 31 August, the latter 31 October, Wellington crossed the Bidassoa in October and in November the whole army descended from the Pyrenees into the French plains. Some severe fighting occurred before the armies went into winter cantonments. On 27 February Wellington defeated Soult at Orthez and the French retreated to Toulouse. Suchet had abandoned Catalonia and reached Narbonne. Another en-

agement took place in front of Toulouse on 10 April, in which the French after severe fighting were driven into the town. Next day, Soult evacuated Toulouse and Wellington entered it on the 12th. In the afternoon news arrived of Napoleon's abdication, but Soult declined to submit to the provisional government without further advice and Wellington refused an armistice. Advices having arrived from Berthier, Soult entered into a convention on 18 and Suchet on 19 April. In a sortie of the garrison of Bayonne, before the peace was known, the British suffered severely. On 30 April Wellington, leaving his army in quarters, set out for Paris. In May he had to visit Madrid to allay political differences among the Spanish generals and on 14 June he issued farewell orders to his army. He was created Marquis of Douro and Duke of Wellington in May, with an annuity of £13,000, commutable for £300,000, afterward £400,000. He received the thanks of both houses of Parliament. In July he went as Ambassador to France and he succeeded Lord Castlereagh as British representative in the Congress of Vienna. In April he took the command of the army assembled in the Netherlands to oppose Napoleon. (See FRANCE; NAPOLEON I; WATERLOO). On his return to England after the restoration of peace he received a vote of £200,000 for the purchase of the estate of Strathfieldsaye, to be held on presenting a colored flag at Windsor on 18 June each year. Numerous foreign honors were showered upon him; among others he was made field-marshal of the armies of France, Russia, Austria and Prussia.

With the return of peace he resumed the career of politics. He accepted the post of Master-General of the Ordnance with a seat in the Cabinet of Lord Liverpool in January 1819. In 1822 he represented Great Britain in the Congress of Vienna. In 1826 he was appointed high-constable of the Tower and went to Saint Petersburg as Ambassador on the affairs of Greece. On 22 Jan. 1827 he succeeded the Duke of York as commander-in-chief of the forces. On the accession of Canning to office (April 1828) he set the bad example of resigning this post on political grounds. He resumed it again on the accession of Lord Goderich. On 8 Jan. 1828 he accepted the premiership and, resigning the command of the forces, gave it to Lord Hill. During his first year of office he carried the repeal of the Test and Corporation Acts. In January 1829 he was appointed governor of Dover Castle and lord warden of the Cinque Ports. This year he carried the Catholic Emancipation Bill. Both this and the repeal of tests were reforms which he had steadfastly opposed and which he yielded to necessity rather than conviction. He fought a duel in defense of his conduct on this bill with Lord Winchilsea on 21 March. In 1830 repeated motions for parliamentary reform were defeated, but the growing discontent throughout the country on this subject and a defeat in Parliament caused the resignation of the government in November. His opposition to reform made the duke so unpopular that he was assaulted by a mob on 18 June 1832 and his life endangered. He accepted the office of Foreign Secretary under Sir Robert Peel, 9 Dec. 1834, and retired with him, 8 April 1835. In the Peel ministry in 1841 he took a seat in the Cabinet without office. On 10 Dec. 1842, on the death of Lord Hill, he resumed the

command of the forces, which he held till his death. On the return of Peel to office in 1846 he supported him in carrying the repeal of the corn-laws, which up till then he had opposed. From this time his general policy in Parliament was to support the government of the day.

**Bibliography.**—'Wellington's Despatches, 1779-1815,' edited by Colonel Gurwood (1834-39); 'Supplementary Despatches and Memoranda, 1794-1818,' edited by Wellington's son (1858-72); 'Civil and Political Despatches, 1819-32,' edited by Wellington's son (1869-80); 'Speeches in Parliament,' edited by Gurwood (1854); the 'Lives' by Brialmont (1856-57); Gleig (1858-60); Hamley (1860); Browne (1888), composed of extracts from the records; Hooper (1889); Maxwell (1899); and those of Wright and Yonge. W., 'Wellington's Campaigns' (London 1908); Fitchett, W. H., 'The Great Duke' (New York 1912). See also INDIA; PENINSULAR WAR; SPAIN.

**WELLINGTON,** Chile, an island off the west coast of Magallanes Territory, 138 miles long and 35 miles wide. Its northernmost extremity is Cape San Roman.

**WELLINGTON,** Kan., city and county-seat of Sumner County, situated in the south central part of the State, near the southern boundary, on Slate Creek and on the Atchison, Topeka and Santa Fé, the Southern Kansas and the Chicago, Rock Island and Pacific railroads. It was first settled in 1871; and became a city of the third class in 1876 and a city of the second class in 1880. It is situated in an agricultural region and carries on an important export trade in grain and other agricultural products; it contains grain elevators, three flouring mills, plow works, an ice factory and the shops of the Atchison, Topeka and Santa Fé Railroad. There are three banks and a daily and three weekly newspapers. It is the seat of the Sumner County High School. The city government is vested in a mayor and a council of 10 members, half of whom are elected each year; the city owns the waterworks and the electric-light plant. Pop. 5,642.

**WELLINGTON,** New Zealand, (1) The capital city of New Zealand and also the provincial district of Wellington, situated on Lambton Harbor, on the southwest of Port Nicholson, an inlet of Cook Strait, about 1,200 miles southeast of Sydney in Australia. Its fine harbor is the safest and most commodious in New Zealand. It receives most of the direct sea trade of New Zealand. The principal buildings and institutions are government house, a fine building in Italian style, said to be the largest wooden structure in the Southern Hemisphere; the houses of legislature (the parliamentary library building was destroyed by fire 10 Dec. 1907); the government building; Supreme Court edifice; Anglican, Roman Catholic, Wesleyan, Primitive Methodist, Presbyterian, Congregational and other churches; a free public library; Wellington College, a girls' high school, Saint Patrick's College (R.C.), a technical school and other similar educational institutions; Victoria University College, affil-

ated to the University of New Zealand; a general hospital; a lunatic asylum; the Boys' Institute; and the botanical gardens. The city is lighted by electricity and has a good water supply and its streets are traversed by electric tramways. The chief industrial establishments are tanneries, candle and soap works, coffee-mills, boot factories, biscuit works, foundries, brick-works, saw-mills, woolen-mills, breweries and meat-packing establishments. The town has a harbor that has been improved and fortified. Unlike most New Zealand towns, this one is built of wood, owing to the volcanic nature of its site, where several earthquakes have already occurred. The foreign trade increases steadily, being double in 1912 the figure of 1908 and nearly 70 per cent greater in 1916 than in 1912. The 1916 total was \$84,000,000. The population has grown from 69,000 in 1909 to 97,000 in 1919.

(2) A provincial district in the south of North Island; area, 10,807 square miles. Its coast is but little indented, the principal openings being Palliser Bay and Port Nicholson in the south. It is traversed throughout almost its whole length by a range of mountains, averaging about 4,000 feet in height. Parallel to this main range and nearer the east coast there is a series of lower ranges and between these two chief mountain systems extends the broad Wairarapa Plain, merging northward into an undulating country. A considerable extent of fairly level country, increasing in breadth northward, is also found along the west coast. The district is well-watered by several rivers and in the south are Lakes Wairarapa and Onoke. Wellington is well-wooded and timber is one of its chief exports. Much of the surface is admirably adapted for pastoral purposes and there are in the district several million sheep, in addition to large numbers of cattle and horses. Agriculture is also successfully carried on in several parts, the principal crops being oats, wheat, potatoes and turnips. The number of cheese and butter factories is steadily increasing. Little mineral wealth has been found in the district of Wellington, but some gold has been worked. Railways run from Wellington to Napier and New Plymouth. Pop. 232,114.

**WELLINGTON,** Ohio, village in Lorain County, on the Wheeling and Lake Erie, the Cleveland, Cincinnati, Chicago and Saint Louis and other railroads, about 35 miles southwest of Cleveland. It is the commercial centre of a farm and dairy section. It is noted for its large annual shipments of cheese. It has flour mills, lumber mills, a foundry and in the vicinity are a number of butter and cheese factories. There are two banks and a newspaper. Pop. about 2,131.

**WELLMAN,** Walter, American journalist and explorer: b. Mentor, Ohio, 3 Nov. 1858. He obtained a secondary education in Michigan in 1879, established the *Evening Post* of Cincinnati and from 1884 was political and Washington correspondent of the *Chicago Herald* and *Record-Herald*. In 1892, after investigation of the subject, he located the landing place of Columbus in the New World on Watling Island (San Salvador) in the Bahamas and built a monument on the spot as he had determined it. He led an expedition to the Arctic regions in 1894, reaching lat. 81°, northeast of Spitzbergen, and in 1898-99 a second expedition,

reaching lat. 82° and discovering many islands. He wintered in Franz Josef Land and in the spring of 1899 made an unsuccessful dash for the pole. In May 1899, a party directed by E. B. Baldwin (q.v.), a member of the expedition, discovered Graham Bell Land. In 1910 he undertook to cross the Atlantic Ocean in a balloon, starting from Atlantic City, N. J. A long sausage-like sea-anchor was trailed from the balloon to the water but proved an unsatisfactory device. After traveling 1,010 miles and breaking what was then the world's record, Wellman and his companions were picked up by the steamship *Trent*, 375 miles east of Cape Hatteras. His writings include an exposé of Dr. Cook's claim to polar discovery and many magazine articles.

**WELLS, Amos Russel**, American editor and author: b. 23 Dec. 1862 at Glens Falls, N. Y. He graduated at Antioch College in 1883. He was professor of Greek and geology at Antioch College 1883-91 and from 1891 editor of the *Christian Endeavor World*, Boston. From 1901 he was associate author of 'Peloubet's Notes on the Sunday School Lessons.' He is a member of the International Sunday-School Lesson Committee. He is a voluminous author, no less than 63 titles being credited to his pen. They include books dealing with young people's work, the Sunday school, juvenile fiction, poetry and devotional literature.

**WELLS, Benjamin Willis**, American journalist and author: b. Walpole, Cheshire County, N. H., 31 Jan. 1856. He was graduated from Harvard in 1877, studied also at Berlin, was a Fellow of the Johns Hopkins University, in 1891-98 he was professor of modern languages in the University of the South (Sewanee, Franklin County, Tenn.) and from 1899 to 1912 he was a member of the staff of *The Churchman* (New York). His chief publications are 'Modern German Literature' (1895); 'Modern French Literature' (1897); and 'A Century of French Fiction' (1898), historical and critical studies. He also edited numerous German and French texts, contributed largely to encyclopedias and periodicals, and edited (with W. P. Trent) 'Colonial Prose and Poetry' (1902), an anthology.

**WELLS, Carolyn**, American humorous writer: b. Rahway, N. J., about 1873. She took up literary work in 1895, and her many publications, which are chiefly for juvenile readers, include 'At the Sign of the Sphinx' (1896); 'The Story of Betty' (1899); 'Folly in Fairyland' (1901); 'Eight Girls and a Dog' (1902); 'The Pete and Polly Stories' (1902); 'Rainy Day Diversions' (1907); 'The Clue' (1909); 'The Lovers' Baedeker' (1912); 'The Maxwell Mystery' (1913); 'Anybody but Anne' (1914); 'Bride of a Moment' (1916); 'Faulkner's Folly' (1917); 'The Room with the Tassels' (1918).

**WELLS, Charles Jeremiah**, English poet: b. probably London, about 1799; d. Marseilles, France, 17 Feb. 1879. He was a schoolfellow of a younger brother of the poet John Keats, and was the subject of a sonnet by the poet; later, however, he lost his friendship, as well as that of Haslitt. He wrote extensively but not successfully, and upon his wife's death he destroyed most of his work. He was for a

time a solicitor in London, but retired to Wales about 1830, removed to Hertfordshire in 1835, and after 1840 lived abroad. Of his work there remains a volume of prose 'Stories After Nature' (1822; reprinted 1891); and the Biblical drama, 'Joseph and His Brethren' (1824). The drama met with little favor until it came to the notice of Rossetti in 1863 and was warmly praised by him, a judgment later confirmed by Swinburne. It was reprinted in 1876 and brought a considerable meed of praise to the author in his last years.

**WELLS, David Ames**, American political economist: b. Springfield, Mass., 17 June 1828; d. Norwich, Conn., 5 Nov. 1898. He was graduated from Williams College in 1847, and from the Lawrence Scientific School in 1851, but before entering the latter institution had been assistant editor of the *Springfield Republican*, and was one of the promoters of the invention of a mechanism for folding books and newspapers in connection with the printing press. In 1851 he was appointed assistant professor at the Lawrence Scientific School, and was also lecturer on chemistry and physics at Groton Academy; during this earlier period of his life he published several textbooks on the natural sciences. He first attained reputation as a political economist by an address on 'Our Burden and Our Strength,' read before a literary society of Troy in 1864; it discussed the resources of the United States in regard to the nation's debt-paying ability, and attracted the attention of the President, who summoned him to a conference in regard to the national finances. This resulted in the creation of a commission of three for the investigation of questions of taxation and revenue, of which commission Wells was chairman. In this capacity he was the first to collect economic and financial statistics for government use. In 1866 he was appointed to the office of special commissioner of revenue, was instrumental in abolishing the many petty taxes which had been imposed during the war, and originated most of the important forms and methods of internal revenue taxation adopted from 1866 to 1870. In the latter year the office which he held was abolished. He had at first been an advocate of the protectionist policy, but after a visit to Europe and a careful study of the English system, he changed his views, and advocated the system of free trade. In 1876 he was an unsuccessful candidate for Congress on the Democratic ticket. He published 'Our Burden and Our Strength' (1864); 'The Creed of the Free Trader' (1875); 'Why We Trade and How We Trade' (1878); 'The Silver Question or the Dollar of the Fathers vs. the Dollar of the Sons' (1878); 'Our Merchant Marine; How it Rose, Increased, became Great, Declined and Decayed' (1882); 'A Primer of Tariff Reform' (1884); 'Practical Economics' (1885); 'Relation of Tariff to Wages' (1888); 'Recent Economic Changes' (1898). His writings are notable for their clear and forcible presentation of a vast number of details and statistics.

**WELLS, Frederic Lyman**, American psychiatrist: b. Boston, Mass., 22 April 1884. He was graduated at Columbia University in 1903 and took his Ph.D. there in 1906. He was connected with the faculty at Columbia University

in 1905-07 and in 1910-11; was assistant pathological psychologist at the McLean Hospital, Waverly, Mass., in 1907-10 and in 1911-17; and was connected with the Psychiatric Institute, Ward's Island, New York, in 1910-11. He was commissioned captain of the Signal Reserve Officers' Corps, 18 Sept. 1917, and was assigned to active service at Boston, 28 Sept. 1917. Author of 'Mental Adjustments' (1917).

**WELLS, Heber Manning**, American politician: b. Salt Lake City, 11 Aug. 1859. He was graduated from the University of Utah in 1875, and began early to take an active part in public life. He was recorder of Salt Lake City in 1882-90, and a member of the city board of public works in 1890 and in 1893. He was a member of the constitutional convention which framed the constitution under which Utah was admitted as a State; in 1895 was elected governor of Utah for a five years' term on the Republican ticket, and in 1900 was re-elected for a four years' term. During the prolonged struggle between the mine owners and miners' unions in 1904, he maintained an impartial attitude as far as possible, but firmly opposed anarchy and disorder. In 1905 he retired from politics and engaged in banking business.

**WELLS, Herbert George**, English author: b. Bromley, Kent, 21 Sept. 1866. He was educated at the Royal College of Science (South Kensington, London), published a 'Text-Book on Biology' (1892-3), and followed this by a series of works of fiction in which science and mechanics are employed for the accomplishment of various wonders narrated in the circumstantial and plausible manner of Verne. In his later years he was more versatile, and displayed a tendency to discuss mystic and social subjects in the form of fiction. He has made a place for himself in the very front rank of modern writers. Among them are 'The Time Machine' (1895); 'Select Conversations with an Uncle' (1895); 'The Wonderful Visit' (1895); 'The Island of Dr. Moreau' (1896); 'The Wheels of Chance' (1896); 'Thirty Strange Stories' (1897); 'The Invisible Man' (1897); 'The War of the Worlds' (1898); 'Tales of Space and Time' (1899); 'When the Sleeper Wakes' (1899); 'Love and Mr. Lewisham' (1900); 'Anticipations' (1901); 'The First Men in the Moon' (1901); 'Mankind in the Making' (1903); 'Twelve Stories and a Dream' (1903); 'The Food of the Gods' (1904); 'A Modern Utopia' (1905); 'Kipps' (1905); 'In the Days of the Comet' (1906); 'The Future in America' (1906); 'This Misery of Boots,' a tract in favor of Socialism (1907); 'New Worlds for Old,' an account of Socialism (1908); 'First and Last Things,' a confession of faith (1908); 'The War in the Air' (1908); 'Tone Bungay,' a novel of contemporary life (1909); 'Ann Veronica' (1909); 'The History of Mr. Polly' (1910); 'The New Machiavelli' (1911); 'Floor Games for Children' (1911); 'Marriage' (1912); 'Little Wars,' a floor game book (1913); 'The Passionate Friends' (1913); 'The Wife of Sir Isaac Harman' (1914); 'An Englishman looks at the World' (1914); 'The World Set Free' (1914); 'The War that will end War' (1914); and 'The Peace of the World' (1915), war pamphlets; 'Boon,' under the pseudonym Reginald Bliss

(1915); 'Bealby' (1915); 'The Research-nificent' (1915); 'What is Coming?' ('Mr. Britling Sees it Through' (1916); 'Elements of Reconstruction,' under the donym D. P. (1916); 'War and the Ft 'God, the Invisible King'; 'The Soul Bishop' (1917); 'The Idea of a League of Nations' (1919). His short stories were printed in a definitive collection under the title of 'The Country of the Blind' (1911). Many of his works have been translated into other languages.

**WELLS, Horace**, American dentist: b. Hartford, Vt., 21 Jan. 1815; d. New York, 24 Jan. 1848. He studied dentistry in New York and practised it there until 1836, then moved to Hartford, Conn. For years he made experiments and experiments in search of an agent for preventing pain in the extraction of teeth, and finally became convinced that he had discovered such an agent in nitrous-oxide gas. He made a practical test by having one of his own teeth extracted while he was under the influence of his supposed anæsthetic. The operation confirmed his belief in the discovery. Thenceforth he used nitrous-oxide gas in his practice. He published 'A History of the Application of Nitrous Oxide Gas, Ether, and Other Vapors to Surgical Operations' (1847). His claims to the discovery of anæsthetics were controverted in the interest of G. Q. C. T. Jackson, W. T. G. Morton and J. C. Warren (qq.v.), to each of whom some of the honors of its introduction belong. Wells had a predecessor in C. W. Long, but with regard to the first surgical use of anæsthetic, all other names must yield to his. He became mentally unbalanced in advocating his claims in New York, was committed to custody and committed suicide. A monument to Wells stands in Bushnell Park, Hartford, Conn. See ANÆSTHETICS.

**WELLS, Horace Lemuel**, American chemist: b. New Britain, Conn., 5 Oct. 1855. He was graduated at the Sheffield Scientific School, Yale, in 1877. He became a member of the faculty at Yale in 1884, and since 1894 has been professor of analytical chemistry and metallurgy there. He has made many original investigations in inorganic chemistry and was elected to the National Academy of Sciences in 1903. Author of 'Spectroscopy' (1901); 'The Chemical Laboratory of the Sheffield Scientific School' (1901); 'Chemical Calculations' (1903); 'Textbook of Chemical Analysis' (1905), etc.

**WELLS, Lemuel Henry**, American Episcopal bishop: b. Yonkers, N. Y., 1841. He was graduated from Hobart College in 1867, having during the Civil War served as a lieutenant in a Wisconsin regiment and being graduated from Berkeley Divinity School, Middletown, Conn., took priest's orders in the Episcopal Church in 1871. He was rector of Walla Walla, Wash., 1871-82; of Saint Paul, Tacoma, 1884-89, and of Trinity Temple, Spokane, 1890-92. In 1892 he was consecrated as bishop of Spokane.

**WELLS, Rolla**, American capitalist: b. Saint Louis, Mo., 1856. Entered mercantile business in the employ of a street-car way company and became assistant

tendent and finally general manager of the company. Giving up the latter position in 1883, he became prominently identified with a number of manufacturing and commercial corporations. He has been active in local politics as a Democrat; was a delegate to the Democratic National Convention in 1896 and served two terms as mayor of Saint Louis from 1901 to 1909. His administration was efficient and economical. He took an efficient part in the preparation for the Saint Louis Exposition of 1904.

**WELLS, Webster**, American mathematician: b. Boston, Mass., 4 Sept. 1851; d. 1916. He was graduated from the Massachusetts Institute of Technology in 1873, pursued special studies in civil engineering and from 1873 was engaged in teaching at the institute, attaining full professorship in 1893. He has written a series of mathematical textbooks, among which are 'Logarithms' (1878); 'Plane and Spherical Trigonometry' (1884); 'Higher Algebra' (1889); 'Complete Trigonometry' (1900); 'Text Book of Algebra' (1906), etc.

**WELLS, William Charles**, British physician: b. Charleston, S. C., 24 May 1757; d. London, England, 18 Sept. 1817. He was the son of a Scottish printer who settled in South Carolina in 1753. He was graduated M.D., at Edinburgh University in 1780, and in 1781 he returned to America to look after his father's property. He supported the cause of the British and for a time after 1782 he published a weekly newspaper at Saint Augustine, Fla. In 1784 he engaged in practice as a physician in London, and from 1800 until his death he was chief physician at Saint Thomas's Hospital. His scientific observations were characterized by keen observation and a sincere devotion to the work. He was elected a Fellow of the Royal Society in 1793 and in 1814 he received the society's Rumford medal for his 'Essay on Dew' (1814). Author of 'An Essay on Single Vision with Two Eyes' (1792); 'On the Colour of the Blood' (1797); 'On Vision' (1811), etc. A selection from his essays and his autobiography were published (1818).

**WELLS**, wēlz, England, ancient city and municipal borough, county of Somerset; at the foot of the Mendip Hills; 15 miles southwest of Bath. The cathedral, a remarkably beautiful edifice, begun 704, enlarged 1138, is for the most part in Early English; but its western front, one of the noblest façades in the kingdom, and enriched with 300 statues, is in Gothic. The bishop's palace, founded 1088, is surrounded by a moat supplied from the abundant source of Saint Andrew's Well—from which the town is said to derive its name—and by lofty walls. There are no manufactures, and the trade is chiefly retail. Pop. 4,655.

**WELLS COLLEGE**, a college for women, located in Aurora, N. Y. It was founded in 1863 by Henry Wells, who at that time deeded to the trustees the main building and 20 acres of land. It is undenominational in its control and policy. In 1888 the main building was destroyed by fire, but immediately rebuilt without crippling the work of the college. A preparatory course was at first maintained, but was abolished in 1896, when the range of elective

system was also greatly increased. Formerly the three degrees of A.B., B.L. and B.S. were conferred, but the A.B. degree is now granted for the completion of the course, which is largely elective, especially in the last two years. Biblical literature is among the required studies, courses in the theory and history of music count toward the degree, but technical musical work does not. The discipline is by a system of student self-government, based on a series of simple rules adopted and enforced by the students themselves. The college is situated on Cayuga Lake, and the College Boat Club has erected a boathouse for the use of their members. The college buildings include the main hall, Morgan Hall, a dormitory (the former residence of the founder), a gymnasium, a science hall, and the administration building. The students in 1917 numbered 206, the faculty 34. There are over 30,000 volumes in the library and the productive funds total \$521,720. Wells seeks to maintain its distinctive character as a small college, maintaining a high standard of college work, but not attempting university methods.

**WELLS AND WELL-SINKING.** Wells are excavations for water or other substances such as petroleum, gas or salt; well-sinking is, therefore, the operation by which deep holes of comparatively small diameter are sunk into the earth. Similar holes are drilled in search of coal, iron ore and other minerals, and, although in this case water is not the object in view, yet work of this character may properly be regarded as well-sinking. The process of well-sinking usually implies also the casing of the well either to guard against the choking of the well or to shut out liquids from all strata except that which the well is designed to tap. Wells are variously classified according to the method of sinking, a dug, bored, driven, drilled and jetted; a curb, case or tube wells according to the manner of lining them; as open, shallow or deep; and as artesian, flowing, non-flowing and pumping.

As regards the dug well, the method employed is to excavate it with pick, shovel or drill, shoring the sides with stout planking as the excavation proceeds.

Boring or drilling, however, differs essentially from digging in that all the operations are conducted from the surface, the hole being from 3 to 27 inches or more in diameter. Two distinct methods of well-sinking are commonly included under the terms well-drilling and well-boring, viz., the grinding with pressure, by which a hole is made, and the pounding or shattering of rocks by a heavy chisel-pointed bar. The two methods and the machinery adapted to their application are represented in their highest development on the one hand by the diamond-drill and on the other by the rope-drill or ordinary oil-well apparatus so well known in America. The first cuts or bores a hole, either cylindrical or annular, in any desired direction; the other pounds and shatters a hole by its own weight, descending vertically. The pounding or percussion drill is in common use for sinking deep wells either for fresh water, brine, petroleum or gas, while the diamond drill is only occasionally used for this purpose, finding the greatest utility in exploring the harder, inclined rocks for coal,

iron ore, the precious metals, etc. The percussion drill consists of an iron bar tipped with steel drawn to a blunt cutting edge, which is raised repeatedly a few inches and dropped upon a rock, thereby cutting a depression. By slightly turning the bar each time it is raised and causing the chisel edge to strike across the mark left by the preceding blow the depression gradually becomes a nearly circular hole. The hole gradually deepens until the powdered rock prevents further progress. Water is now put into the hole and makes a soft mud of the rock dust, which is now drawn out, and the drilling is resumed. To manipulate long, heavy tools required for a deep well the latter are usually suspended from ropes. More or less complicated machinery is employed but the essential parts of the operation are as described above—raising and letting fall the drill and withdrawing the pulverized rock at regular intervals. The greater number of deep wells are now drilled by steam or gasoline power, while hand and horsepower are used for shallow wells in localities where labor is cheap.

Wells varying from 1,000 to 2,000 feet and over in depth are being drilled in the United States at the rate of about 500 a month. These are mainly in the oil and gas regions of the country, such as Indiana, Ohio and Pennsylvania. The machinery in common use, whether for water or oil, has been developed and brought to its present high degree of perfection in these oil-fields, where certain standard sizes and patterns have been adopted after years of trial. The most prominent object about a deep-drilling well is the derrick or rig, a framework tower 20 feet square at bottom, tapering to four feet at top, and usually 72 to 100 feet high. This tower is for the purpose of carrying two pulleys, the crown pulley in the centre and the block through which the sand-line runs. Over the crown pulley runs the cable by which the drilling tools are suspended and raised or lowered, while the sand-line is a smaller rope and to draw out the sand-pump or bailer, by which the hole is cleaned at short intervals during the drilling. At one side of the rig are the bull-wheels or windlass upon which the cable is wound, and at the other the walking-beam, a heavy timber 20 feet long hung in the centre so that it can oscillate up and down. One end comes directly over the hole, and the other can be attached by a pitman to a crank driven by the band-wheel, which in turn is belted to the engine. This large band-wheel can also be made to run the sand-reel or long windlass carrying the sand-line, one end of the reel being drawn when in use by a powerful lever against the band-wheel.

The hand-wheel imparts motion in a third way, by means of an endless bull-rope turning the bull-wheels which wind or unwind the cable. The drilling "set" consists generally of a bit four feet long, weighing 150 pounds; an auger-stem about 40 feet long, and weighing 1,300 pounds; the jars, six feet or more long, weighing 300 pounds; the sinker bar, 16 feet long, weighing 600 pounds; and the rope socket of about 75 pounds on top. The total length of the string of tools is 60 feet, and when suspended from the crown pulley by means of the cable, one and seven-eighths inches in diameter, the tools swing inside the derrick, and when

necessary can be stood up out of the hole. When in use the tools are lowered into the hole by means of the bull-wheels, then are raised a few inches, and the rope is securely clamped to the temper-screw hanging to the end of the walking-beam, the rope above the point of attachment being allowed to hang freely. The means of the temper-screw the tools are gradually lowered as drilling progresses until the screw running down five feet. The bit cutting-tool is faced with steel, has an obtuse cutting edge. The auger-stem is to give rigidity to the bit and efficiency to the blow. The jars consist of two long, flat links, faced on one side with steel, playing into each other and admitting a vertical movement of about one or two inches. They divide the string of tools into two parts, acting in a degree independent of each other. Above the jars is the sinker bar whose purpose is to give efficiency to the downward blow of the upper half of the jars. The jars are used mainly to loosen the tools when the lower part becomes wedged or stuck in the hole. After drilling has progressed the length of the "screw"—viz., five feet—the tools are drawn out and water thrown in if the hole is dry. A sand-pump or bailer, a tube 16 feet or more long with a valve in the bottom, is then run on the end of the sand-line, and when mud and water is drawn out and emptied the operation being repeated until the hole is cleared from mud. Then a new bit, sharpened to its full width, is put on the end of the tool string and are run in, and drilling proceeds as before. In some localities drilling is done by wooden rods instead of the cable. Where the rocks are soft or unconsolidated it is necessary that the well be lined with casing. This casing not only keeps the walls from falling in, but, if properly set, keeps out surface waters. It is usual to drill the hole as deep as possible, and then slip the casing in, its diameter being less than that of the drill. In some cases this cannot be done on account of the instability of the walls, and then it is necessary to adopt some modification, as, for instance, to drill ahead a short distance, and then to pull the casing down. The latter is usually wrought iron, put together by means of joints and collars, and capable of standing a pressure of from 1,000 to 3,000 pounds per square inch. In regard to the cost of drilling wells, it is safe to assume that wells of 100 feet and under cost about \$6 per foot; from 1,000 to 1,500 feet are relatively cheap, being about from \$4 to \$5 per foot; and deep wells are again relatively expensive, the cause of the special machinery involved cost over \$6 per foot. An essential part of well-sinking equipment are several devices "fishing tools" to be used in case a rope or the drill becomes wedged in the hole.

Shallow wells are sometimes driven by hammer blows and are known as driven or driven wells. The tube so driven usually has a joint end with perforation on the sides of the sections.

Well sinking has been carried on for centuries, but it was not until the latter part of the 19th century that improved methods and equipment made possible the boring of deep wells. In 1834-41 a well was sunk at Grenelle, near Paris, to a depth of 1,798 feet; not until 1850 a

singen, Bavaria, was this exceeded, when a salt spring was tapped at 1,878 feet. In 1855-57 a well 1,923 feet was sunk at Passy, near Paris.

The greatest depth reached by human agency is 7,579 feet in the Lake well, completed in 1919, at a point about eight miles southeast of Fairmont, W. Va. Its mouth is about 1,300 feet above sea-level and it was bored in an unsuccessful attempt to reach certain sands in which gas and oil were expected. The next deepest is a well 7,386 feet deep on the Goff farm eight miles northeast of Clarksburg in northern West Virginia. The third deepest is a well at Czuchow, Germany, which is 7,348 feet deep. The fourth in order is the Geary well 20 miles southwest of Pittsburgh, Pa., 7,248 feet deep. The following are more than 5,000 feet deep.

	Feet
Paruschowitz, Upper Silesia, Germany.....	6,572½
Schladenbach, near Leipzig, Germany.....	5,735
Springs, 25 miles east of Johannesburg, Africa.	5,582
West Elizabeth, 12 miles south of Pittsburgh, Pa.	5,575
Doornkloof, Transvaal.....	5,560
Aleppo Township, southern Greene County, Pa.....	5,322
Jacksonville, Fla.....	5,000

There are many from 3,000 to 5,000 feet deep. The deepest mine in the world is shaft three of the Tamarack Copper Mine, Houghton, Mich., 5,200 feet, and other copper mines in Lake Superior region are from 4,000 to 5,000 feet deep. Consult Isler, C., 'Well-Boring for Water, Brine and Oil' (2d ed., revised and enlarged, London 1911).

**WELLSBORO**, wëlz'bür-ō, Pa., borough, county-seat of Tioga County, on the Fall Brook Railroad (New York Central Railroad, about 35 miles north of Williamsport. It is in an agricultural and coal mining region. It has large chemical works, wagon and carriage factories, marble works, lumber mills, tanneries, cut glass works and machine shops. There are two banks and three newspapers. Pop. 3,183.

**WELLSBURG**, W. Va., city, county-seat of Brooke County, on the Ohio River, and on the Pittsburgh, Cincinnati, Chicago and Saint Louis Railroad, about 15 miles north of Wheeling. It is in an agricultural and sheep-raising region, and in the vicinity are numerous coal mines and natural gas. It has a fine city-hall, paper mills, glass factories, a sack factory, grist mill, sheet metal works and machine shop. There are three banks, a daily and two weekly newspapers. The town was founded in 1790. Pop. 4,200.

**WELLSTON**, Mo., city in Saint Louis County, on the Missouri River, and on the western outskirts of Saint Louis. Eden College and the Eden and the McKinley seminaries are located here. There are stockyards, lumber yards and manufactures of electrical goods, steel ranges, tools, wire rope and other articles. Pop. 7,312.

**WELLSTON**, wëlz'ton, Ohio, city in Jackson County, on the Cincinnati, Hamilton and Dayton, the Ohio Southwestern, the Detroit, Toledo and Ironton, the Hocking Valley and the Baltimore and Ohio Southwestern railroads, about 72 miles in direct line southeast of Columbus. It is in an agricultural and coal-mining region and has considerable iron manufacturing. There are 40 factories with annual products of \$1,500,000. The chief industrial establishments are foundries, blast furnaces,

barrel factory, machine shops, cement works and brick works. The city has a high school, public graded schools and a public library. There are two banks and a daily and two weekly newspapers. The city owns and operates the electric-light plant and the waterworks. The government is vested in a mayor who holds office two years and a city council. The place was settled in 1871 and in 1876 was incorporated. Pop. 6,875.

**WELLSVILLE**, N. Y., village in Allegany County, on the Genesee River, and on the Erie and the Buffalo and Southern railroads, about 20 miles southwest of Hornellsville. It is in an agricultural and dairy region, and in the vicinity are a number of oil wells. It has foundries, machine shops, creameries, flour mill, tanneries and cigar factories. There are two national banks and a daily and other newspapers. It has a high school, graded elementary schools and a public library. Pop. about 5,000.

**WELLSVILLE**, Ohio, city in Columbiana County, on the Ohio River, and on the Pittsburgh, Fort Wayne and Chicago Railroad, about 85 miles southwest of Cleveland. It is in an agricultural and coal-mining region, and in the vicinity are valuable deposits of fire clay. The chief manufacturing establishments are machine shops, foundries, iron and steel works, brick and tile works, potteries, nail factory, boiler works and railroad shops. There are 60 factories, whose annual finished products total \$2,000,000. There are three banks and a daily newspaper, nine churches, a high school, public and parish schools and a public library. The city owns and operates the waterworks. Pop. about 7,769.

**WELSBACH** (wëlz'bäh) **LIGHT**, an invention of Carl Auer von Welsbach, an Austrian, in 1884. As now used it is the familiar gas mantle hung over a gas jet to increase the illumination. It is based upon the discovery that certain materials become incandescent at a low temperature. The process followed is to saturate a combustible filament in the form of a network with a solution of a salt of a refractory earth, such as zirconium. It is then dried out and burned, the combustible element disappearing and leaving a frame of refractory material, which becomes incandescent at a low temperature.

**WELSH**, Herbert, American reformer: b. Philadelphia, Pa., 4 Dec. 1851. He was graduated from the University of Pennsylvania in 1871; studied art in Philadelphia and in Paris with Bonnat; and practised as an artist in Philadelphia for several years. Visiting the Sioux reservation, impressed with the belief that the Indians required only a just and consistent treatment by the government and the extension of Christian missions to become civilized, he began a movement to secure to them their rights, which resulted in the organization of the Indian Rights Association in 1882. He became corresponding secretary of this association and has been active in its work, which has been instrumental in securing the passage of a bill providing for the individual ownership of land and the application of the civil service law to the Indian service. He also took a leading part in the reform movement in Pennsylvania State politics in 1890; and in 1895 established a weekly

periodical, *City and State*, published in the interests of good government. He strongly opposed the tendency toward imperialism and severely criticized the government's policy and the evils attending the army's occupation of the Philippines. He has written 'Four Weeks among some of the Sioux Tribes'; 'Civilization among the Sioux Indians'; 'A Visit to the Navajo, Pueblo, and Tualpais Indians'; 'The Other Man's Country' (1900), dealing with the Philippine question.

**WELSH, John**, American merchant: b. Philadelphia, 9 Nov. 1805; d. there, 10 April 1886. He was educated in his native city, where he became prominent in business and was active in public affairs in many capacities, having large railroad and financial interests. He was a member of the Sinking Fund Commission, president of the Philadelphia Board of Trade, etc., and rendered efficient service in promoting relief measures during the Civil War, especially in connection with the Philadelphia Sanitary Fair, in 1864, of which he was president, and which raised over \$1,000,000 for army hospital work. In 1873 he became president of the Board of Finance of the Centennial Exhibition, receiving from the citizens of Philadelphia, at its close, a gold medal and the sum of \$50,000, with which he endowed the John Welsh chair of English literature in the University of Pennsylvania. In 1878 he went as Minister to England, but in the following year resigned.

**WELSH, Robert E.**, Canadian Presbyterian clergyman and educator: b. New Cumnock, Scotland, 20 March 1857. He was educated at Glasgow and Edinburgh Universities, was ordained in the Presbyterian ministry in 1880 and went to Japan as a missionary. He was in charge of Saint Paul's, Harrowgate, Yorkshire, in 1882-87, and of Saint George's, Brondesbury, London, in 1887-1904. He was general secretary to the Canadian Bible Society in 1905-07, and since 1907 he has been professor of apologetics and church history at the Montreal Presbyterian College. Author of 'In Relief from Doubt' (1895); 'God's Gentleman' (1898); 'The Challenge to Christian Missions' (1902); 'Man to Man' (1905), etc.

**WELSH CALVINISTIC METHODISTS**, a designation sometimes given to the Calvinistic Methodists, because Wales is the great seat of the sect. The Calvinistic Methodists are distinguished by their Calvinistic sentiments from the ordinary Wesleyans, who are Arminian. Whitfield is regarded as the father and founder of Calvinistic Methodism. Members of this sect have been active in seeking to bring about the disestablishment of the Anglican Church in Wales. See **METHODIST CHURCHES OF THE WORLD; PRESBYTERIANISM.**

**WELSH LANGUAGE AND LITERATURE.** See **CELTIC LANGUAGES.**

**WELWITSCHIA**, wël-wich'ti-ä, a genus of plants of the family *Gnetaceæ*, containing only one species, *W. mirabilis*. This species is confined to the deserts of Southwest Africa, where it was discovered in 1860 by Friedrich Welwitsch. It has a short and top-shaped stem which never grows much above the surface, but increases in thickness until it may be three feet in diameter, and bears a pair of large opposite leaves. These leaves last throughout the whole

lifetime of the plant and become ultimately torn up longitudinally into long strips, which trail on the surface of the ground. Two cotyledons which are like short-lived leaves of much smaller size precede them. The flowers of the plant grow in cones like those of many conifers, the cones being arranged in panicles on the end of the stem between the two leaves. The female cones are much larger than the male ones and in fruit are of a scarlet color.

**WEMYSS**, weems, Francis Wemyss-Charteris, 10th Earl of Wemyss and Baron Elcho, English noble: b. 4 Aug. 1818; d. 30 June 1914. He was educated at Edinburgh Academy, graduated at Christchurch, Oxford, and became (1841-46) member of Parliament for East Gloucestershire, then (1847-83) member for Haddingtonshire, and (1852-55) he was Lord of the Treasury. He was aide-de-camp to the late Queen Victoria.

**WEN**, an encysted tumor, or sebaceous cyst, varying in size, occurring in different parts of the body, but mostly on the scalp and neck; commonly situated immediately under the skin. The causes of their formation are not understood, but a strongly marked tendency to such swellings exists in particular individuals, leading to the belief in constitutional causes. At its commencement the wen is indolent, and it is often many years before it attains any considerable size. It is enclosed in a sac, its contents being sometimes sebaceous matter, in other cases serum, or a thin fetid brown or black fluid. Sometimes the sac contains cartilaginous or even osseous matter. Frequently the sac, especially when small, may be punctured, and its contents pressed out; but sometimes this gives rise to very severe inflammatory action. Another and safe mode of treatment is to dissect them out with the knife wherever their position will admit of it, care being taken to remove the whole of the cyst.

**WEN-CHOW**, wün'chow', China, a treaty port (since 1887) in the province of Che-kiang, on the estuary of the Ta-kai River, flowing into the China Sea, about 200 miles south by west of Shanghai. Ruined palaces, gates, triumphal arches and an immense wall are among the numerous signs of its vanished greatness, but it is still a comparatively clean town, with broad streets and numerous canals. Among buildings of recent erection are the custom-house and the branch of the Imperial Chinese Post Office. The chief imports are cottons, kerosene, sugar, opium, iron and woollens; the principal exports are tea, umbrellas, timber and oranges. The average annual values of the imports and exports during several recent years were about \$1,500,000 and \$1,250,000, respectively. The tonnage of shipping is about 40,000 per annum. There is also a considerable junk trade. Pop. 205,000.

**WENATCHEE**, Wash., city and county-seat of Chelan County, on Columbia River, 96 miles southeast of Seattle, and on the Great Northern Railroad. It is situated in the midst of superb scenery, and the surrounding district, for which it is a shipping centre, is interested in agriculture and fruit raising. Pop. 4,050.

**WENATCHI.** See **SALISHAN INDIANS.**

**WENCESLAS**, wén'sēs-lās or -lās, or **WENZEL**, emperor of Germany and king of Bohemia: b. 1361; d. Schlagfluss, 16 Aug. 1419. He was the son of Charles IV (q.v.), whom he succeeded in 1378. In 1394 the Bohemian nobility formed a conspiracy against him and held him prisoner at Prague, but later released him. Through the influence of the archbishop of Mainz, whose enmity he had aroused by demanding the resignation of the rival popes, Benedict XIII and Boniface IX, he was deposed by the Imperial electors, while the Elector Palatine Rupert was chosen to succeed him. In Bohemia he supported John Huss (q.v.) and the latter's party, and in 1409 compelled by a decree the departure of the Germans from the University of Prague. Shortly afterward he resigned the royal title. Consult Lindner, 'Geschichte des Deutschen Reiches unter König Wenzel' (1875-80).

**WEND LANGUAGE.** The language of the Wends is similar to the other branches of the northwestern stem of the Slavic languages, the Polish and the Bohemian. It is divided into the dialect of Lower Lusatia, which is but little developed, and that of Upper Lusatia. The latter is subdivided into the Evangelical dialect, near Bautzen; the Catholic dialect, near Kamenz, and in the northwest; and the north-eastern dialect. The differences are mostly confined to shades of pronunciation. The stock of words in the present language of the Wends is largely mixed with German elements. Orthography has always been in a very unsettled condition. In their publications, the Wends have mostly made use of the German letters. There are eight vowels, *a, o, u, e, i*, all of which are pronounced as in German and Italian, *ö* (between *o* in *note* and *u* in *full*), *é* (like long English *e*), and *y* (approaching the German *ü*). There are 32 consonants. There is no article. Nouns ending in a consonant are mostly masculine, those in *a* and *i* feminine, and those in *o* and *e* neuter. There are seven declensions. The language has a dual number. There are seven cases. The adjectives end in *y, i* (masculine), *a* (feminine), *o* and *e* (neuter). The comparative is formed by the termination *isi*, and in order to form the superlative the syllable *naj* is placed before the comparative. The personal pronouns are irregular; the others are declined like adjectives. The verb has six tenses and five moods, besides a gerund; and three participles. Till about the middle of the 19th century Wendish literature consisted almost wholly of ecclesiastical and religious works, and works relating to the needs of peasant life, but there has since been a revival of national feeling, accompanied by a more extended literature. There are grammars of the Wendish language by Ticinus (Prague 1679); Matthäi (1721); Seiler (Bautzen 1830), and Jordan (Prague 1841).

**WENDELL, Barrett**, American educator and author: b. Boston, Mass., 23 Aug. 1855. Graduated from Harvard in 1877, he studied also in the Harvard Law School, in 1880-88 was instructor in English at Harvard, in 1888-98 assistant professor, and in 1898 became professor. He was Clark lecturer at Trinity College, Cambridge, England, in 1902. Among his works are 'The Duchess Emilia' (1885);

'Rankell's Remains' (1897); 'English Composition' (1891); 'Cotton Mather' (1891); 'Stelligeri, and Other Essays Concerning America' (1893); 'William Shakespere' (1894); 'A Literary History of America' (1900; in the 'Library of Literary History'), a scholarly work, though much criticized for its unjust attitude toward certain writers; and 'Raleigh in Guiana' (1902), an attempt at imitation of the Elizabethan drama; 'Liberty, Union and Democracy' (1906); 'The Mystery of Education' (1909).

**WENDS**, a former powerful Slavic tribe settled in Germany, now represented by the Slavic people of Upper and Lower Lusatia, who call themselves Serbs (*Serbjo*), whence the name Sorbs, often applied to them by German authorities. In the earliest historical times the Sorbs occupied the country from the Saale to the Bober, and from the latitude of Berlin south to the Erzgebirge; but the Wends are now confined to a small territory (about 1,270 square miles) in the upper Spree Valley, extending from south of Bautzen to north of Kottbus. The larger part of this Wendish region belongs to the Prussian provinces of Brandenburg and Silesia, the smaller southern part being included in the kingdom of Saxony (circle of Bautzen). The Wends are completely surrounded by Germans, and being thus cut off from contact with the other Slavs, they are becoming slowly Germanized. Their language, known as Sorbian, falls into two dialects Upper and Lower Sorbian, which are spoken in the south and the north of the territory, respectively. (See WEND LANGUAGE). The total number of Wends is about 120,000, of whom about 50,000 live in Saxony and 70,000 in Prussia. About 12,000 are Roman Catholics, the remainder being chiefly Lutherans.

**WENER**, vā'nēr, or **VENERN**, Sweden, the largest lake of the country, and after those of Ladoga and Onega the largest in Europe, situated centrally between the läns of Wernmland, Dalsland and Wester Götland. It is 147 feet above sea-level, and of irregular shape. Its greatest length, northeast to southwest, is about 90 miles; and its breadth may average about 30 miles, though in its southern part, where two peninsulas stretch far into it from opposite directions, it is not more than 15 miles. This distance is still further narrowed by a group of small islands, and hence the part of the lake above these peninsulas is sometimes considered as Wener proper, while the part below is called Lake Dalbo. The area covered by both is about 3,000 square miles. By far the most important feeder is the Klar-elf, which pours in at its north end the accumulated water of a course of more than 250 miles. Its only proper outlet is at Wenersborg at its southwestern extremity, where its superfluous waters are received by the Göta-elf, flowing thence to the Cattegat. In summer steamers and other vessels ply regularly upon the lake; in winter it is frozen for several months, and crossed by sledges. It abounds with fish, particularly trout. The Göta Canal connects Lake Wener with Lake Wetter, and the Dalsland Canal connects it with Fredrikshald in Norway.

**WENLEY, Robert Mark**, American educator: b. Edinburgh, Scotland, July 1861. He

was graduated from the University of Glasgow in 1884, and later studied in Edinburgh and on the Continent. He was in charge of the philosophical department of Queen Margaret College, Glasgow, in 1888-95, and since 1896 has been at the head of that department in the University of Michigan. He has published 'Socrates and Christ' (1889); 'University Extension Movement in Scotland' (1895); 'Contemporary Theology and Theism' (1897); 'Preparation for Christianity in the Ancient World' (1898); 'Kant and His Philosophical Revolution' (1910); 'The Anarchist Ideal' (1913); 'Robert Flint' (1914), etc. He was an associate editor of the 'Dictionary of Philosophy.'

**WENLOCK GROUP**, a British formation of the Upper Silurian geological series. It includes shales and limestones, and is below the Ludlow group and above the Upper Llandovery group, these three comprising the Upper Silurian groups. The Wenlock formation is about 4,000 feet thick, and the fauna has been classed as consisting of 171 genera and 530 species, but many supposed vegetable remains are almost certainly not such. See **SILURIAN**.

**WENSLEYDALE**, wenz'li-däl, **James Parke**, **BARON**, English jurist: b. Highfield, near Liverpool, 22 March 1782; d. Amptill Park, Bedfordshire, 25 Feb. 1868. Graduated from Trinity College, Cambridge, in 1803, he was called to the bar at the Inner Temple in 1813, went the northern circuit and became known for his wide knowledge of common law. In 1828 he was made a justice of the Court of King's Bench, in 1834 was transferred to the Court of the Exchequer. Here he remained strongly influential until his resignation in 1856, when he entered the Lords as Baron Wensleydale of Walton (Lancaster). In Parliament he spoke rarely, and chiefly on legal questions. His judgments were highly ranked. Consult Foss, 'The Judges of England' (1848-64), or the abridgment of the same, 'Biographia Juridica' (1870); Manson, 'Builders of Our Law' (1895).

**WENTLETRAP**, a gastropod mollusk, allied to the turret shells and of the genus *Scalaria*, in which the shell is turreted, spiral and ornamented with elevated rib-like processes, crossing the whorls lengthwise of the shell. In some species the spiral is closed; but in the "true" wentletraps the whorls are open, that is, separated. Of the former, some are found in northern seas, and the latter are all natives of warm seas. They are inhabitants of deep waters, but their shells are cast up in great numbers on sandy coasts. They are carnivorous in habits. The famous precious wentletrap, or royal staircase (*Scalaria pretiosa*), formerly brought prices ranging as high as \$250 when purchased for the conchologist's cabinet, but its value in the present day is small. Its shell is about two inches long, and twisted in a wide spiral form, and is generally pale-yellow with white ribs.

**WENTWORTH**, wënt'werth, **Benning**, English governor of New Hampshire: b. Portsmouth, N. H., 24 July 1696; d. there, 14 Oct. 1770. He was graduated at Harvard in 1715, became a merchant at Portsmouth, which town he frequently represented in the provincial

assembly, was appointed a king's council 1734, and when in 1741 New Hampshire made a distinct province he became its governor. He so continued until 1767, when resigned. He was authorized by the Crown to grant patents of unoccupied land, and began making grants on the west side Connecticut River, in what is now New Vermont. These grants were considered the colonial government of New York as its domain, and, as Governor Wentworth stoutly maintained for a time his authority, a collision so famous in the history of Vermont respecting the New Hampshire grants ensued. (See **VERMONT, History**). Governor Wentworth exacted heavy fees for his grants of land, and thus accumulated a large fortune, and in all of them stipulated for the location of a lot for an Episcopal church. One town of Bennington, Vt., was named in honor of him. After his resignation as governor he gave to Dartmouth College 500 acres of land on which the college buildings were erected. For an account of his second marriage see Longfellow's poem 'Lady Wentworth.'

**WENTWORTH, Charles**, 2d **MARQUIS OF ROCKINGHAM**.

**WENTWORTH, George**, American mathematician, son of G. A. Wentworth (q.v.) b. 1835; graduated at Harvard University in 1858, and from 1859 was his assistant in the compilation of text-books. Since his father's death in 1906 he has collaborated with D. E. Smith (q.v.) in the Wentworth-Smith mathematical

**WENTWORTH, George**, American mathematician: b. Wakefield, N. H., 1835; d. Dover, N. H., 24 May 1906. He graduated from Harvard in 1858, and in 1861 was professor of mathematics at Exeter Academy. With G. A. Hill he wrote a series of textbooks on algebra, trigonometry and physics, and he was author of the Wentworth Series of mathematical works comprising about 40 volumes, among which 'Elements of Geometry' (1878); 'Spherical and Navigation' (1882); 'Higher Algebra' (1891), etc.

**WENTWORTH, SIR JOHN**, English colonial governor of New Hampshire, and ward of Nova Scotia: b. Portsmouth, N. H., Aug. 1737; d. Halifax, N. S., 8 Aug. 1800. He was a nephew of Benning Wentworth. He was graduated at Harvard in 1756, a classmate of John Adams, became a lawyer, and in 1765 was the agent of New Hampshire to present petitions in London. While there he was appointed to succeed Benning Wentworth as governor of New Hampshire. At the same time he was made surveyor of the king's woods for all New England. Having landed at Charleston in March 1767, he traveled through the colonies, registering in each his commission as surveyor, and arrived at Portsmouth in June. The office of governor was at that time extremely difficult one by reason of the intense discontent of the colonists. At the first, Wentworth's administration was very unpopular, remonstrated against the taxes imposed by the English government, but sought to maintain the loyalty of the colony, and was success-

venting the assent of Portsmouth to the non-importation agreements until 1770. In this he was aided by the fact that the Portsmouth merchants were disinclined to forego such profits as they might still obtain despite the crippled state of commerce. When the last attempt was made to compel the colonies to receive East Indian tea, he took advantage of lack of instructions from the government, and had the consignee reship the cargo to Halifax. His authority ended, however, when it was learned that he had endeavored to comply with the request of General Gage to obtain carpenters to construct barracks for the British troops at Boston, after Massachusetts workmen had refused the task. On 14 Dec. 1774 an armed attack was made on Fort William and Mary (now Fort Constitution) on Great Island, at the entrance to Portsmouth Harbor, and 100 barrels of powder and some cannon and muskets were taken. Wentworth finally found it advisable to withdraw to the fort, and then to a warship in the harbor. At the Isle of Shoals he prorogued the assembly, his last official act. He went to Boston, and thence to England. From 1792 to 1808 he was lieutenant-governor of Nova Scotia. He was active in the foundation of Dartmouth College. Nine manuscript volumes of his correspondence are in the public records of Halifax. He was made a baronet in 1795.

**WENTWORTH, John**, American journalist: b. Sandwich, N. H., 5 March 1815; d. Chicago, Ill., 16 Oct. 1888. He was graduated from Dartmouth in 1836 and in the same year went to Chicago where for 25 years he was owner and editor of the *Democrat*. He studied law, was admitted to the bar in 1841, and in 1843 was elected to Congress where he served six terms. He introduced the first steam fire engine into Chicago, was active in procuring the city charter, an earnest promoter of the public school system, and in 1857 and 1860 was elected mayor. He dissolved his connection with the *Democrat* in 1861, but did not retire from active life for many years. He gave \$10,000 to Dartmouth College, was president of its alumni in 1883 and wrote 'Descendants of Elder William Wentworth' (1850) and 'History of the Wentworth Family' (1878).

**WENTWORTH, Thomas**. See STRAF-FORD, 1ST EARL OF.

**WENTWORTH, William Charles**, Australian statesman: b. Norfolk Island, New South Wales, 26 Oct. 1793; d. near Wimbourne, Dorset, England, 20 March 1872. He was the son of a government surgeon at Norfolk Island, then a penal colony, and was educated in England, making one return visit to Australia in the meantime. He studied at Cambridge University and at Middle Temple, and was called to the English bar in 1822. He then returned to Sydney and speedily gained a large law practice. He affiliated himself with the cause of the "emancipists," the ex-convict class, as against the "exclusivists," made up of civil and military officers and gentlemen settlers, maintaining that South Wales was intended primarily for the "emancipists" who had earned their freedom and were entitled to preference as colonists. He was also an advocate of self-government for Australia, and with Dr. Wardwell, a fellow-lawyer, he in 1824 founded the

*Australian*, which was devoted to both projects. He was one of the founders of the "Patriotic Association," and was a leader in the long struggle for self-government which was finally won in 1842, and which victory was generally recognized as being largely due to his labors. He was a member of the first legislative council, and was the leader of the "Squatter" party. He was also foremost in the struggle for a new constitution for the Colony in 1854. He afterward lived for several years in England and founded in London the General Association for the Australian Colonies. He earnestly advocated a federal assembly for Australia and is regarded as the originator of the Australian Commonwealth movement. He returned to Sydney in 1861 and became president of the new legislative council, but after 1862 he lived in England. His body was taken to New South Wales, the legislature unanimously voting him a public funeral. Author of 'A Statistical Account of the British Settlements in Australasia' (1819); 'Australasia' poem (1823).

**WERFF, vèrf, Adriaan Van der**, Dutch painter: b. Kralingen, near Rotterdam, 21 Jan. 1659; d. Rotterdam, 12 Nov. 1722. He became a pupil of Van der Neer, settled in Rotterdam, and in 1696 attracted the notice of the Elector Palatine, who was thenceforward his liberal patron and who ennobled him in 1703. Among his celebrated paintings are the 'Judgment of Solomon'; 'Christ Carried to the Sepulcher'; 'Ecce Homo'; 'Abraham with Sarah and Hagar,' and 'Magdalen in the Wilderness.' Van der Werff was particularly noted for his small historical pieces, which are most exquisitely finished, and are still in high request. His brother and pupil, PIETER VAN DER WERFF (1665-1718), painted portraits and domestic pieces.

**WERGELAND, vèr'gè-länd, Henrik**, Norwegian poet: b. Christiansand, 17 June 1808; d. Christiania, 12 July 1845. He studied at Christiania, in 1836 became custodian of the university library, and in 1840 keeper of the Norwegian archives. He was one of the leaders of the Ultra-Norwegian party, waging war on all things Danish, but found opponents in Welhaven and the latter's school. In 1830 he published the dramatic poem 'The Creation, Man and Messiah,' a work of formidable length and slight literary merit. His chief publications are the narrative poems, 'Jan van Huysum's Flower-Piece' (1840); 'The Swallow' (1841); 'The Jew' (1842); 'The Jewess' (1844), and 'The English Pilot' (1844), which take high rank in Norwegian verse. His complete collected works appeared in 1852-57, a selection in 1859. Consult the biographies by Lassen (1867), Schwanenflügel (1877) and Skavlan (1892).

**WERGILD, wèr'gild, or WEREGILD**, wèr'gild, derived from the Anglo-Saxon *wer*, a man, and *geld*, satisfaction, and meaning the price in money paid either kinsmen or to the state, or both, as satisfaction in a case of homicide or other crime against the person. The wergild extended to offenses of the highest grade. It was also sometimes exacted when the killing was not criminal, as in the case of a thief slain in battle. It was eminently a Teutonic institution, and the amount of wergild varied with different tribes. Among the Anglo-

Saxons, the wergild for taking the life of the king was 7,200 shillings; for an eolderman, 2,400 shillings; a king's thegn, 600 and a ceorl, 200. In the Anglo-Saxon period an alderman or eolderman was a much more important personage than the alderman of to-day, the aldermen of all England being the first subjects of the realm, and other aldermen being governors of counties. Even kings were called aldermen. The thegn, or thane, was a minor noble, and the ceorl, or churl, a tenant-at-will of the thane, or he might be simply a serf or farm-laborer. As the value of money, measured by its purchasing power, was far greater than to-day, the wergild for king and alderman and even for thane, must have been prohibitory save for the wealthiest members of the community, or when the state assumed the burden of payment, as in the case of an enemy of high rank killed in war, whose relatives were able to wreak vengeance for his death.

Wergild for a homicide had to be paid to the king and the kindred, and also to the thane, or overlord of the slain man. The relatives were not obliged to accept the price of their kinsman's blood, but might, if they chose, exact life for life. If the relatives were satisfied, however, it was not difficult to make terms with the king and thane. The wergild passed away when Norman succeeded to Anglo-Saxon rule, and while fines continued to be imposed on offenders, there was no escape from the capital penalty for homicide except in trial by combat.

**WERNER**, wér'nér, **Abraham Gottlob**, German mineralogist: b. near Bunzlau, 25 Sept. 1750; d. Dresden, 30 June 1817. In 1775 he was appointed inspector and teacher of mineralogy and mining in the Mining Academy at Freiberg, in which position he remained for the rest of his life. He was the first to separate geology from mineralogy, and to place the former on the basis of observation and experience. The geological theory with which his name is connected is that which attributes the phenomena exhibited by the crust of the earth to the action of water, and is known as the Wernerian or Neptunian theory, in contradistinction to the Huttonian or Plutonic. He was nominated counsellor of the mines of Saxony in 1792, and had a great share in the direction of the Academy of Mining, and in the administration of public works. He published 'Kurze Klassifikation und Beschreibung der Gebirgsarten' (1787); 'Neue Theorie über die Entstehung der Gänge' (1771). Consult 'Life' by Frisch (1825).

**WERNER**, Alfred, Swiss chemist: b. Mulhouse, Alsace, 12 Dec. 1866. He was educated at the Karlsruhe Technical School and the Zurich Polytechnic, and took his Ph.D. at the University of Zurich in 1890. He was assistant to Prof. Georg Lunge at the Zurich Polytechnic in 1889; later was assistant to Berthelot in the Collège de France, and in 1895 he was appointed professor at the University of Zurich, where since 1902 he has been director of the lectures on inorganic chemistry. He was awarded the Nobel Prize in chemistry in 1913. Joint author of 'Ueber die räumliche Anordnung der Atome in stickstoffhaltigen Molekülen' (1891); and author of 'Beiträge zur Theorie der Affinität und Valenz' (1891); 'Beiträge zur Konstitution anorganischer Verbind-

ungen' (1893); 'Lehrbuch der Stereochemie' (1904); 'Ueber die Konstitution und Configuration von Verbindungen höherer Ordnung' (1914), etc.

**WERNER**, Anton Alexander von, German artist: b. Frankfort-on-the-Oder, 5 Aug. 1843; d. 5 Jan. 1915. He studied at the Academy at Karlsruhe and later in Paris and Italy. He executed several state commissions after his return from Italy, and was commissioned to accompany the general staff of the Third Army corps in France during the Franco-Prussian War. He became professor at the Berlin Academy in 1875, and director of the Berlin Academy of Fine Arts in 1875. His paintings, particularly those of the Franco-Prussian War, are of considerable artistic value. Among his works are 'Capitulation of Sedan'; 'Meeting of Bismarck and Napoleon III at Donchery'; 'Proclamation of the German Empire at Versailles'; 'Congress of Berlin,' and several portraits of ex-Emperor William II.

**WERNER**, Friedrich Ludwig Za..., German dramatist: b. Königsberg, 18 Nov. 1801; d. Vienna, 17 Jan. 1823. After attending lectures in his native town, he became a chamber secretary in the Prussian service in 1805 obtained a government post in Berlin, but two years later he retired from the service. In 1811 he joined the Roman Catholic Church, and in 1814 was consecrated pastor at Aschaffenburg. Taking up his residence in Vienna, he became known as an eloquent preacher and later was appointed head of the chapter of the cathedral of Kaminiac. His dramatic works reveal much of the powerful pathos characteristic of Schiller, but over a constantly increasing extent, as he advanced in years, by mystical and undramatic elements. The chief of them are 'Die Söhne des Himmels' (1804); 'Das Kreuz an der Ostsee' (1807); 'Martin Luther oder die Weihe der Nation' (1807); 'Attila' (1808); 'Wanda' (1809); 'Die Weihe der Unkraft' (1813), a subsequent retraction of the earlier play on Iphigenia; 'Kunigunde die Heilige' (1815); 'Im Februar' (1815); 'Die Mutter der Makkabeer' (1820).

**WERNERITE**, an important rock-forming mineral, occurring in cleavable, indistinctly-fibrous or columnar masses, or in large, coarse crystals. These are tetrahedral prisms terminated by pyramids, and show prismatic cleavage. The hardness is 3.5 and specific gravity about 2.7. The most common colors are white or gray; lilac is also abundant; occasionally greenish and brown varieties are found. Wernerite is a member of the scapolite group (q.v.) and is intermediate in composition between melionite and wernerite, being a silicate of aluminum, calcium, and sodium, with chlorine. It usually occurs as a crystalline limestone. Among its many localities a few of the most important are Arendal, Norway; Bolton, Mass.; northern New York; Ontario and Quebec. The mineral was named in 1800 in honor of the distinguished mineralogist A. G. Werner.

**WERNZ**, wérnz, Francis Xavier, Diocesan General of the Society of Jesus: b. Reutlingen, Württemberg, 4 Dec. 1842; d. 19 Aug. 1919. He studied philosophy and theology at

Jesuit colleges and (1857) became member of the Society of Jesus after receiving holy orders at Feldkirch, and study of canonical law at Dittion-Hall. In 1883 he was made professor and (1904) became principal of the Gregorian University, Rome. He was commissioner for the codification of canonical law, counsel of the Congregation and other church matters. He wrote 'Jus Decretalium ad Usus Prælectionum' (1898-1904; 2d ed. 1905).

**WERTENBAKER, Thomas Jefferson**, American journalist and educator: b. Charlottesville, Va., 1879. His father was Charles C. Wertenbaker and his mother Frances Leftwich. He was educated at private and public schools, Charlottesville, Va., and at the University of Virginia, receiving the degrees of P.A. and Ph.D. from the latter institution. In 1906-07 Mr. Wertenbaker was telegraph editor of the *Baltimore News*, has taught at the Agricultural and Mechanical College of Texas, the University of Virginia and Princeton University. In 1916 he was married to Miss Sarah Rossetter Marshall of Lexington, Ky. At present he is assistant professor of history and politics at Princeton and editorial writer on the *New York Evening Sun*. He has published 'Patrician and Plebian in Virginia' (1910); and 'Virginia under the Stuarts' (1914).

**WERWOLF**, wër'wulf, or **WEREWOLF**, wër-wulf, a human being transformed into a wolf, according to a belief which has prevailed in all ages and ignorant and superstitious communities. Herodotus, with great naiveté, tells us that when he was in Scythia he heard of a people which once a year changed themselves into wolves, and then resumed their original shape; "but," adds he, "they cannot make me believe such tales, although they not only tell them, but swear to them." But the lycanthropes of the Middle Ages, or *loup-garous*, as they were called by the French, were sorcerers, who during their wolfhood had a most cannibal appetite for human flesh. The Germans called them *Währwölfe*. Many marvelous stories are told by the writers of the Middle Ages of these wolf-men or *loupsgarous*, and numerous authentic narratives remain of victims committed to the flames for this imaginary crime, often on their own confessions.

It is certain that faith in the power of witches to assume the shape of animals, such as wolves, dogs, cats or horses, existed at a comparatively recent time, and is probably not extinguished yet in Western Europe. In the Balkan States, or part of them, belief in the werewolf flourishes to this day, along with the kindred vampire superstition. An old writer says that "the werewolves are certain sorcerers, who, having anointed their bodies with an ointment which they make by the instinct of the devil, and putting on a certain enchanted girdle, do not only unto the view of others seem as wolves, but to their own thinking have both the shape and nature of wolves, so long as they wear the said girdle; and they do dispose of themselves as very wolves, in worrying and killing, and most of human creatures."

The werewolves were said to have in some instances a special hatred of religion and its devotees, and this, coupled with the charge of devouring human flesh, left no doubt as to the fate of anyone who fell under suspicion of

being a werewolf. The superstition itself was doubtless due in part to the brutal and savage aspect of human beings who, owing to melancholia or other forms of insanity, went wild in the woods—an occurrence not infrequent in remote districts in the Middle Ages. It was also in all probability connected with the belief, which was a prominent feature of mythology, in the power of the gods and inferior spirits to enter the bodies of animals, and with the doctrine of transmigration of souls, common alike to the ancient Egyptians, the followers of Pythagoras and the Hindus. See **WITCHCRAFT**.

**WESEL**, vā'zël, Germany, a town in the Rhine province of Prussia, on the right bank of the Rhine, at the mouth of the River Lippe, 35 miles north by west of Düsseldorf. The Rhine is here crossed by a railway and a pontoon bridge, and the Lippe by a railway and two other bridges. The fortifications were demolished in 1890, except the citadel and four outer forts, one of which, Fort Blücher, is on the left bank of the Rhine. This fort was highly developed early in the present century. The Berlin gate, with statues of Hercules and Minerva, dates from 1722. The principal church was founded in the 12th century, and dates in its present form from 1521. It was restored in 1883-96. The town-hall, with a Gothic façade, was completed in 1390. The other buildings and institutions include the Lower Rhine Museum, formerly a French church; the artillery barracks, formerly a Dominican monastery; a royal gymnasium and other higher educational institutions; two hospitals, an orphanage and the fortress prison. Soap, wire and cement are manufactured, and there are also sugar refineries, brick works, flour and oil mills, steam saw-mills, etc., besides a trade in timber, grain, etc. There is ample harbor and quay accommodation. Wesel can be traced back to the 8th century. It was a member of the Hanseatic League, and adopted the Reformation in 1540. It came into Prussian possession in 1814. Pop. 25,000.

**WESER**, vā'zër (Latin, *Visurgis*), a river of Germany formed by the junction of the Fulda and Werra at Münden, between the provinces of Hanover and Hesse-Nassau. It flows tortuously first northwest, then north-northeast between Westphalia and Brunswick and after a circuitous northwestern course, traverses the town and the territory of Bremen, forms the boundary between Hanover and Oldenburg, at Elsfleth turns almost due north, and falls by a wide mouth, incumbered with sandbanks, into the German Ocean. Its whole course is about 480 miles. It is navigable by barges to some distance up both head-streams, but the practical limit of summer navigation is Hameln. The lower part, from Bremen to Bremerhaven, has been deepened and improved for large vessels.

**WESLEY**, wës'li, Charles, English clergyman and hymn-writer, younger brother of John Wesley: b. Epsom, Lincolnshire, 18 Dec. 1707; d. London, 29 March 1788. He was educated at Christ Church, Oxford, and there he began, he says, "to observe the method of study prescribed by the university," adding, "This gained me the harmless nickname of Methodist"—a word at first apparently without religious significance, and meaning one who affected method.

In 1735 he was ordained priest. Charles accompanied his brother to Georgia, where he was not very successful, and having returned to England in 1736, became unlicensed curate of Saint Mary's, Islington, where he remained until 1739. In 1739-56 he was an active itinerant preacher. He differed from his brother on some doctrinal and other points, holding, for example, that perfection must be attained by a gradual process. After residing for some years at Bristol and Bath, he went to London in 1771. He is said to have written more than 1,000 hymns, of which very many came into general use. Consult the biographies by Jackson (1849) and Telford (1866), and Julian, 'Dictionary of Hymnology' (1892).

**WESLEY, John**, English clergyman, founder of Methodism: b. Epworth, Lincolnshire, 17 June 1703; d. London, 2 March 1791. He was a younger son of the Rev. Samuel Wesley (q.v.), and was educated at Charterhouse, and at Christ Church, Oxford. He took his degree in 1724, was ordained deacon in 1725 and became a Fellow of Lincoln College, in which he was appointed Greek lecturer and moderator. He was of a serious and religious turn of mind, and books which impressed him powerfully were the 'Imitatio Christi' and Taylor's 'Holy Living and Holy Dying.' He took priest's orders in 1728, and about the close of 1729 was called from acting as his father's curate to perform the duties of his fellowship in person. At Oxford he found an association of students of which his brother Charles was a member. It was known by various nicknames, among which were the Holy Club, the Bible Moths, the Sacramentarians and the Methodists. It appears that all the association did at this time to earn these opprobrious epithets was to meet on Sunday evenings to read the Scriptures, and on other evenings to read secular literature. John Wesley joined this society, which gradually became exclusively religious in its object, and highly ascetic in its tone. Its members fasted twice and communicated once a week, visited prisons and the sick, and engaged frequently in prayer, meditation and self-examination. Among the members were Hervey and Whitefield. At the time John Wesley joined it the society numbered very few members, but it gradually increased, though it never became a large body. This induced him to decline his father's living at Epworth, that he might continue to exercise his influence at the university. During his residence at the university he became acquainted with Law, author of the 'Serious Call to the Unconverted,' who exercised much influence over him. In 1735 he accepted an invitation from General Oglethorpe to preach to the colonists of Georgia. He sailed on 10 Dec. with his brother Charles and a considerable body of Moravians. During his visit to the colony he paid his addresses to Sophia Hopkey, niece of the chief magistrate of Savannah, or rather, as the story is told, received her advances with favor, but ultimately declined to marry her. Miss Hopkey married a Mr. Williamson, and Wesley, without assigning a reason, refused to admit her to the communion. Her husband threatened legal proceedings, which were not enforced, but Wesley, on account of this event, left the colony, "shaking the

dust from his feet." He reached 1 Feb. 1738, just as Whitefield, unpreaching Methodism had made great headway, sailed for Georgia. At this time an event took place in the inner re Wesley. He was converted, according to his own account, about a quarter to 9 o'clock on the evening of 24 May 1738, at a meeting which he had gone very unwillingly to attend. He read Luther's 'Preface' to the Epistle to the Romans, which was being read. On 13 June he set out for Germany to visit Herrnhut. He met the Moravians at Zinzendorf at Marienborn, spent a fortnight there, and returned to England in the middle of September. Whitefield met him from Georgia soon after and became associated with Wesley. He began preaching near Bristol in the following month, and his example was soon followed by Wesley. On 11 Nov. 1739 Wesley first preached at the Foundry, a disused structure, employed by the government for casting ordnance. This he enlarged and improved until 1778 it remained the meeting place of the Methodists in London. Somewhat later he founded the "United Society," for the propagation of Methodism is generally dated from the beginning of this society.

In July 1740 Wesley separated from the Moravians on account of doctrinal differences, and soon afterward separated from Whitefield, without a permanent personal breach. He had now sole control of the religious movement, and adhered to him and he devoted his life without intermission to the propagation of its organization, in which he showed great practical skill and admirable method in his labors as an itinerant preacher. He had no permanent residence and devoted his journeys on account of his preaching. He would ride from 40 to 60 miles a day, and read or wrote during his journeys. He preached four or five times a day. He married in 1750 Mrs. Vazeille, a widow with five children, but his habits of life, which he had attempted to accommodate to his wife, led to an alienation, and they finally separated. Wesley held strongly to the principle of non-resistance, though not a believer in the apostasy of the Church of England. His collections were published by himself in 1771-72, and consisted of 10 volumes. But in these only a part of his literary output was included, his being of the most miscellaneous nature, including grammars, an English dictionary, biographies, manuals of history, and other works which together brought him in considerable money. In 1780 he commenced a quarterly paper, the 'Arminian Magazine,' which he edited until his death, and which after his death was continued in the 'Methodist Magazine.'

Against pre-Revolutionary troubles in America he directed 'A Calm Address to the Inhabitants of the American Colonies' (1775), 'A Calm Address to the Inhabitants of England' (1777), and 'A Calm Address' (1778). He also wrote several other addresses which are included in the 'Poetical Works of John and Charles Wesley' (1868-72). Wesley's bicentenary was celebrated in 1908. Consult the biographies by Hampson (1872), Moore (1872), Whitehead (1872), Moore (1824-25); Southey (1820), with Coleridge and 'Remarks' by Knox,

**SLEY, Samuel**, English clergyman t: b. Winterborne-Whitchurch, Dorset- 7 Dec. 1662; d. Epworth, Lincolnshire, l 1735. He was the father of Charles, id Samuel Wesley, Jr. Graduated from College, Oxford, in 1688, he was or- priest in 1690, became rector of South , Lincolnshire, in that year, and in 1695 orth in the same county. He wrote f Christ: An Heroic Poem' (1693); s's Hymn to the Creator' (1778); and orks, including the posthumous 'Disser- in Librum Jobi' (1735), etc. He is own by the two hymns to be found in ist hymn books, 'Behold the Saviour of d' and 'O, Thou, Who, When I Did in.'

**SLEY, Samuel**, English hymn-writer, the preceding: b. Spitalfields, London, 1691; d. Tiverton, 6 Nov. 1739. He was aster of Bundell's grammar school in n, in 1732-39. He did not embrace ism with his brothers, and wrote of it preading delusion." He was graduated hrist Church, Oxford, in 1715 and took . He is best known by his hymns in the ist hymn book. Among the titles of in- l volumes by him were 'Poems on Sev- casions' (1736); reprinted in 1808 and nd 'The Christian Poet' (1735). Con- erman, 'Life and Times' (1866).

**SLEYAN FEMALE COLLEGE**, Ga., an institution of higher learning en, founded in 1836 as the Georgia Fel- llege. It was the world's first chartered for women. It offers courses leading legrees B.A. and B.S. and there are be- conservatory of music and a sub-col- department. It is under Methodist ion and has about 500 students.

**SLEYAN METHODIST CONNEC- OF AMERICA**, known commonly as sleyan Methodist Church. See **METH- HURCHES OF THE WORLD.**

**SLEYAN METHODISTS.** See **ISM IN AMERICA.**

**SLEYAN UNIVERSITY**, located at own, Conn., was established in 1831 he auspices of the Methodist Episcopal eing the first educational institution ate grade established by that church nited States. The institution, how- is no organic relation with that church charter provides that it shall be abso- non-sectarian. The founders of the ty were offered the buildings of erican Literary, Scientific, and Military : if an endowment of \$40,000 were the gift was accepted and its condition

complied with. In 1868-78 the university's material resources were largely increased and several new buildings erected; and in 1903-16 several additional buildings were erected and the endowment funds doubled; in 1919-20 a campaign for \$3,000,000 for endowment and buildings was launched. Though founded and now maintained as a college for young men, women students were admitted from 1872 to 1912. The curriculum was thoroughly liberal- ized in 1873 and since that date the range and number of courses have been steadily extended. Thorough revisions of the curriculum were again made in 1907 and 1919. Under the present plan the university offers courses leading to the degrees of B.A., Ph.E. and B.S. In each course requirements for generalization, apply- ing in the first two years, provide that the stu- dent shall pursue introductory courses in a con- siderable range of departments, under specifi- cations varying for the several degrees. For the work of the last two years a concentration requirement prescribes that the student shall select the major portion of his studies in a closely related group of departments in order to acquire a considerable mastery of at least one field of study. Departmental honor work is also provided to encourage still greater thor- oughness and to develop the student's initia- tive. Courses of graduate study are provided leading to the degrees of M.A. and M.S. There are two fellowship and 38 scholarship endow- ments totaling nearly \$250,000, besides the scholarships established by the trustees for the remission of the tuition of students considered worthy of such assistance. The students main- tain various intercollegiate athletic teams be- sides carrying on a system of intramural ath- letics; the control of athletics being vested in an athletic council on which faculty, under- graduates and alumni are represented. They also maintain a semi-weekly paper, musical, dramatic and departmental clubs. There are a Commons Club and 11 Greek letter fraterni- ties, which have their own houses where many of the students live. The university has a campus of more than 40 acres on high ground at the western edge of the city and overlook- ing the Connecticut River. The buildings in- clude North College, New Dormitory and two smaller buildings used as dormitories; South College, the administration building, and the only one surviving from the old military acad- emy; Memorial Chapel in honor of the stu- dents who gave their lives in the Civil War; Rich Hall, containing the library (113,000 vol- umes, \$107,000 endowment for book pur- chases); the Van Vleck Observatory, with a 12-inch equatorial telescope, soon to be re- placed by an 18-inch one; Scott Laboratory of Physics; Judd Hall, which houses a valuable museum and the other departments of science; Willbur Fisk Hall, with recitation rooms; and the Fayerweather Gymnasium. Plans are being prepared for the erection of a chemistry laboratory in the near future. The productive endowment in 1919 was \$2,575,000, and the in- come was \$243,000. In the college year 1919- 20 the students numbered 595 and the faculty 52 in addition to the president, William Arnold Shanklin, LL.D.

**WESSEL**, wés'sèl, Johann (surnamed **GANSEFORT** (Dutch, **GOESEVORT**), Dutch theo-

logian: b. Groningen, 1419 or 1420; d. 1489. He passed the latter part of his life in retirement in his native country, part of the time in convents. He was a decided opponent of the scholastic theology and in intimate relations with some of the prominent humanists, as Agricola and Höck, yet in his own views leaned strongly toward mysticism. He regarded Christianity as something entirely spiritual, confined to a man's own heart and God. The Scriptures, according to him, are the living source of all true faith; the Church is based upon a compact; there is a general priesthood of the rational universe; faith is to be reposed only in an orthodox pope and not in every council; sin can be forgiven by none but God; excommunication has only an external influence; indulgences refer only to ecclesiastical penalties; the true satisfaction for sin is a life in God; and purgatory is nothing but the purifying influence of a longing after God. After his death some of his works were burned as heretical; his 'Farrago Rerum Theologicarum' was published with a preface by Luther (1522). The most complete edition of his works is that edited by Lydius (1617). Consult Muusling, 'Commentatio Historica-Theologica de Wesseli' (1831); Ullmann, 'Reformatoren vor der Reformation' (1847).

**WESSEX**, wēs'ēks, England, a former kingdom, from the 6th to the 9th century, one of the most important of the Saxon heptarchy, and that in which the other kingdoms were ultimately merged in the reign of Egbert in 827. Wessex, signifying West Saxons, as an independent unit of the heptarchy, occupied a territory now comprised in Dorset, Wilts and parts of Somerset and Hants. See **EGBERT**; **ENGLAND**.

**WEST, Andrew Fleming**, American philologist: b. Allegheny, Pa., 17 May 1853. He was graduated at Princeton University in 1874 and from 1883 he was professor of Latin there, while in 1901 he became also dean of the graduate school. He served for many years as chairman of the American School for Classical Studies at Rome, Italy; is a member of the National Institute of Arts and Letters; and in 1901 was president of the American Philological Association. He received the degree D.Litt. from Oxford University in 1902. Besides writing numerous articles on university and classical education in educational periodicals he edited Terrence's 'Andria' and 'Heautontimoroumenos' (1888); and 'The Philobiblon of Richard de Bury' (1889); and is author of 'A Life of Aluin' (1902); 'A Latin Grammar' (1902); 'American Liberal Education' (1907), etc.

**WEST, Benjamin**, American painter: b. Springfield, Chester County, Pa., 10 Oct. 1738; d. London, 11 March 1820. After some instruction from William Williams, a Philadelphia painter, and having painted 'The Death of Socrates' for a gunsmith, he established himself as a portrait painter at Philadelphia at five guineas per portrait and subsequently followed the same profession in New York. In July 1760 he visited Rome, whence he proceeded to Florence, Bologna, Venice and Parma. Returning to Rome, he painted 'Cimon and Iphigenia' and 'Angelica and Medora'. He was elected member of the academies of Florence,

Bologna and Parma, and, visiting England in 1763, was so well patronized that he determined to make it his future residence. He executed a historical painting of 'Agrippina Landing with the Ashes of Germanicus' for Drummond, archbishop of York, who introduced him to George III. The king became his steadfast patron and gave him commissions for many years. In 1772 he was made historical painter to the king, in 1790 surveyor of the royal pictures. He was one of four selected to draw up a plan of the Royal Academy, was one of the original members, and there exhibited his 'Death of General Wolfe' (now in the Grosvenor gallery, London) in 1771. In this canvas West departed from the custom of the artists of the day of giving the characters Greek or Roman costumes. Reynolds, who had endeavored to dissuade him, later said, 'I retract my objections. I foresee that this picture will not only become one of the most popular, but will occasion a revolution in art.' Woollett's plate after this work had the largest sale of any engraving of modern times. West painted a series of historical works for Windsor and for the chapel a series on the progress of revealed religion, divided into four series: antediluvian, patriarchal, Mosaic and prophetic. On the death of Reynolds in 1792 he was unanimously elected president of the Royal Academy. When George III became insane the order for painting the religious series was abruptly recalled and the pay stopped. West had finished 28 pictures and sketched the entire series. He afterward painted a number of religious and historical pictures on very large canvases. Among them may be noticed 'Christ Healing the Sick' (in the National Gallery), the 'Crucifixion', the 'Ascension' and 'Death on the Pale Horse' (Pennsylvania Academy). The 'Battle of La Hogue' is among the best of his historical pieces. West's pictures numbered about 400. They are chiefly of heroic size and display much inventive power and great skill in composition. But they are monotonously reddish-brown in coloring, and, despite their facility, lack spirit and imaginative value. His position in early American art has won for him a recognition somewhat in excess of his actual merit. Consult Galt, 'Life and Studies of Benjamin West' (1820); Tuckerman, 'Book of the Artists' (1867), and various dictionaries of art.

**WEST, James Harcourt**, American publisher and Unitarian clergyman: b. Melrose, Mass., 13 Jan. 1856. He was educated at Tufts Divinity School, was engaged in printing and as a newspaper correspondent in 1873-84, and in 1884-94 was minister in charge of various Unitarian and Congregational societies. He edited the *New Ideal Magazine* in Boston and was engaged as a publisher for some time. His writings include 'Holiday Idlesse and Poems' (1880); 'Uplifts of Heart and Mind' (1887); 'The Complete Life' (1888); 'Voices of Good—Poems of Freedom' (1892); 'Love with Love' (1894); 'Life Verses' (1894), etc.

**WEST, Oswald**, American publicist: b. near Guelph, Ontario, Canada, 20 July 1880. He was educated in the public schools and in 1899 to 1900 was clerk and paying teller of Ladd and Bush Bank of Salem, Ore. In 1900

he was paying teller of the First National Bank of Astoria, Ore.; in 1903-07 was State land agent of Oregon and in 1907-10 member of the Oregon Railroad Commission. He was governor of Oregon from 1911 to 1915, resuming his law practice at Portland. In 1918 he was Democratic nominee for the United States Senate, but failed of election.

**WEST, Paul**, American journalist and playwright: b. Boston, 26 Jan. 1871. He graduated from Peekskill Military Academy in 1888 and soon engaged in literary work. Of his musical comedies 'The White Hen' is perhaps the most popular. He is a prolific writer of songs, short poems, magazine articles and newspaper stories. The files of *Everybody's*, *Cosmopolitan* and *Munsey's* magazines contain a vast amount from his pen. In 1898 he made a permanent connection with the *New York World*. He wrote 'The Love Waltz,' 'At the Waldorf,' 'Birdland,' 'The Twentieth Century,' 'The Song Shop,' 'Short Letters of a Small Boy,' etc.

**WEST, Thomas, BARON DELAWARE OF DELAWARE**, English colonial governor of Virginia: b. 9 July 1577; d. at sea off the Atlantic Coast of America, 7 June 1618. He was educated at Queen's College, Oxford, in 1597 was returned to Parliament for Lymington, fought in the Low Countries and in Ireland, in 1609 became a member of the council of the Virginia Company and in 1610 was made first governor and captain-general for life. On 10 June he arrived at Jamestown, where he soon restored order and comparative prosperity. He established a post at Riquotau (now Hampton), and built two forts. At the time of his coming want and mismanagement had almost compelled the settlement to disperse. By June 1611 he was again in England, where he printed a very favorable report as 'The Relation of the Right Honorable the Lord De-La-Warre.' In March 1618 he set sail once more for Virginia, but he died on the voyage. Consult Neill, 'The Early Settlement of Virginia' (1878); 'Proceedings of the Virginia Company' (Virginia Hist. Soc., 1888).

**WEST (THE) AS A FACTOR IN AMERICAN POLITICS.** The great West rather than the Atlantic Coast is the true point of view in American history—in which the controlling influence of the frontier is the strongest factor. The West has been America's greatest problem—the problem of expansion by winning a series of frontiers, the last of which marked the completion of the conquest of the continent. Its opportunity of new lands, its presentation of new lessons and duties, its training in adaptation to new conditions and in the creation of new institutions to serve new needs, and its new optimistic visions and ideals, enabled Americans to achieve a larger conception of American destiny and democracy. It has been a constructive force of the highest significance in the evolution and adaptation of political organs in response to changed environment. In the face of Eastern opposition which feared its influence might control the destiny of the republic, its forest philosophy became the basis of a revised American democracy. James Bryce in his 'American Commonwealth' declared that 'the West is the most American part of America.'

The earliest influence of the West as a factor in American politics appeared in the 'con-

tests' of the interior rural element of the colonies against the older settlements nearer the coast, and later reappeared in each political division in political contests of the back-country frontier against the dominating tidewater regions which long retained a predominant influence in the State governments. Among the early illustrations of frontier influence in Virginia were Bacon's rebellion of 1676 and the later increase of small farmer landholders of the interior in the administration of Governor Spotswood by accessions of immigrants and indentured servants, resulting in complaints of the tidewater planters. A later illustration was the War of the Regulation in the back counties of North-Carolina in 1771.

Increasing in importance by settlements made in opposition to the king's proclamation line, the western frontier became the rear guard of the Revolution and the advance guard of the republic, influencing the negotiations of 1782-83 which established the western boundary at the Mississippi. A large western territory, whose ownership was a source of both diplomatic and interstate controversy, fortunately (through treaty and subsequent state cessions) became national public domain, the first property of the new nation, constituting a common interest and the first tangible sign of national unity.

At the close of the Revolution the frontier conflicts with the east coast were especially noticeable in western Pennsylvania, western Virginia and in the transmontane territory of North Carolina which after the Revolution demanded independent statehood, appealing to the record of their conquest of the wilderness from savagery to civilization. In Massachusetts the contest was marked in the significant movement known as Shay's Rebellion of 1796 which awakened the apprehension of conservative men in the constitutional convention and resulted in restrictions on suffrage which were removed in time only by the development of the interior regions.

In the new constitution frontier influence appeared in the liberal territorial relations and equality of statehood for western communities whose desire for political autonomy had been expressed in various efforts before Congress obtained full control of western lands claimed by the various tidewater State governments.

Jefferson, born on the frontier region of his day, became the prophet of democracy, and, by a series of legislative measures in Virginia, prepared the way for the larger influence and dominance of the interior class—which, however, was only slowly attained by the slow but steady tide of settlements farther and farther toward the interior.

After the Revolution the advancing frontier of transmontane settlements marked the growth of a new and greater West more influential in the nation's destiny. By 1800 the trans-Appalachian region had become the home of about one-tenth of the population. In the decade before 1800 it exercised an important influence in foreign relations in connection with the foreign plans to acquire control of the Mississippi Valley and the Great Lakes. In the decade and a half after 1800 it became a more powerful influence, notably in the purchase of Louisiana in 1803 and the War of 1812 which insured new areas for advance in three directions.

Under its early vision of manifest destiny it successfully resisted the obstacles which checked or restricted its advance. From its early position on the Ohio Valley, as the flying column of the nation, it served as an entering wedge to the possession of the Mississippi Valley. The acquisition of Louisiana, dictated by frontier needs, marked the downfall of a policy of strict construction and furnished a new area for national legislation. It furnished new opportunities for the rise of younger commonwealths which shook the older ones out of their self-centred life, and for the rise of new problems which broadened the processes of nationalization and greatly influenced questions of politics.

In turning the scale in favor of the War of 1812 the West gave voice to the newer nationality of the newer States. Meantime, the possibilities of its great historic waterway furnished the incentive for Fulton's successful invention of the steamboat.

The steady increase of westward extension and the consequent increase of western ideals, between 1800 and 1820, alarmed the established classes of the East who—already sighting a new problem in the labor populations of its cities which began to assert a determination to share in government—saw in the democratic tendencies, of the newly-created frontier States, contagious influences which were already blowing from the West to liberalize the more conservative constitutions of the East.

In the years following the War of 1812, aided by the revolutionizing effect of steam navigation on transportation, and with its practical backwoods ideal of democracy, the phenomenal rise of the new West was the most significant fact in American history. For the half decade after 1815 it furnished a new State each year, carrying the wedge of settlement up the Missouri to its bend at the junction with Kansas on the edge of the traditional "American desert" where the apex of the frontier lines halted for almost three decades awaiting the advance of the right and left flanks which the apex had so far outdistanced.

Thus, by 1820, the West had nine States whose achievement in the extension of more liberal political ideas in American democracy reacted upon the older and more conservative States of the East, both by example and by actual pressure from loss of population through emigration resulting from the more attractive conditions of political equality in the West.

On its advancing frontier depended largely the growth of nationalism and the evolution of American political institutions. Its economic influences after 1815 made it a nationalizing force in the field of domestic policy, as shown in a series of congressional legislative acts which increased the power of the Federal government. In legislative action and in the economic and social characteristics, it stood in opposition to the sectionalism of the coast. In the problems of internal development and economic legislation, in the period between 1815 and 1860, it held the balance of power and set the course of national progress.

By 1822 it had a congressional voting power which gave to its interests and ideals a powerful if not a controlling voice in national councils, and with its strong nationalistic feeling it had a self-confidence untroubled by any doubts of its capacity to rule. Increasingly reacting

upon the older sections, by its competition and attraction for settlers, it gradually became a dominant force upon the economic and political life of the nation. Its rising commerce and demand for eastern manufactures attracted the attention of eastern ports (New York, Philadelphia, Boston and others) which entered a race of competition for control of trade through development of State systems of internal improvements in transportation—a rivalry for access to new tributary spheres of influence whose latest phase appeared in railroad legislation.

The result of its influence was liberal construction of the constitution and a larger nationality. Its nationalizing tendency transformed the democracy of Jefferson into the national republicanism of Monroe and later into a new democracy which marked the triumph of the frontier as an effective force in the nation.

Finally in 1829, it elected to the Presidency its typical Scotch-Irish representative, Andrew Jackson, who had become the hero of the whole West in the War of 1812 and by subsequent Indian fighting, and who especially became the mouthpiece of the Western popular will in his assaults upon the national bank as an engine of aristocracy and in his denunciation of nullification in South Carolina. Although its triumph marked the end of an old era of trained statesmen, and a new era of the Spoils system in politics and of lax financial integrity (illustrated by wild-cat banking), it prepared the way for a broader and better democracy whose first great representative was the pioneer rail-splitter, Abraham Lincoln of the old Northwest.

From 1816 to 1832, under the principle of the American system, it turned the scale in favor of protective tariff bills. Under Jackson its characteristic financial policy was expressed in the opposition to the United States Bank.

Its persistent influence induced Congress to abandon its earlier policy of forbidding settlements by "squatters" on unsurveyed lands and periodically to enact emergency indemnifying pre-emption acts; and, finally, in 1841, it succeeded in securing a general pre-emption law—the forerunner of the later Homestead Act of 1862.

Meantime through experience and struggle the West caught the vision of continental destiny. The call of a farther West stimulated new explorations, resulting in continental trails, new problems of long distance government for Oregon and a new California, and new Indian problems.

In the decade after 1840, its advancing frontier influenced diplomatic relations in regard to Texas, Oregon and California, and bore a close relation to the political contests in regard to slavery.

Fostered by the liberal Federal policy which sold land cheaply for "squatters" homes and gave it freely to aid the construction of roads and canals, it received new impetus from the picturesque and spectacular rush to California which so rapidly grew to Statehood and precipitated new problems in American politics.

In 1848 its political influence aided the Democrat nomination of Cass for the Presidency, and also the nomination of Van Buren by the newly-formed Free Soil party. In 1860 it furnished for the Presidency two candidates—Douglas, whose support was in the border zone, and Lincoln, whose strength was in the north-

e. After 1860, its economic and political continued to increase.

ough early regarded as the child of the the Middle West of the Ohio Valley with its commerce gradually diverted by es and by rail to the East, became grad- ss dependent upon the South and disap- the hopes of Calhoun and others who l too late to control it, politically as well mercially, by the construction of a rail- om Charleston via Chattanooga to west- ninals at Cincinnati and at Mobile.

In the Populist move- a later phase of discontent especially ent in States of the later frontier, the xpressed a large faith in the power of ional government to cure various evils ernment control or ownership of public , expansion of national currency and nent regulation of other economic conf life in the interest of the common

1890 its political influence was increased

by a group of six new frontier States (North Dakota, South Dakota, Montana, Washington, Idaho and Wyoming) in proximity to the new railroads of the farther Northwest, and it especially appeared as a factor in the revolutionizing of the Democratic party under W. J. Bryan in the election of 1896. The failure of the Western political revolution was due in large part to the older States of the Middle West which, having become adjusted to conditions, had ceased to be discontented, were no longer political enemies of the East and refused to favor free silver. Later, in 1912, after leading his party to defeat three times, Mr. Bryan, as the champion of western interests, reached the height of his spectacular party leadership in the strategy of the Democrat convention at Baltimore which resulted in the nomination of Woodrow Wilson on a platform acceptable to the West. The West was thus the most potent factor in Wilson's nomination, and four years later it sent him to the White House a second time; California was the pivotal State in that election and while it returned Hiram Johnson, a Progressive Republican, to the Senate, it chose Democratic presidential electors and their votes gave President Wilson a majority in the Electoral College. In 1898, after the extinction of the last continental frontier, the West found for its expansive spirit new expression in the over-seas expansion which marked America's maturity as a world power; and later, with its discontent relieved by a tide of prosperity, it exerted a new national influence illustrated in the political "insurgency" movement and in the subsequent Progressive movement for direct popular government and political control of economic life.

In its latest development the West, in the face of new conditions, was forced to abandon its idea of individualism in favor of co-operation and governmental activity under the powerful arm of national authority—which was regarded as necessary for the construction of expensive irrigation works for utilization of the arid lands, and to protect public resources from absorption by the captains of industry.

In the recent World War, the West, in spite of its earlier indifference and its strongly anti-American and pacifist areas, was awakened by the stirring speeches of Roosevelt and President Wilson, and proved loyal to duty in a great cause.

The frontier West exerted a useful influence in producing in American life a renewal of the principles of free government upon which the republic was founded, in keeping alive the principles of democracy in the midst of great accumulations of wealth, in widening the scope of the national government in meeting popular needs for "public improvements," in determining a liberal public land policy based on the idea of homesteads for a democracy of small landholders, in establishing systems of free education culminating in co-educational State universities and in furnishing a reason for the maintenance of a small defensive force of national troops. It provided the way to the fortunate erection of logical and permanent boundaries of the republic at the borders of the Pacific. After the achievement of continental occupation it continued the movement for extension of American influence by advocacy of a vigorous foreign policy, a revived merchant marine and interoceanic canal. Its latest

influence appears in the recent movements for extension of popular participation in government through direct primaries, initiative and referendum and woman suffrage—movements widely popularized by the sympathetic attitude of President Roosevelt who understood the spirit of the West by a period of residence and by close study of its history and problems.

*Professor of History and Political Science,  
West Virginia University.*

**WEST ALLIS, Wis.**, city in Milwaukee County, on the eastern outskirts of Milwaukee, and on the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern railroads. It is an industrial suburb of Milwaukee and manufactures automobiles, trucks, engines, machinery, steel castings, tools and woodwork. Pop. 6,645.

**WEST BAY CITY, Mich.** See BAY CITY.

**WEST BEND, Wis.**, city, county-seat of Washington County, on the Milwaukee River, and on the Chicago and Northwestern Railroad, about 35 miles north of Milwaukee. It is in an agricultural and stock-raising region. The chief manufactures are flour, wagons, harnesses, spokes, hubs, aluminum ware and pocket-books. It has grain elevators, machine shops, a foundry and a creamery. There are six churches, public and parish schools and one bank. Pop. about 2,462.

**WEST BERWICK, Pa.**, borough in Columbia County, on the Susquehanna River, a suburb of Berwick, 24 miles from Wilkes-Barre, and on the Delaware, Lackawanna and Western Railroad. There is a car and foundry plant here. Pop. about 5,512.

**WEST BLOCTON, Ala.**, town in Bibb County, 40 miles southwest of Birmingham, on the Louisville and Nashville, the Mobile and Ohio and the Southern railroads. Its principal industries are coal mining and lumbering. It has a savings bank, four public schools and municipal waterworks. The value of its taxable property is \$500,000. The receipts and expenses average \$6,000 annually. The government is vested in a board of aldermen. Pop. 4,000.

**WEST BROMWICH, Brum'ich, England**, a manufacturing town in Staffordshire, between Wednesbury and Birmingham. The principal buildings include the town-hall with a massive tower; a number of fine modern churches; several chapels of different denominations; public schools; an institute, art and technical schools, a free library and a hospital. There is a fine public park. West Bromwich has a share in the mining and manufacturing industries of this busy district and has grown largely of late years, carrying on the manufacture of iron goods of various kinds, smelting, brass-foundry, etc. It was an important centre of arms manufacture during the World War. Pop. 70,000.

**WEST CHESTER, Pa.**, borough, county-seat of Chester County, on the Wilmington and Baltimore and the Philadelphia railroads, about 27 miles west of Philadelphia. It was originally called Turk's Head, but in 1786 the county was divided and the name was changed to West Chester when it was made the county-seat. The new county was called Delaware, but it retained the old county-seat, Chester. West Chester has a number of manufacturing establishments, among which are carriage factories, creameries, gas engine works, sash and door factories and manufactories of hosiery, umbrella tags and wood products. The principal public buildings are the Chester County Hospital, the county courthouse, prison, theatres, a large convent and the municipal buildings. Marshall square contains a soldiers' monument and a handsome fountain. The educational institutions are a State normal school, Villa Maria Academy, Friends' Select School, The Darlington Seminary, West Chester Business College, a public high school established in 1865, public and parish schools, a public library, a law library and three school libraries. There are eight banks and a daily newspaper. Pop. 14,000.

**WEST FARNHAM, Canada.** See FARNHAM.

**WEST FLORIDA**, that part of the English possessions in Florida in 1763 west of the Apalachicola River, bounded on the west by Lake Pontchartrain, the Mississippi and Lake Maurepas and on the north by the 31st parallel of latitude. In 1763 it was made into a separate administration district. The governor had the power of convening general assemblies. Laws were made by the governor with the approval of an advisory council and the general assembly. During the Revolutionary War West Florida sided with the British Crown; in 1780 it was attacked by the Spaniards and by 1782 the British were driven out. By the Treaty of 1783, in which England acknowledged the independence of the United States, Spain was permitted to retain Florida but a secret clause of the treaty made the southern boundary of the United States the 31st parallel instead of the line 32° 28' as had been fixed in February 1764. Spain refused to evacuate the portion between the two lines and a bitter dispute followed with the United States which nearly resulted in hostilities. Finally Pinckney succeeded in negotiating a treaty by the terms of which the 31st parallel was acknowledged as the boundary of West Florida, while the United States assumed all claims against

by citizens of Georgia for spoliation, etc. disagreement with Spain developed in when the United States claimed that part of Florida west of the Perdido River as of the Louisiana Territory which it had purchased from France. The dispute did not until in 1810 the part of West Florida between the Perdido and the Mississippi declared its independence of Spain and became the Republic of West Florida. This territory was seized by the United States and order was restored to the district. The part west of Pearl River became part of the Territory of Orleans. In 1812 West Florida was added to Louisiana and the part between the Perdido and Pearl rivers was annexed to the Territory of Mississippi. In 1812 English troops had their base in Florida in their operations against the United States. Jackson drove them out and took Pensacola. During the Seminole War, Jackson again occupied a part of Florida. The province was administered by United States officials appointed by Jackson until 1819 when it was returned to Spain. In 1819-21 negotiations for the purchase of Florida were undertaken by the government of the United States. On 17 July 1821 Spain gave up all her claims to the United States and the portion of West Florida east of the Perdido was incorporated in the Territory of Florida. Consult Fairbanks, G. R., 'History of Florida' (1871); Fuller, H. B., 'Purchase of Florida' (1906); Green, E. L., 'History of Florida' (1898).

**WEST HAMMOND**, Ill., city in Cook County, on the Calumet River, a southeastern suburb of Chicago. It has a hospital and a school and there are glue factories. Pop. 4,808.

**WEST HARTFORD**, Conn., town in Hartford County, on the southwestern outskirts of Hartford. It has an orphanage, an old people's home, a high school and two parks. The Mount Carmel Seminary is situated here, as is the Augustine Normal School. The public square is a memorial to Noah Webster, who was born here. The town is a shipping centre for the surrounding district, which is interested in agriculture, culture, dairying and truck gardening. Pop. 4,808.

**WEST HAVEN**, Conn., village and former town in New Haven County, now a part of the town of West Haven; it is situated on Long Island Sound and New Haven Harbor, on the eastern limits of New Haven and on the York, New Haven and Hartford Railroad. It is principally a residential town, has a high school, two sanatoria, the county hospital, a lunatic asylum, an inebriates' home and the Florence Crittenden Home. There are numerous factories of automobiles, safes and fertilizers. Pop. 8,543.

**WEST HAZLETON**, Pa., borough in Luzerne County, a suburb of Hazleton, 22 miles west of Wilkes-Barre, on the Pennsylvania Railroad and on the Wilkes-Barre and Scranton Electric Railroad. Its chief industry is coal mining. There are coal mines in the town. Pop. 4,715.

**WEST HOBOKEN**, N. J., town in Hudson County, enjoying the distinction of being the largest community under town government in the United States, adjoining Hoboken and Jersey City, about one mile from the Hoboken ferry on the Hudson River. It is on elevated land which rises somewhat abruptly from the land along the river at Hoboken. It is a residence place for workers in New Jersey and New York City, and has considerable local manufacturing, especially silk-mills, embroidery works, rubber and leather works. In 1918 the town had 250 manufacturing establishments, which were capitalized for about \$6,000,000, the silk factories alone being capitalized for \$1,000,000. The yearly production is estimated as \$7,000,000. The principal public buildings are Saint Michael's Monastery (Passionist Fathers) and the Dominican Convent. The educational institutions are a theological school at the monastery for their own members, a high school established in 1897, public elementary schools and two large parish schools. There are prosperous banks and two newspapers. Pop. 38,776.

**WEST HOMESTEAD**, Pa., borough in Allegheny County, on the south bank of the Monongahela River, a suburb of Homestead, opposite the eastern portion of Pittsburgh and on the Baltimore and Ohio Railroad. There are steel-mills, brickworks and manufactories of machinery, axles and car wheels. Pop. 3,009.

**WEST HOUGHTON**, hō'ton, England, a township in Lancashire, five miles west-southwest of Bolton, with manufactures of silk and cotton and coal-mining.

**WEST INDIA ISLANDS** or **WEST INDIES**. The archipelago that includes the Great and Lesser Antilles and the Bahamas has a total land area of about 92,000 square miles—more than twice the size of Pennsylvania; the islands are, however, dispersed far and wide over a region continental in size, which extends from lat. 10° N. to 28° N. and from long. 58° W. beyond 85° W. For the geographical subdivisions of the main groups, see ANTILLES and BAHAMAS; for the geologic relations of some of them to the mainland portions of the Antillean continent, see CENTRAL AMERICA and CARIBBEAN SEA; and for the characteristic features of the Great Antilles see the separate articles CUBA, etc.

To pass from a western to an eastern point in this archipelago, one may be obliged to sail about 2,000 miles; and to pass from its northernmost to its southernmost island one must sail more than 1,500 miles. This wide dispersion is the fact which should be first noted. The next step is to realize fully the disjunctive political conditions, the results of the distribution of the islands among a number of competing nations. Let us now consider the political subdivisions. The British possessions are: The Bahamas, including 20 inhabited and many desert islands; Jamaica, with Turks and Caicos Islands, etc.; Windward Islands, including Grenada (the governor's residence), Saint Lucia, Saint Vincent and the Grenadines; Barbados, east of the Windward Islands; Trinidad and Tobago, near the South American coast; and the Leeward Islands, comprising Antigua

(with Barbuda and Redonda), the Virgin Islands, Saint Kitts (Saint Christopher), Nevis, Anguilla, Dominica and Montserrat. The total area of the British West India islands is 12,631 square miles (4,431 in Jamaica and its dependent smaller islands). The exchange of ratifications of a treaty between Denmark and the United States on 17 January 1917 had the effect of transferring to the latter the small islands of Saint Thomas, Saint Croix or Santa Cruz and Saint John, with a total area of 139 square miles and a total population of about 27,000. The amount paid by the United States for these Danish islands (the possession of which insures substantial control of the Virgin Passage through the Lesser Antilles) was \$25,000,000. French possessions are Guadeloupe and its dependencies, and Martinique, their total area being about 1,073 square miles and total population about 406,430, combined exports about \$9,400,000 and imports about \$8,300,000. A French and Dutch possession is the island of Saint Martin, 38 square miles in area, of which it has been well said: "The political complexion of Saint Martin is peculiar. Seventeen square miles of the northern section belong to France and the rest to Holland, while the settlers, largely blacks, are principally British, who outnumber both the Dutch and French. About 3,000 of the inhabitants are in the French portion of the island, and 5,000 in the Dutch" (Hill's *Cuba and Porto Rico*, etc.); furthermore, "each maintains an administrative force as large as that of the State of Texas." The Dutch possessions—fragments on opposite sides of the Caribbean Sea—are the islands of Curaçao, Aruba, Bonaire or Buen Ayre, Saint Eustache, Saba and part of Saint Martin, as just stated. Venezuelan possessions are some of the islands, not appropriated by the English or Dutch, in the east-and-west line between Trinidad and the Gulf of Maracaibo. The list is completed by adding Cuba and the Isle of Pines, a republic, subject in certain matters to the control of the United States; Porto Rico, with the small neighboring islands, a possession of the United States; and Santo Domingo, or Haiti, with adjacent small islands. Mr. Hill's observation in 1898 was that, "As we sail down the eastern islands, hardly a score in number . . . we find five foreign flags and no less than a dozen distinct colonial governments . . . with no shadow of federation between them, or even co-operation of any kind." For example, Dominica, though lying between Guadeloupe and Martinique, and within sight of both, is commercially farther from them than from England, because it is cut off from the French neighbors by tariff and quarantine laws.

Edwards, in his history of the British West Indies, says that the "state of the population" in the islands which he described in 1791 was as follows: Whites, 65,305, and blacks, 455,684. The proportion of Caucasians has decreased owing to causes mentioned in the articles JAMAICA, etc. The principal attraction of these islands for immigrants from Great Britain and white residents (what there was left of it after the manumission of the slaves which was completed in 1838) ceased when the cane-sugar industry became unprofitable. To speak of this as a new or temporary crisis is absurd: it is an

old story. Anthony Trollope, when he wrote of 'The West Indies and the Spanish Main' in 1859, said: "That Jamaica was a land of wealth, rivaling the East in its means of riches, nay, exceeding it as a market for capital, as a place in which money might be turned; and that it now is a spot on the earth almost more poverty-stricken than any other—so much is known almost to all men." Now, such distress, long-endured and notorious, has more or less discouraged immigration, commerce and other influences that make for uniformity in population, manners and usages. Mr. Hill's assertion that "each of these islands is breeding a different species of mankind" may seem at first view rather extravagant; but when we reflect that geography, politics and poverty combine to isolate and segregate those communities, we shall regard the following statements as decidedly moderate: "The West Indian people represent many original stocks, which have developed variations of habits and customs in their New World environment. They are practically divisible into three great races, the white, colored and black, modified by Spanish, English and French civilizations." The influence of the aboriginal stock should by no means be overlooked (see CARIB, PORTO RICO, CUBA, etc.), nor can we regard that of the Dutch and Danes as a negligible quantity. Mr. Hill writes: "In the countries in which the French race habit has been implanted, Haiti, Martinique and Guadeloupe, there has resulted a more complete elimination of the Caucasian type than in either the English or (until 1898) Spanish islands. The black races of the West Indies and their habits are most interesting studies. Gathered as they were from numerous tribes of Africa, and settled upon the different islands, they naturally show not only differences in inherited qualities, but in those habits acquired from different masters for which the African is noted. Thus there are English, French, Spanish, Irish, Scotch and Dutch negroes in the various islands." Again, differences in topography, soils, flora and climate, which, as we have said, require separate studies, have been summarized most intelligently by Mr. Hill, who writes: "These islands, far from being alike in natural features and economic possibilities, present great extremes. Some are low, flat rocks barely peeping above the sea; others gigantic peaks rising straight to the clouds, which perpetually envelop their summits; others are combinations of flat and rugose types. Some present every feature of relief configuration that can be found within a continental area—mountains, plains, valleys, lakes; some are made up entirely of glaring white coral sand or red rock; others are entirely composed of black volcanic rock, and still others are a combination of many kinds of rocks. Many are as arid as a western desert and void of running streams, and others have a most fertile soil, cut by a hundred picturesque streams of living water, and bathed in perpetual mist and daily rainfall. Some are bordered only with the fringing salt-water plants or covered with thorny coriaceous vegetation; others are a tangled mass of palms, ferns and thousands of delicate, moisture-loving plants which overwhelm the beholder with their luxuriance and color. Some are without human inhabitants; others are among the most

populated portions of the world" (for Barbados: 1,120 to the square mile). Diverse configuration produces climatic effects, and each kind of rock weathers into peculiar soil. . . . Some of these islands, in possibilities of a diversified agriculture and climatic condition, are adapted to higher civilization, and others, either through sterility or want of relief, are capable of supporting inferior races." The total number of inhabitants is approximately 6,000,000.

Volcanic eruptions are fortunately confined to Martinique and Saint Vincent, although they occur everywhere in the Lesser Antilles as evidence of the activity of mighty volcanic forces in times not vastly remote, geologically speaking—for the submerged Antillean coasts are fairly bordered with these much later formations that form the eastern volcanic chain.

The climate is not only very agreeable in the winter months but also decidedly healthful, and in all parts of the archipelago, especially in the northern part, it deserves such mention at all seasons. The rainy half-year begins as a rule, in June and (with an interval of clear weather about August or September) extends to the end of December. From June to June, then, almost ideal conditions prevail in the northern and central islands as well as the southern. The northeast trade-winds are most beneficial in their ministrations to comfort and health during January, February and March; in April, September and October, on the southern coast, there are occasional hurricanes—

and, there are occasional hurricanes—of great violence.

**History.**—The history of the West Indies dates from the discovery of Columbus on October 12, 1492. The royal standard of Spain was then unfurled on an island known to the natives as Guanahani, but named by Columbus, very gratefully, San Salvador. Sir Christopher Columbus, Sir Francis Drake, Sir Walter Raleigh and others have succeeded in exploring the scene of this first landfall as well as the only West Indian island which is still a "minute particular" answers the definition (by the discoverer himself) of San Salvador or Guanahani. Greatest periods and events in West Indian history are these and these: The period of Elizabethan adventures of the seamen whose achievements in these days helped to immortalize the names of Drake and Walter Raleigh and John Rolfe; the period of the buccancers and of the privateers; the period of the great discoveries of Christopher Columbus and of Sir Francis Drake; that most important, decisive period for British naval and colonial enterprise, the period of the brilliant success in the engagement of the French fleet under de Grasse in the period or episode, of Nelson, "who is his bride in Nevis," writes Aspinwall, "and the capture of the French ship that now lies in Portsmouth harbor, pursued Villeneuve to the West Indies and back, a fitting finale to the battle of Trafalgar"; the period of the manumission of the slaves, which was effected in the British West Indies, by long and arduous financial distress bravely met (about 1830 to the end of the century); and finally the period characterized by that radical movement in the conditions of agricultural industry and foreign trade which we observe to-day. The author of "Cape Cod Interests of the United States" (see bibliography) says: "With European colonies

in the West Indies, the development of our trade relations is hampered by a number of causes. . . . Lack of transportation lines hinders exchange with some of the colonies. The subsidized steamship line between the British West Indian ports and Canada drains off some of their trade in that direction. The preferential tariff in force since 1913 affects our trade adversely. The policy of France, also, is to shape her tariffs in the West Indies to shut out the sending of colonial goods to foreign countries and to insure the home market a monopoly of imports where possible. Banking houses, especially when they have government connections, may be used to make the trade run on national lines. The banks in the French West Indies, it is reported, charge 3 per cent in addition to the regular rate of exchange on all payments made through New York. In some of the colonies branches of commercial houses in the home country are established. They buy only for their principals. Furthermore there is a French reciprocity treaty with Haiti which operates to their advantage. Beside these efforts on the part of other governments or their nationals to promote their foreign commerce, our foreign trade is, of course, affected by our tariff." In causes such as these must be sought the explanation of the circumstance that the commerce of the United States expands less readily in the European dependencies than in the Latin American republics of the West Indies. The increase noted in exports from the United States to the British West Indies during the period 1902-14 was 36 per cent; to the Dutch West Indies 43 per cent; to the French West Indies 23 per cent. The increases in the imports into the United States during the same period were: From the British West Indies 27 per cent; from the Dutch West Indies 147 per cent; from the French West Indies 175 per cent. A fact not to be overlooked in this connection is that the British West Indies are as a reward of perseverance, with courage and enterprise, in the face of adverse circumstances, recovering from the long period of depression to which we have referred. Sir Charles Lucas, head of the West Indian Department of the British Colonial Office, has said that while the 19th century had witnessed their distress the 20th would be the century of their regeneration; and Mr. Asquith has given high authority to the statement that they have grown to be independent of financial assistance from Imperial funds. The financial situation, the natural resources, foreign commerce, etc., of the Greater Antilles are subjects of special studies in the articles CUBA, DOMINICAN REPUBLIC, HAITI, JAMAICA and PORTO RICO.

A., 'The Early History of Cuba' (New York 1916).

**WEST INDIA TRADE, 1783-1833.** When the United States of America declared and won their independence they lost simultaneously the unrestricted trade with those islands in the Antilles which were under the British flag. The Treaty of 1783 made no provisions for the commerce of this region and in the same year trade into and out of the British West Indies was restricted to British vessels by Orders in Council. In 1814 efforts were made in the United States to secure a part of this trade through a modification of the British restrictions; nothing came of these efforts and in 1818 Congress retaliated by closing American ports to British ships from the West Indies. A few years later, in 1822, the English Parliament modified the restrictions, but placed a differential duty in favor of British products. The policy of retaliation was again resorted to in order to have American goods placed on the same footing as British goods. Smuggling was resorted to and a diplomatic deadlock ensued. In 1830 the retaliatory laws of the United States were repealed and British vessels were thereafter admitted on the same terms as American vessels clearing from the same ports. Britain thereupon granted reciprocal privileges. Consult Moore, J. B., 'American Diplomacy' (1905).

**WEST MINNEAPOLIS, Minn.,** village in Hennepin County, on the southwestern limits of Minneapolis. There are manufactories of sewer pipes, threshing machinery and steel springs. Pop. 3,022.

**WEST NEWTON, Pa.,** borough in Westmoreland County on Youghiogheny River, 30 miles southeast of Pittsburgh on the Pittsburgh and Lake Erie and the Baltimore and Ohio railroads. Its principal industries include the manufacture of boilers and radiators. Pop. 2,880.

**WEST NEW YORK, N. J.,** town in Hudson County, on the Hudson River, north of Weehawken and connected with New York by a ferry to 42d street. It has a water front one mile in length and has docks and grain elevators. It is chiefly an industrial community, and manufactures include pianos, silks, textiles, rubber goods, cottonseed oil, sugar, buttons, braid and other products. Pop. 22,943.

**WEST ORANGE, N. J.,** town in Essex County, 13 miles west of New York and five miles northwest of Newark, on the Erie Rail-

road. It is built at the base and on the slope of Orange Mountain, and has fine parks and many beautiful residences. Eagle Rock, with its elevation of 650 feet, affords a splendid view. There are manufactures of phonographs, felt hats, lawn mowers and other articles. The place was organized as a township under the name of Fairmount in 1862, was renamed West Orange in 1863, and was incorporated as a town in 1890. Pop. 13,610.

**WEST PARK, Ohio,** village in Cuyahoga County, on the outskirts of Cleveland and on the Lake shore and Michigan Southern and the Cleveland, Cincinnati, Chicago and Saint Louis railroads. It is a residential suburb of Cleveland. Pop. 3,179.

**WEST PITTSTON, Pa.,** borough in Luzerne County, on the Susquehanna River, and on the Delaware Lackawanna and Western Railroad, opposite Pittston. Two bridges span the river and connect the borough with the city. It is mainly a residential borough, many of the men who do business in Pittston (q.v.) have their homes in West Pittston. Pop. about 6,848.

**WEST PLAINS, Mo.,** city, county-seat of Howell County, on the Saint Louis and San Francisco Railroad, about 125 miles south of Jefferson City. It is the centre and shipping point of a region where there are farming, fruit-growing and lumbering interests. Large quantities of apples, grapes, dairy and farm and lumber products are freighted from this locality. There are two State banks, one daily and four weekly newspapers. The city has adopted the commission form of government. Pop. 2,914.

**WEST POINT, Ga.,** city in Troup County, on the Chattahoochee River, and on the Atlanta and West Point and the Western of Alabama railroads, about 85 miles southwest of Atlanta. It is in an agricultural region in which cotton is one of the chief products. It has cotton gins, cottonseed-oil mills, cotton factories, an iron foundry and a machine shop. During part of the Civil War it was a supply depot for the Confederate army. Pop. about 1,906.

**WEST POINT, Miss.,** town, county-seat of Clay County, on the Mobile and Ohio, the Southern, and the Illinois Central railroads, about 16 miles northwest of Columbus. It was founded in 1857 and is in an agricultural region in which cotton is one of the principal products. The chief industrial establishments are wagon and carriage factories, foundries, machine shops, brick and tile works, lumber mills, sash, door and blind factories, milling and ginning establishment and ice factories. It has six churches, the Southern Female College, Carnegie Library and elementary schools. There is a national bank and a daily newspaper. Pop. about 4,864.

**WEST POINT, Neb.,** town, county-seat of Cuming County, on the Elkhorn River, and on the Fremont, Elkhorn and Missouri Valley Railroad, about 36 miles northwest of Fremont and 80 miles northwest of Omaha. It is in an agricultural region, in which the chief products are wheat and corn. It has a flour mill, creamery, grain elevator, carriage and furniture factories, stock-yards, and coal and lumber yards. There are three banks and two newspapers, besides a high school, graded schools and a school library. Pop. 2,000.

**WEST POINT, N. Y.**, United States military reservation, Orange County, on the west bank of the Hudson River, on the West Shore Railroad, connected by ferry with the New York City, 50 miles north of New York. It is a strategic point for the Hudson River daily traffic. Its site is very picturesque, the east side of the point slopes abruptly to the north on the northern side the slope is more gradual; to the northwest are Crow Nest and Fort Mifflin. The government reservation contains 330 acres, 2,100 of which were acquired by the United States in 1794.

It was occupied as a military post by the British during the Revolution and was later fortified. A part of the fortifications consisted of a strong chain stretched across the Hudson from Constitution Island to prevent British ships from ascending. It was for a time Washington's headquarters; and in 1780 was under the command of Benedict Arnold (q.v.) whose betrayal to the enemy was frustrated by the capture of André (q.v.). West Point was occupied as a military post after the Revolution, and a military school was established there as early as 1794; in 1802 the Military Academy was organized, and West Point designated the site. See MILITARY ACADEMY, WEST POINT, STATES.

**WEST POINT**, town in King William County, Va.; at the junction of the Pamunkey, York and James rivers; at terminus of the Chesapeake and Danville Railroad, 38 miles from Richmond, in a region which was the scene of memorable events in the Civil War. West Point is an important cotton-shipping point. It has extensive docks and wharves, is supplied with water for drinking and cooking by 200 artesian wells, and does a large business in lumbering, canning oysters and exporting fertilizers from phosphatic marl and ash deposits on the Pamunkey. There are cotton compresses, oyster-packing houses, saw-mill, a planing-mill and tinware two female seminaries, a male academy, public and private schools and a large sanitarium, gas and electric-light plant. There is regular steamship communication with Baltimore, New York and Boston. 397.

**WEST POINT, or ELTHAM'S LANDING (q.v.), Engagement at.** When Yorktown was abandoned, 4 May 1781, it was intended by General McClellan that Franklin's division, commanded by Sedgwick's, Porter's and Richardson's, should be moved in transports up York River to a place opposite West Point and, striking across to the main roads, cut off the retreat of the rear of Gen. J. E. Johnston's army as they came below, making their way to New Kent County. But the day before the evacuation of Yorktown, Franklin had received permission to move his men, who had been on the transports for several days, and it was not until the morning of the 26th that he could get them on board again to sail. About 1 p.m. that day he moved at Eltham's Landing, above West Point, his men and sent the transports back to Sedgwick's division. He had no instruction except to wait for orders. The division was encamped on a plain beyond which was a wooded ground, over which ran a road from the landing to Barhamsville, and toward New Kent Court House. Frank-

lin proceeded to occupy the wood. Newton's brigade was put in position on both sides of the road leading to Barhamsville. Parts of Taylor's and Slocum's brigades were on Newton's left; two batteries were in his rear, and two regiments of Taylor's brigade were in reserve. Next morning Dana's brigade of Sedgwick's division continued the left of the Union line back to the river. The presence of Franklin threatened the road through Barhamsville toward New Kent Court House, on which part of the Confederate army was retreating from Yorktown and Williamsburg, and under General Johnston's orders Whiting's and Hampton's brigades had been put in position to protect the road. On the morning of the 7th, soon after Dana's brigade had come up, Whiting was ordered to advance and drive Franklin back to his landing-place. His skirmishers went forward and encountered those of Newton, and closely following came Hood's Texas brigade and Balthis' Virginia battery, supported on the right by two regiments of Wade Hampton's brigade. Newton's skirmishers were driven in and closely followed, then Newton threw forward two regiments, which were driven back, and the entire line was forced out of the wood. On Hood's right Whiting's brigade protected that flank, while on his left S. R. Anderson's Tennessee brigade had come up, and by noon Franklin had been pushed back under cover of the gunboats. The Confederates then attempted to shell the transports in York River, but the range was too great, while the fire from the Union gunboats was effective, and compelled the Confederates to withdraw about 3 p.m., and resume their position near Barhamsville. Franklin's troops resumed their former position. The Union loss was 48 killed, 110 wounded, and 28 missing; the Confederate loss, 8 killed and 40 wounded.

**WEST POINT GRADUATES KILLED IN THE WORLD WAR.** Official information given out by the War Department at Washington, 21 Nov. 1919, disclosed the fact that 33 graduates of the United States Military Academy at West Point were killed in action or died of wounds received in action during the World War. None of these officers was of higher rank than colonel. The list includes three colonels, five lieutenant-colonels, eight majors, nine captains, seven first lieutenants and one second lieutenant. All of the officers were killed in France with the exception of Second Lieut. Albert F. Ward, who was killed at Vladivostok. The officers belonged to 15 graduating classes. The classes of 1917 and 1918 sustained the heaviest losses, six members of the class of 1917 and 10 of the class of 1918 having been killed. The class of 1918 was graduated 30 Aug. 1917, almost a year ahead of time, in order to supply additional officers for the great army which was then being organized. The complete official list of West Point graduates who were killed in action or who died of wounds received in action, with the dates of their deaths, follows:

**CLASSES EARLIER THAN 1915.**

- Class of 1886 — Col. Bertram T. Clayton, Q.M.C., killed in action, 30 May 1918.
- 1892 — Col. William D. Davis, Inf., killed in action, 1 Nov. 1918.
- 1893 — Col. Hamilton A. Smith, Inf., killed in action, 22 July 1918.

- 1906 — Lieut. Col. Robert J. Maxey, Inf., died of wounds, 28 May 1918.  
 1901 — Lieut. Col. Emory J. Pike, Cav., killed in action, 15 Sept. 1918.  
 1903 — Lieut. Col. James A. Shannon, Cav., died of wounds, 8 Oct. 1918.  
 1905 — Lieut. Col. James H. Dickey, Inf., died of wounds, 27 Sept. 1918.  
 1906 — Major Fred A. Cook, Inf., killed in action, 7 Oct. 1918.  
 1908 — Major Arthur E. Bouton, Inf., killed in action, 18 July 1918.  
 1914 — Lieut. Col. Roy M. Smyth, Inf., killed in action, 15 Oct. 1918.

## CLASS OF 1915.

- Major J. H. Reaney, Inf., killed in action, 15 July 1918.  
 Major Harry A. Harvey, P.A., killed in action, 12 Sept. 1918.  
 Major Edwin R. Kimble, C. of E., died of wounds, 9 April 1918.

## CLASS OF 1916.

- Major John H. Willis, C. of E., killed in action, 29 July 1918.  
 Major Alfred K. King, P.A., killed in action, 9 Nov. 1918.  
 Major John A. Street, Inf., killed in action, 4 Oct. 1918.

## CLASS OF 1917.

- Capt. Francis H. Dougherty, Inf., killed in action, 15 Oct. 1918.  
 Capt. Daves Russell, Inf., died of wounds, 13 Oct. 1918.  
 Capt. Stewart W. Hoover, Inf., killed in action, 1 March 1918.  
 Capt. George W. Sackett, Inf., killed in action, 15 Oct. 1918.  
 Capt. Henry H. Chapman, Inf., killed in action, 29 Sept. 1918.  
 Capt. Edward W. Leonard, Inf., killed in action, 14 Oct. 1918.

## CLASS OF 1918.

- Capt. Charles D. Harris, C. of E., killed in action, 20 Oct. 1918.  
 Capt. Thurston E. Wood, P.A., killed in action, 21 July 1918.  
 Capt. Robert E. Symmonds, Cav., died of wounds, 22 Nov. 1918.  
 First Lieut. Edward J. Wolff, Jr., P.A., killed in action, 16 Aug. 1918.  
 First Lieut. Kenneth P. Murray, Inf., died of wounds, 15 July 1918.  
 First Lieut. Louis A. Freeman, Inf., died of wounds, 18 Aug. 1918.  
 First Lieut. Theodore D. Schmidt, Inf., died of wounds, 7 Sept. 1918.  
 First Lieut. Josephus B. Wilson, Inf., killed in action, 15 Oct. 1918.  
 First Lieut. Frank S. Long, Inf., killed in action, 5 Oct. 1918.  
 First Lieut. Earle A. Bilings, Inf., killed in action, 18 July 1918.

## CLASS OF 1919.

- Second Lieut. Albert F. Ward, Inf., killed in action, 22 June 1919.

**WEST POINT MILITARY ACADEMY.**  
 See MILITARY ACADEMY, UNITED STATES.

**WEST RIVER,** China. See SI-KIANG.

**WEST RUTLAND,** Vt., town in Rutland County, on Otter Creek and on the Delaware and Hudson Railroad, about 55 miles southwest of Montpelier, the capital of the State. In 1887 it was set off from Rutland and organized as a separate town. The principal marble quarries, for which this region is famous, are in West Rutland. It has seven churches, graded schools and a library. It is one with Rutland except in government. Pop. about 3,427.

**WEST SAINT PAUL,** Minn., city in Dakota County, on the outskirts of Saint Paul and on the Chicago, Great Western Railroad. It is a residential suburb of Saint Paul. Pop. 2,660.

**WEST SPRINGFIELD,** Mass., town in Hampden County, on the Connecticut River and on the Boston and Albany Railroad, opposite Springfield. It was settled about 1655 and at first was a part of Springfield. In 1774

it was incorporated. It is mainly a residential town, many of the business men of Springfield have their homes here. There are several industrial establishments, chief of which are paper mills, railroad repair shops and machine shops. Many of the people are interested in market gardening. The public library has over 8,000 volumes. Pop. 11,339.

**WEST TAMPA,** Fla., city in Hillsboro County, on the outskirts of Tampa. It is one of the principal cigar manufacturing towns in the United States. Pop. 11,370.

**WEST TERRE HAUTE,** Ind., town in Vigo County, on the Wabash River, on the western outskirts of Terre Haute, and on the Cleveland, Cincinnati, Chicago and Saint Louis Railroad. Its industries include the working of extensive deposits of coal, clay, sand and gravel and there is a paving-brick plant. Pop. 3,084.

**WEST TROY,** N. Y. See WATERVLIET, N. Y.

**WEST UNION,** Iowa, city, county-seat of Fayette County, on the Chicago, Milwaukee and Saint Paul and on the Chicago, Rock Island and Pacific railroads, about 85 miles northwest of Dubuque. It is in an agricultural and stock-raising region and has large creameries, a flour mill and stock-yards. There are three banks and two newspapers. Pop. 1,773.

**WEST VIRGINIA,** prior to its separation from the mother State, known as the Trans-Allegheny Region of Virginia, was admitted to the Union 20 June 1863 as the 35th State. Its area is the 40th among the States, covering 24,170 square miles of which 148 square miles is water surface. It lies between 37° 6' and 40° 38' N. latitude and between 0° 40' and 5° 35' longitude West from Washington. With a very irregular boundary of 1,170 miles, West Virginia is encircled by Pennsylvania, Maryland, Virginia, Kentucky and Ohio. On the northeast, it finds a natural boundary in the south bank of the Potomac. The centre of the Big Sandy serves a like purpose on the southwest. On the west the Ohio forms a navigable boundary for 256 miles — the jurisdiction of the State extending to low-water mark on its western bank. From northeast to southwest the separation from old Virginia, in an irregular and ill-defined line, follows the crest of meandering mountain ridges. The narrow strip in the north between Ohio and Pennsylvania is called "the northern panhandle." A similar extension in the northeast corner is similarly styled "the eastern panhandle"; hence "the Panhandle State." The main part of the State is, in form, a rough oval from northeast to southwest, about 250 miles in length, with an average breadth of 150 miles. Capital, Charleston, in Kanawha County.

**Topography.**— West Virginia is of rolling, uneven surface, and in the east, distinctly mountainous. From the Ohio river in the west to the crest of the Allegheny Mountains on the east, the surface rises with steadily increasing altitude, though irregular surface. This gives rise to three of the four definite physiographic regions of which West Virginia is composed: namely, the Ohio Valley region, the Cumberland Plateau region and the Allegheny Highland region. Crossing the Alleghenies — in the northeastern section of the State we find

the land sloping to the eastward as the Potomac Valley region. The Ohio Valley region extends from the northernmost point of the State southwestward along its western border to the mouth of the Big Sandy. With but a few exceptional points, the general level of this region runs from 500 feet at the mouth of the Big Sandy, to 1,000 feet at Dingess in Mingo County and at Grafton in Taylor County. The total area of this fertile, well-cultivated agricultural section is 8,326 square miles, or 5,327,640 acres. In it lie the largest cities of the State; Huntington, at an elevation of 538 feet, Charleston, 603 feet, Parkersburg, 624 feet, Wheeling, 647 feet, Morgantown, 822 feet and Fairmont, 842 feet, all elevations at railroad level. This region embraces about one-third of the area and more than one-half of the population of the State.

The Cumberland Plateau, with a general elevation from 1,000 to 2,000 feet, parallels the Ohio Valley region, stretching southwestward from the Pennsylvania line to the upper waters of the Big Sandy and the Tug. It crosses the State as a broad belt from 40 to 60 miles in width, rising in swift elevation to meet and merge into the Allegheny Highlands. The rivers of this section, with a fall varying from 12 feet to 25 feet per mile, rush with corresponding velocity and furnish admirable water power. The area of this section is 6,700 square miles or 4,290,000 acres. Within it are found many of the smaller cities and prosperous towns of the State,—Clarksburg at an elevation of 1,008 feet; Weston, 1,017 feet; Buckhannon, 1,401 feet; Welch, 1,297 feet; Hinton, 1,378 feet, and Elkins, 1,920 feet. This section nurtures and maintains about one-fourth of the State's population.

The Allegheny Highlands takes its name from the predominating mountain range. The general topography is marked by the long, regular, symmetrically-parallel folds of the Allegheny mountain system. Mountain rolls beyond mountain till the lofty Allegheny crest rises as a barrier wall between the two Virginias. Various parallel and outlying extensions serve to broaden this mountain section which covers, at an altitude ranging from 2,000 to 4,000 feet, nine counties of the State and reaches partly across seven more. The highest peak in the State is Spruce Knob, in Pendleton County, 4,860 feet. Other points of high elevation in this section are High Knob, 4,710 feet and Sharp Knob, 4,545 feet, with more than 20 other peaks exceeding 4,000 feet. Richwood, Nicholas County, 2,189 feet; Coal-dale, McDowell County, 2,336 feet; Terra Alta, Preston County, 2,549 feet; Horton, Randolph County, 2,729 feet; Fairfax, Grant County, 3,060 feet, are thriving coal and lumber towns of high altitude.

The Potomac region consists of the five counties lying east of the Allegheny Mountains and gradually sloping to the lowest point in the State, 286 feet, at Harper's Ferry. The area of this section is 1,780 square miles, or 1,139,200 acres, and the population closely approximates 100,000 people. Broad bottom lands border the rivers and creeks of this section. The lower Shenandoah Valley extends through Berkeley and Jefferson counties, rich alluvial soil and highly cultivated. The agricultural

life of the State reaches its highest development in this section.

**River System.**—The drainage of West Virginia is accomplished by two river systems each entirely distinct from the other. From the culminating apex of the Alleghenies at the junction of Pendleton, Pocahontas and Randolph counties, the eastern drainage is through the Potomac into Chesapeake Bay and the Atlantic Ocean. The western drainage, by far the greater, crosses the State in six river basins, tributary to and forming part of the Ohio system and finally, through the Mississippi and the Gulf of Mexico, likewise mingles with the waters of the Atlantic. The drainage areas are as follows: on the east, the Potomac and its tributaries 3,500 square miles; on the west, the Monongahela and its tributaries 4,300 square miles; the Little Kanawha and its tributaries 2,200 square miles; the Great Kanawha and its tributaries 8,800 square miles; the Guyandotte and its tributaries 1,800 square miles; the Twelve Pole and its tributaries 500 square miles; the Big Sandy and Tug and their tributaries 2,300 square miles. The Ohio is navigable for its entire length up to Pittsburgh. From thence the Monongahela is dammed for slack water navigation as high up as Fairmont. The Great Kanawha is navigable for 90 miles, as far up as Montgomery. West Virginia enjoys thorough irrigation and complete drainage. Not a single square mile is without proper irrigation yet not a single square mile of stagnant water is to be found.

**Climate and Rainfall.**—West Virginia has a continental climate with the usual variations arising from an extent covering  $3\frac{1}{4}^{\circ}$  of latitude and 4,500 feet of altitude. The mean annual temperature at Wheeling in the northern part is  $51.64^{\circ}$ ; at Charleston in the southern part,  $54.27^{\circ}$ ; of the State,  $52.30^{\circ}$ . Between the last damaging frost in spring, 10–20 April, and the first killing frost of autumn, 10–20 October, there is, every season, ample time to mature fully crops of every variety. The average annual precipitation, including melted snow, is 45 inches. Southwest winds prevail in West Virginia, though somewhat broken up and deflected by the rugged contour.

**Geology, Mineral Resources and Mining.**—That portion of the earth's crust which is in evidence in the northern and eastern part is made up chiefly of limestone and sandstone. Three well-known and easily-recognized limestones are found here,—the Shenandoah or Trenton; the Lewiston or Helderberg and the Mountain or Greenbrier limestone. Three sandstones exist in like profusion,—the indestructible Medina, the more friable Monterey or Oriskany and the Hamilton shale. Preceding the carboniferous measure is the Great Conglomerate or Millstone Grit, extending across the centre, while the remaining western two-thirds of the State is formed principally of coal measures made up of alternating layers of shales, sandstones, fire clays and coal seams. Some peat is found in the cold and densely-shaded uplands of the Allegheny Highlands.

West Virginia has no deposits of the more valuable metallic ores, though rich in the common minerals. Her most important mineral is coal in the production of which she ranks

second only to Pennsylvania. The Appalachian coal field, like an Indian canoe in shape, with one prow in northern Pennsylvania and the other in western Alabama, extends from the north to the southwest throughout West Virginia. Here it reaches its greatest width, about 100 miles and shows its richest deposits of bituminous coal of varying kinds and qualities. In length 150 miles with an average breadth of 65 miles, the approximate area of the State's coal bed is 9,500 square miles or 6,080,000 acres. Within this area are to be found 85 different seams of coal. Of the 55 counties of the State, 49 are underlain with coal. More numerous seams of greater thickness, aided by favorable topographical conditions, render it possible, at the same rates of labor, to mine coal in West Virginia at less expense and with greater economy than in any other State, without exception. In 1917, 1,000 mines in operation furnished nearly 16.5 per cent of all the coal produced in the United States. The production fields, formerly five in number, have of late years been reclassified into 11 distinct fields. For the fiscal year ending 30 June 1914—the Department of Mines reports the following production in short tons: Pocahontas, 18,934,335; Fairmont, 13,115,416; New River, 11,384,111; Kanawha, 10,736,285; Logan, 6,209,748; Preston-Barbour, 4,797,676; Mingo, 2,873,503; Elk Garden, 2,316,275; Panhandle, 2,213,799; Putnam, 621,514; Mason, 138,466; all other mines 336,000, making the total production for 1914, 73,677,058 short tons. Subsequent reports show production for 1915, 74,184,169; 1916, 79,612,298; 1917, 89,353,450 short tons. The total amount of coal stored in the hills of West Virginia is estimated to exceed 160,000,000 short tons, which, at the present rate of production, would not be exhausted in 1,800 years; in fact, the entire production of coal credited to this State to 30 June 1917 exceeds but 1,000,000,000 short tons. So far the coal deposits of West Virginia have only been scratched. Owing to the moderate development of manufactures and the large consumption of natural gas—only 8 per cent of the coal produced is used within the State. Prior to 1910, West Virginia showed annually a steadily-increasing production of coke. High tide was reached that year with 4,217,380 tons valued at \$7,525,922. The Solvay process of securing the by-products and other methods of conservation have taken the place of the coke oven. There has been a steady diminution in coke production since 1910, the production in 1916 being 1,957,632 tons. Iron ore exists in West Virginia to the extent of 300,000,000 tons or more. The only production to date is at Orebank on the Potomac above Harper's Ferry and that is less than 20,000 tons annually. The chief deposits are in the wild mountain regions, remote from transportation facilities and are at present inaccessible for commercial mining.

No beds of rock salt have yet been reached in the deep borings made, but brines of great salinity have been secured from wells of varying depth throughout the State. These brines of great strength and abundance are readily accessible for the increased production of salt and its by-products. At present, the production is confined to the Great Kanawha Valley just above Charleston and along the Ohio River in

Mason County. In the latter region, ex across the river into Meigs County, is the greatest bromine manufacturing in this country producing 70 per cent of the output in the United States.

Inexhaustible deposits of almost solid stone unmixed with shales stretch for miles in length and several in breadth to the east and northeast. This lies in two belts. The one follows the Potomac along both the north and south branches other west of the Allegheny crest and to it, extends from the Pennsylvania-Preston, to the Virginia line in Mercer. This latter is of Mountain or Greenbrier former of Shenandoah limestone. Greenbrier, along the Baltimore and Martinsburg east, produce a large quantity of lime and limestone of high grade. West Virginia takes second rank in glass sand production, with immense deposits of the finest quality. The main quantities are in Morgan near Berkeley Springs. Great quantities of lower grade are mined also in Preston and Monongalia counties.

West Virginia abounds in mineral springs with old Virginia that celebrate known as the "Spring Region." In Morgan County, also in "The Warm Springs" and "Bath Springs" have been known to civilization since 1744, famous for its unceasing supply of water at the rate of 2,000 gallons per minute, at a normal temperature of 70°. It is now controlled by the State to whom it was given by Lord Fairfax. Of the remaining 100,000 more of health resorts the most famous are Greenbrier White Sulphur Springs, in Mingo County, "the Saratoga of the South." The springs of the State present a variety of chemical composition and therapeutic value. They comprise sulphur, chalybeate, iron, or carbonated, saline, aluminated, or thermal waters.

**Oil and Gas.**—The latest United States reports show a diminution in production of oil in West Virginia during the five years 1912-16, with an increase of value. 12,128,962 barrels were marketed at an average price per barrel of \$1.643, making a value of \$19,927,721. In 1916 8,731,184 barrels were produced, selling at an average price per barrel of \$2.51, a value of \$21,914,080. Lack of discovery of new pools and the small capacity of new wells sunk has failed to offset the decline in production in the older districts.

Since 1906 West Virginia has ranked among all the States in the production of natural gas. The increase in production has been rapid of late years. In 1915 it was 599,000 cubic feet, in 1916, 299,318,907.0 cubic feet, and in 1917, 305,264,926,000 cubic feet, a value of \$50,000,000. This is probably the highest tide in gas production, at least for the decade. War conditions, less drilling and a natural decline in productive capacity have diminished the supply. The year ending 30 June 1918, shows 289,123,513,000 cubic feet. Virginia contains 30 per cent of all the gas land acreage, and 21 per cent of the productive gas wells in the United States. Per cent of all the natural gas produced in the United States is furnished by West

The State consumes itself 13.5 per cent of all the natural gas consumed in the United States, 45 per cent of the population depending on gas for lighting, heating and cooking. It is conveyed by pipe lines to the leading cities in the State, and to Cleveland, Ohio, Cincinnati, Ohio, Pittsburgh, Pa., and Baltimore, Md. The approximate investment in gas plants, service connections and gas-using appliances is \$137,000,000. In importance the gas business in the State is second only to that of coal.

**Agriculture, Horticulture and Stock Raising.**—The total value of farm property in West Virginia in 1910 was \$314,738,540, of which amount land was represented by \$207,075,759; buildings by \$57,315,195; implements and machinery by \$7,011,513; and livestock by \$43,336,073. This total was an increase in 10 years of \$110,831,191. The additional increase of the past eight years will place this value (1918) at \$400,000,000. The value of the farm products included cereals, \$15,997,700; hay and forage, \$7,492,747; potatoes, \$2,278,638; sweet potatoes, \$170,086; tobacco \$1,923,180; dairy products, \$5,000,138; poultry and eggs, \$9,215,289; wool, \$839,555; honey and wax, \$231,630; and domestic animals sold and slaughtered, \$18,456,122. The total land area of the State is 15,374,080 acres. Of this 10,926,442 acres are held in farms, of which 5,521,757 acres are improved. From the northeast corner of the State extending south and southwest to the Big Sandy River the country is mountainous with narrow valleys. There are no transportation soils, all being from disintegration of limestone, sandstone, or mixtures of shales and clays. The soil is generally fertile and does not wash into gullies, and the land is productive to the tops of the mountains. Clay soil is found in some of the higher portions, alluvial soil in the upland valleys, and unproductive sandy soil in the northeast. In the extreme northeastern counties the soil is of rich limestone. West of the mountains the broad flat hills furnish grazing for cattle, while the valleys produce good crops. The surface near the Ohio River is gently rolling and the soil—clay and sand loams—is rich. Farms are now decreasing in size and are more intensively cultivated. The average size is now 103.7 acres with an average value of \$3,000. On most of the farms the principal source of income is from stock raising; hay and grain come next in value; in the eastern panhandle, apples grown for commercial use prove a profitable source of income. The crops for 1918 were (United States Bureau of Crop Estimates) corn, 24,911,000 bushels; hay, 1,000,000 tons; wheat, 4,837,000 bushels; buckwheat, 917,000 bushels; potatoes, 5,568,000 bushels; sweet potatoes, 212,000 bushels; tobacco, 10,200,000 pounds; apples, 1,145,000 barrels, an increase of 443,000 barrels over 1917. The leading domestic animals with their values, in 1916, were—horses, \$21,340,000; mules, \$1,800,000; milch cows, \$14,460,000; other cattle, \$14,480,000; sheep, \$4,178,000; swine, \$3,402,000. The largest corn growing counties are Wayne, Kanawha, Jackson and Mason; Jefferson, Berkeley and Mason lead in the production of wheat; Hampshire, Hardy and Morgan in rye; and Preston, in oats and buckwheat. West Virginia offers unusual orchard possibilities and,

with improved transportation facilities, there is a corresponding extension and development of fruit industries. In 1910 there were 7,000,000 fruit trees of bearing age and 5,000,000 under bearing age, a total of 12,000,000. A careful estimate this year places this total in excess of 16,000,000. Some of the largest and most profitable apple and peach orchards in the whole country are in West Virginia. The State to-day produces more apples than the entire section of the United States west of the Mississippi. The average output of Berkeley County (500,000 barrels) exceeds the entire crop of either Oregon or Washington, the apple growing States of the Pacific section. Small fruits (berries) are raised in Brooke, Harrison, Ohio and Wood counties; tobacco in Lincoln, Wayne, Putnam and Cabell counties. The average expenditure on each farm for labor is \$22, which shows that the West Virginia farmer does most of his own work. The United States Agricultural Experiment Station is located at Morgantown and is conducted by the State University.

**Timber and Lumbering.**—There are 15,000 square miles of timber lands in the State, about 74 per cent of the total area. The largest hardwood mills in the world are in Pocahontas, McDowell and Randolph counties. High-water mark in production in West Virginia seems to have been reached in 1909, since which time there has been a slight decrease. The cut of the saw mills for this and four succeeding years was 1909, 1,472,942,000; 1910, 1,428,789,000; 1911, 1,387,786,000; 1912, 1,318,732,000; 1913, 1,249,559,000 feet. The saw mills, during this period, probably reached their maximum; 1,524 in operation, of which 83 were band-saw mills. There are large forests of white pine in the upland regions which scarcely have been touched by the lumberman. The densest forests are in the eastern and southern counties. The principal trees of value found in the State are oak, both red and white, and chestnut, hickory, locust, maple, poplar, birch, hemlock, white pine and spruce. With the multiplication of short railroads and the installation of larger mills, the virgin forests are being reduced rapidly and yet lumbering will continue for years a leading industry of the State.

**Manufactures.**—In 1914 there were in West Virginia 2,749 manufacturing establishments, with capital invested \$175,595,011 and production valued at \$193,511,782. Seventy-nine thousand three hundred and fifty-three persons were employed earning \$51,377,760. West Virginia, with its vast deposits of coal, great oil pools, immeasurable gas supply and innumerable opportunities for hydro-electric power, possesses inestimable advantages for turning raw material into finished products. Present recognition of this fact is giving promise of rapid growth in manufacturing lines. The added advantage of water transportation along the Ohio has had its effect; the 12-river counties furnish over 60 per cent of the manufactures. The leading manufacturing counties, each producing over a million dollars' worth, are Ohio, Marshall, Wood, Kanawha, Cabell, Tucker, McDowell, Berkeley, Fayette, Randolph, Marion, Morgan, Mineral, Jefferson and Grant. By the same report (United States Census of Manu-

factures 1914) the cities of the State (pop. over 10,000) rank in manufacturing as follows:

Wheeling, 201 establishments, with capital \$26,857,896, and giving employment to 9,098.  
 Huntington, 102 establishments, with capital \$7,843,648, and employment to 5,079.  
 Parkersburg, 83 establishments, with capital \$5,741,036, and employment to 2,179.  
 Fairmont, 50 establishments, with capital \$5,276,426, and employment to 2,048.  
 Charleston, 89 establishments, with capital \$3,226,595, and employment to 1,333.  
 Martinsburg, 37 establishments, with capital \$2,629,707, and employment to 1,709.  
 Moundsville, 27 establishments, with capital \$2,530,369, and employment to 1,692.  
 Morgantown, 49 establishments, with capital \$2,306,383, and employment to 1,600.  
 Bluffield, 24 establishments, with capital \$1,129,602, and employment to 1,337.  
 Clarksburg, 43 establishments, with capital \$948,306 and employment to 422.

Lumber and timber products still continue the leading industry in the State, giving employment to 17,417 wage-earners, with production valued at \$28,994,240. Iron and steel products easily take second place, with 6,823 employed, and production valued at \$28,795,938. Glass-making sands and natural gas have given West Virginia fourth place among glass-producing States. Sixty-three establishments employ 8,889 wage-earners and turn out products valued at \$14,631,171. Tanneries, in number 18, employing 1,072 men, produce leather to the value of \$11,014,540. Railroad shops, in construction and repair of cars, employ 8,437 men and turn out product worth \$10,990,193. Other important industries are flour and grist mills with a production of \$7,052,814; and brick, tile, pottery and other clay products amounting annually to \$6,798,118. From 1899 to 1904 the value of manufactures increased 47.8 per cent; from 1904 to 1909, 63.5 per cent; and from 1909 to 1914, 19.5 per cent. In 1918, the United States government completed two great war industries—a projectile plant at Charleston and a high-explosives plant at Nitro, 16 miles down the Kanawha—-at an expenditure of more than \$60,000,000. The future status of these immense plants, just beginning production, is left uncertain by the termination of the war.

**Railroads.**—The railway mileage in West Virginia is approximately 4,000 miles. Three trunk-lines cross the State: The Baltimore and Ohio, in the northern part, from Harper's Ferry to Wheeling with "the Southwestern" branching off at Grafton and crossing the Ohio at Parkersburg, and the Ohio River branch following the river from Wheeling to Kenova. The Baltimore and Ohio with many short branches fairly well covers the western part of the State. The Chesapeake and Ohio, in the southern part, crossing the mountains into the State at White Sulphur Springs, follows the Greenbrier and Kanawha valleys until it strikes the Ohio River at Kenova and crosses the Big Sandy into Kentucky. It has 22 tributary short lines in this State. The Norfolk and Western crosses the Ohio into West Virginia at Kenova and with four branches traverses the Big Sandy valley and southwestern part, leaving the State at Wills, in Mercer County. Other railroads are: The Western Maryland—from Baltimore to Belington—crossing the Potomac River just above Piedmont and running south 101 miles into the State with eight short branches; the Virginian, from Norfolk to the

West Virginia coal fields—entering the State at Rock, in Mercer County—connecting the Norfolk and Western at Matoaka miles further on, with the Chesapeake at Deepwater; the Kanawha and M entering the State at Point Pleasant and following up the Kanawha River to Bridge; the Coal and Coke, 175 miles from Charleston to Elkins. Numerous other lines of less importance traverse the State and feed into these larger lines. The great production of coal, coke and lumber is crowded with present facilities for transportation and doubtless lead to further railroad construction in the near future.

**Banks and Banking.**—By complying with certain legal requirements, charters for banks may be obtained from the secretary of State. There must be a capital not less than \$500,000, and not more than \$500,000. Ten per cent of the capital must be paid in before the granting of the charter, and 40 per cent before the bank can open for business. The State commissioner of banking has authority over the State banks which does not, however, extend to the national banks. The condition of the banks, 30 June 1917, was as follows:

	National	State
Number	115	112
Capital	\$10,087,000	\$13,731,000
Surplus	6,731,000	8,881,000
Loans	68,515,000	89,112,000
Deposits	94,582,000	112,000,000

**Finances.**—West Virginia is in a very poor financial condition. It would have been in a worse condition whatever were it not for the recent decision of the United States Supreme Court that the State must assume its share of the ante-bellum debt of Virginia. With accrued interest the State is debited with \$12,393,928. The State has at present in bonds and other securities \$2,970,400, of which \$936,400 stands in credit of the school fund and \$2,034,000 in workmen's compensation fund. The funds are deposited with various banks as State depositories and draw 3 per cent interest. The receipts for the fiscal year ending 30 June 1917 were \$5,071,911.37 and the disbursements \$4,034,835.06. The State debt in 1918 is seven cents on \$100 and the valuation, including public service corporations, is \$1,366,139,828.

**Education.**—The educational system of West Virginia is rapidly developing in scope and efficiency. In 1916 the total amount expended for the State educational system was \$772,280, of which the expenditure for common schools was \$6,438,007, an increase of more than 57 per cent over the expenditure of \$4,094,092 in 1910. The enumerated population is 6 to 21—entitled to public education, privileges, was 419,890. Of these 313,885 were enrolled, making a per capita expenditure of \$20.51. Ten thousand three hundred and twenty-four teachers were employed, 9,886 of whom were white and 438 colored in 6,874 buildings. The State constitution provides for separate schools for the negroes. The average term of school is six and three-fourths months of 20 weeks. The average salary for the term \$332.77, and the total value of public school property was \$91,531 in 1916 as against \$9,331,694 in 1910. The number of high schools was 164 in

WEST VIRGINIA

2 View of Cheat River in the Mountains of West Virginia

were county, 115 district and 46 town and high schools. The total high school enrollment was 13,961. Most of the rural schools are being consolidated for greater efficiency making rapid headway. Agriculture is being studied in all the schools, while manual training and domestic science are being widely introduced in many of them. Of the States, Maryland and Delaware are the only ones having a lower percentage of efficiency. A still greater degree of efficiency in school administration is anticipated from a pending revision of the school law—a commission appointed for that purpose is expected to report to the next legislature. For secondary and higher education the State supports two preparatory schools for the city, at Montgomery and at Keyser, and normal schools, at Athens, Huntington, Liberty, Glenville, Fairmont and Shep-  
 own. Two similar schools for negroes are located at Bluefield, Mercer County, and titute, Kanawha County. Storer College (for negroes) at Harper's Ferry is a private institution, aided by an annual State appropriation. The capstone of the State educational system is the West Virginia University of Morgantown. Other institutions of collegiate grade are Bethany College (Christian) at Bethany, West Virginia Wesleyan (Methodist) at Buckhannon; Morris Harvey College (Methodist Episcopal South) at Barboursville; and Elkins (Presbyterian) at Elkins and Elkins College (non-sectarian) at Salem. These are all coeducational. Prominent secondary schools are Linsly Institute (non-sectarian) and St. Joseph's (Roman Catholic) at Wheeling, Broadus Institute (Baptist) at Philippi, and Fairmont Seminary (Presbyterian). The Roman Catholic Church has large parochial schools at Charleston, Huntington, Parkersburg, Benwood, Wheeling, Clarksburg, Grafton and Martinsburg. Prosperous business concerns are located at Wheeling, Clarksburg, Parkersburg, Huntington and Charleston.

**Libraries.**—In 1916 there were 4,899 public libraries, totaling 428,896 books, valued \$2,275,900. Good libraries are maintained in normal schools and various sectarian institutions. The largest general libraries in the State are at Wheeling, Huntington, Parkersburg and West Virginia University at Morgantown. At Charleston the State Law Library has 23,000 volumes and the library of the Department of Archives and History over

The corrective institutions are the Reform School for Boys at Pruntytown; the Industrial Home for Girls at Salem; the State Penitentiary at Moundsville. This latter institution is more than self-supporting.

**Population.**—The State's population at each Federal census has been as follows: (1870), 442,014; (1880), 618,457; (1890), 762,794; (1900), 958,800; (1910), 1,221,119. Recent decades each show an increase of more than 25 per cent. In 1910 the State ranked 28th in population. Estimates of the Bureau of Census give, 1 July 1917, 1,412,502 and 1 July 1918, 1,439,165. Of these 79,000 are negroes. The same source gives municipal estimates 1 July 1917 as follows: Bluefield, 16,123; Charleston, 31,060; Clarksburg, 12,960; Fairmont, 16,111; Huntington, 47,680; Martinsburg, 12,984; Morgantown, 14,444; Moundsville, 11,513; Parkersburg, 21,059; Wheeling, 43,657.

The census of 1910, in detail, gives urban population, 228,462; rural population, 992,877; male, 644,044; female, 577,075; native-born, 1,163,901, of whom white, 1,156,817, negroes, 64,173; foreign-born, 57,218, of which 24,911 are Germans, 21,183 Italians, 18,446 Austro-Hungarians, 13,633 English and Scotch, 13,138 Irish. The foreign population lies chiefly in Marion, Marshall, Ohio, Tucker and Wood counties—in the mining districts and in the cities. The counties of greatest negro population are Berkeley, Cabell, Fayette, Greenbrier, Harrison, Jefferson, Kanawha and McDowell. In no county do the negroes total 50 per cent of the population. The cities having the largest proportion of blacks (3,000 to 5,000) are Charleston, Huntington and Bluefield. The principal immigration into West Virginia, excluding foreigners, has been (by census of 1900) from Virginia, 61,508; from Ohio, 40,301; from Pennsylvania, 28,927. The white voters are 247,970, of whom 23,577, 11 per cent, are illiterate. The black voters are 14,786, of whom 5,583, 38 per cent, are illiterate. Seventy-four thousand eight hundred and sixty-six illiterates are in the State, 8.3 per cent of the population above 10 years of age. The school-age enumeration (6 to 21) is 396,818, of whom 259,971 attend school. More recent figures (Free Schools Report, 1918) show an enumeration of 437,620 and a school enrollment of 313,873.

**Churches.**—The churches in West Virginia in order of membership are Methodist Episcopal; Baptist (North); Methodist Episcopal (South); Catholic; United Brethren; Methodist Protestant; Presbyterian; Disciples; Colored Baptists, Regular; Episcopal; Free Will Baptists; Lutheran, United Synod, South; Lutheran, General Synod; Baptist (South). Eighty-six per cent of the church membership is Protestant. There are 3,486 Sunday schools in the State, with 27,577 officers and teachers and 212,577 scholars.

**Government.**—The governor, auditor, treasurer, secretary of state, attorney-general, superintendent of free schools and commissioner of agriculture constitute the executive corps of West Virginia, and form the board of public works. This board looks after the interest of the State in all internal improvements; fixes the direct State tax, and assesses for taxation all railroads, pipelines and public utility property. All the officials above named except the

**Asylums and Reformatory Institutions.**—The State maintains the following charitable institutions: Hospitals for the insane at West Spencer; home for incurables at Huntington; miners' hospitals at Fairmont, Meigs and Welch; a school for the deaf and blind at Romney; a tuberculosis sanitarium at Alta; a tuberculosis sanitarium (for whites) at Denmar, Pocahontas County; and a home for orphans at Huntington; The Ring Arms Hospital at Hansford and the G. W. Memorial near Moundsville are supported by the Episcopal Church; the West Virginia Humane Society, appointed by the governor, is a member from each congressional district in the care of the aged and infirm, destitute children and animals.

attorney-general are obliged to reside at the capitol. All are elected every four years. Each of the above officials report in writing to the governor 10 days before the meeting of the legislature. The governor must have resided in the State five years and must be at least 30 years of age. In case of a vacancy in the governorship within the first three years after election a new election is held. If the remainder of the term is less than one year the president of the senate acts as governor, and after him the speaker of the house is eligible. The salaries paid are as follows: Governor, \$5,000; secretary of state, \$4,000; superintendent of free schools, \$4,000; treasurer, \$3,500; auditor, \$4,500; the attorney-general, \$4,000; and the commissioner of agriculture, \$4,000. The auditor is not only comptroller of the currency but is also register of the land office and commissioner of insurance. Other State officials are the tax commissioner, commissioner of banking, commissioner of labor, compensation commissioner, road commissioners (two), chief of department of mines, health commissioner, game and fish warden, State geologist, State historian and archivist, State librarian, fire marshal and adjutant-general.

The public service commission, three members, is a court of the people in all complaints against public utilities. The board of control, three members, has the financial management of all institutions, charitable and educational, receiving State appropriations. The board of education, six members, three from each dominant party, together with the State superintendent as chairman ex-officio, has control of the educational affairs of the university, the normal schools and other State educational institutions.

The election for State officials is held at the time of the Presidential election and the new officials take office 4 March of the next year. The legislature meets biennially in January of the odd-numbered years and may remain in session not more than 45 days. Half of the senators are elected every two years, and all of the members of the house of delegates. There are 30 senators, two from each of 15 senatorial districts, and, by present apportionment, 94 delegates. A senator must be at least 25 years of age, but only voting qualifications are required of a delegate. The pay is \$4 per diem and mileage. A simple majority suffices to override the governor's veto; after five days a bill may become a law without his approval. The legislature is prohibited from anything except general legislation. The State is divided into six congressional districts. The judiciary is composed of (1) the Supreme Court of Appeals; (2) Circuit Courts; (3) nine courts of limited jurisdiction; (4) the courts of county commissioners; (5) justices of the peace; (6) City Courts. The Supreme Court is composed of five judges elected for 12 years, and holds its sessions at Charleston. The judges are paid \$5,500 and mileage. There are 23 circuit judges for 23 Circuit Courts; they are paid \$3,300 and mileage. A Circuit Court is held four times a year in each county. The rapid development of some parts of the State rendered more courts necessary, so the legislature created nine courts of limited jurisdiction with appeal to the Circuit Courts. Each county is divided into from three to 10 magisterial dis-

tricts, and each district elects one justice of the peace, or two if the population is greater than 1,200. These justices have the usual powers of American justices of the peace, and jurisdiction over civil suits involving \$300 or less. The County Court is not a common-law court and not a court of record, but rather an administrative board for county affairs. There are no chancery courts, but the courts of record have equity jurisdiction; in equity cases the trial court may appoint four commissioners in chancery who decide such questions as the court refers to them and upon their decisions and reports the judge bases his decrees. Notaries public and commissioners are appointed by the governor without limit as to number. The unit of local government is the county under the usual elective county officers; county commissioners, sheriff, clerk, tax assessor, surveyor, etc. The township system was adopted in 1863, but did not work satisfactorily, and in 1872 was abolished and the old county system revived.

**History and Politics.**—Governor Berkeley of Virginia, in 1670, commissioned Maj.-Gen. Abram Wood "for the finding out the ebbing and flowing of the water on the other side of the mountains." The next year Wood sent out Capt. Thomas Batts and four men. They left Appomattox, now Petersburg, Va., 1 Sept. 1761, crossed the Blue Ridge 7 September, the Alleghenies, 10-13 September, and reached the Great Kanawha at "the Falls," 16 September. Governor Spotswood, in 1716, led a party of 30 cavaliers, crossing the mountains at what is now Pendleton County. In commemoration of this expedition and to encourage westward emigration he founded the "Knights of the Golden Horseshoe," with the motto "Sic jurat transcendere montes." In 1725, John Van Meter explored the valley of the South Branch. In 1727, Morgan ap Morgan built the first cabin in what is now Berkeley County. After 1735, the South Branch Valley began to fill up with the overflow from the Shenandoah Valley and from Pennsylvania and Maryland. The settlers were of several nationalities—and the composition of the people of West Virginia has always been different from that of the country east of the mountains. Some of the land in West Virginia was embraced in the "Northern Neck" grant to Lord Fairfax, and his surveyors, in 1746, planted the Fairfax stone at the head of the North Branch of the Potomac to mark the western limits of the grant. The first permanent settlement west of the Alleghenies was made, in 1764, by John and Samuel Pringle, at Turkey Run, now in Upshur County. In 1768, after the expulsions of the French who claimed the territory drained by the Ohio, the Six Nations sold the land to the English, though several other Indian tribes claimed the country. But within historic times no Indians have ever occupied any part of West Virginia. The attempts of the whites to take possession of these Indian lands led to bloody conflicts that lasted until after the Revolution. The West Virginians heartily supported the Revolution and sent troops to help New England and the Middle Colonies. The history of western Virginia before 1861 is a history of controversy with eastern Virginia. Socially, politically and economically the two sections of the State were unlike from the first. Western

was democratic, eastern Virginia was tied in institutions. The idea of separation was older than the Union; the Congress had been petitioned to set up a state of the Alleghenies; the people of the west were always ready for independence. The counties complained that they were governed to the benefit of the eastern counties. Tennessee and Kentucky, western Virginia waited half a century for separate existence. The crisis came during the movement in 1861. The Virginia Congress passed the ordinance of secession, the counties from the western counties opposing, and it was put to the people. From November to May 1861 meetings were held in the counties which made it clear that they would not go with the South. An irregular convention of 26 counties met in Wheeling in 1861 and came near breaking away by a vote on the ordinance of secession. The western counties voted 40,000 against and for secession. The second Wheeling Congress composed of the newly-elected members of the legislature and irregularly-elected members from the counties west of the mountain on June 11, declared the ordinance of secession void, vacated the offices of the State of Virginia and formed a "reorganized" government of Virginia, with Frances H. Pierpont as governor. The legislature calling itself the legislature, elected senators for Virgil S. Carlile and Waitman T. Willey, and received at Washington. The Congress made a provision for organizing a new government calling a third convention at Wheeling on 6 November, in which 41 counties were tied. A constitution for the new State was drafted and ratified by the people in April 1862; it was at first proposed to call the new state Kanawha, but the name West Virginia was finally adopted. The "reorganized" government of Virginia gave its consent to the new State, and on 31 Dec. 1862 the new State consented to admit West Virginia to the Union, as soon as it should provide for the abolition of slavery. On 20 April 1862 President Lincoln issued his proclamation, in accordance therewith, West Virginia as the 35th State of the Union, 20 June

1862. The long desired separation was effected, not during the Civil War as a cause, but rather as an act of independence. During the war no important military operations were carried on in West Virginia. The Confederates early lost control of the State, but there were skirmishes and raids at the end of the war. However, as with the other Southern States, West Virginia suffered little. From the State 10,000 soldiers entered the Union army and 10,000 went into the Confederate States. Laws were passed by the legislature during the war the property of the Confederates, and the war all Confederates and Confederate sympathizers were disfranchised from holding office. In 1860 it was reported that 29,316 persons—nearly the voting population—were disfranchised. The election of 1870 overthrew the Republican party and gave the control of the State affairs to the Democrats. The next year the constitution was framed, the question of franchise, and this was

endorsed by the people of the State August 1872. The Democrats retained control of the State until 1896 when the Republicans carried the elections. This change in political complexion was due to the great industrial development of the State which attracted a heavy immigration from the States north and west. West Virginia was the first State to begin the undoing of reconstruction; and the first to break from the ranks of the "Solid South." The first break in Republican control of the State took place in 1916 when Cornwell (Dem.) was elected governor over Robinson (Rep.) by a 2,755 majority. At the same election Hughes (Rep.) for President carried the State by 2,721 over Wilson (Dem.). In 1912, the State went "dry" by a majority of 92,342 for the prohibitory amendment. In 1918 a "Budget Amendment," governing the legislature in the matter of appropriations, was added to the constitution by the vote of the people.

WILSON M. FOULK,

*Late State Historian and Archivist.*

**WEST VIRGINIA CAMPAIGN OF 1861.** At the outbreak of the Rebellion, West Virginia had few slaves, no sympathy with the secession movement and adhered to the Union.

\* As president of the senate, filled the unexpired term of Governor Boreman, who had been elected to the United States Senate.

† Title over the governorship contested by Nathan Goff—contest lasting eleven months.

Her citizens denounced the action of the State convention in adopting an ordinance of secession and at town and county meetings passed resolutions looking to a separation of the western counties from the rest and the organization of a new State. On 13 May 1861 a delegate convention was held at Wheeling, 26 counties being represented by nearly 400 leading Union men, and an interchange of views resulted in a decision to secede from the State should the ordinance of secession be ratified by the vote of the people to be given on the 23d of May, and a provisional convention was called to meet on 11 June following. The vote cast on 23 May was large and showed a majority against secession in the west. Out of a vote of about 44,000 in 50 counties 40,000 were against the ordinance of secession.

Meanwhile Governor Letcher had called out the militia of West Virginia and ordered officers to protect the Baltimore and Ohio Railroad and guard the frontier of the State against invasion by Ohio and Pennsylvania. The principal officer assigned to this duty was Col. Geo. A. Porterfield, who 4 May was ordered by Gen. R. E. Lee to Grafton to call out the militia and enroll volunteers to protect the railroad and encourage secession sentiment. Five thousand men were thought ample for the purpose, but Porterfield could not raise a 10th of that number and troops had to be sent from the eastern part of the State. General Lee had informed Porterfield that it was not intended to interfere with the peaceful use of the railroad, but Governor Letcher, incensed at the overwhelming Union sentiment and the apathy of the citizens in volunteering, and moved also by the collection of Ohio troops on the border, ordered Porterfield to make a descent on Wheeling, seize and carry away the arms sent there by the national government and arm his men with them, and specially commanded that should troops of Ohio or Pennsylvania endeavor to pass over the railroad, to destroy it and the bridges. To seize Wheeling was impossible with the few men at his disposal, but, convinced that the Ohio troops were on the eve of a movement eastward, Porterfield burned the bridges of the railroad between Farmington and Mannington. This action was immediately followed by the occupation of the railroad and contiguous country by loyal West Virginia, Ohio and Indiana troops, under command of General McClellan, who had been assigned to the command of a military department embracing Ohio, Indiana, Illinois and West Virginia. Upon the advance of these troops from Wheeling and Parkersburg on the 27th, Porterfield abandoned Grafton on the 28th and fell back to Philippi, from which place he was driven on 3 June to Beverly. (See PHILIPPI, ENGAGEMENT AT). General Garnett was sent to relieve Porterfield and took position at Rich Mountain and Laurel Hill. Col. John Pegram's detachment at Rich Mountain was attacked and defeated by McClellan 11 July, many men were taken prisoners and the rest retreated over Cheat Mountain. McClellan pursued through Beverly and Huttonsville, seized the summit of Cheat Mountain and entrenched a part of his command on the main Staunton turnpike leading over the mountain. (See RICH MOUNTAIN, BATTLE OF). Garnett, who was at Laurel Hill, abandoned his position on the night of the 11th and retreated northeast

toward the Northwestern turnpike, was overtaken at Carrick's Ford, on Cheat River, on the 13th, was killed and his command, making a rapid retreat, reached the Northwestern turnpike and turning southward arrived at Monterey in a demoralized condition. There are but three routes across the mountains separating West Virginia from the Shenandoah Valley that are practicable for military operations: the Northwestern turnpike on the north; the Staunton and Parkersburg turnpike farther south and the Kanawha turnpike, leading past Gauley Bridge, still farther south. While McClellan was seizing the two first, a column under General Cox was operating on the latter. At the time General Garnett was sent to Rich Mountain, Gen. H. A. Wise was ordered to raise a force for the defense of the Kanawha Valley and Gen. J. B. Floyd was directed to raise a brigade for service in southwestern Virginia. It had been McClellan's intention to conduct his campaign in West Virginia by way of the Kanawha Valley, but the gathering of the Confederates near Beverly determined him to proceed to that region and postpone his Kanawha campaign till northwestern Virginia should be cleared of the enemy. Later it was found that the presence of Wise in the Kanawha Valley menaced his flank and 2 July General Cox, with a brigade, was ordered to cross the Ohio at Gallipolis and conduct a campaign against Wise, and on the 6th he was ordered to march on Charleston and Gauley Bridge. Cox crossed the Ohio, with about 3,000 men, drove in some of Wise's advanced detachments and on 11 July moved up the Great Kanawha River in transports. The river was navigable for small steamers about 70 miles, to a point 10 or 12 miles above Charleston, the only important town of the region which is at the confluence of the Kanawha and Elk rivers. On the evening of the 16th Cox reached the mouth of the Pocotaligo, a large creek which enters the Kanawha from the north, where he heard that some of Wise's forces were in position above the mouth of Scarey Creek on the south side of the Kanawha and about three miles distant. It was necessary to dislodge this force before he could proceed farther. Troops were landed on the south side of the river, on the 17th, and the position was attacked, but Cox's men were repulsed with a loss of 14 killed and 47 wounded. (See SCAREY CREEK, ENGAGEMENT AT). This check delayed Cox until he could get land transportation, which came on the 23d, and the next day he advanced, took Charleston on the 25th, which Wise had hurriedly abandoned, and on the morning of the 29th reached Gauley Bridge. Wise retreating before him and not halting until he reached Greenbrier and the White Sulphur Springs, where he was joined by General Floyd. The whole of West Virginia, with the gateways to the East were now in Union possession, but the Confederates did not let the possession go unchallenged and made efforts to recover the lost ground.

After the defeat and death of General Garnett, Gen. W. W. Loring was ordered to the command of the Confederate forces in northwestern Virginia, and being strongly reinforced began preparations to retake Cheat Mountain. Before these preparations were completed, Gen. R. E. Lee was assigned to the command of all the Confederate forces in West Virginia and

August joined Loring at Valley Mountain where he remained a month, making him acquainted with the country, bringing up equipments and supplies and elaborating a plan of campaign by which he proposed to break through the Alleghenies and recover the country to the Ohio. His point of attack was a position covering Beverly and the westward. McClellan had been called to action, leaving General Rosecrans in command of the Union troops holding the Cheat Summit and one by the Lewisburg Intersville road against Elk Water. At the same time another column was ordered to pierce between Elk Water and Cheat Summit, a distance of eight miles through a trackless forest, to gain the rear of both positions. The movement began on 11 September, but Lee's command succeeded in reaching the rear of the Union troops at the summit, backed by the Staunton road in front and were repulsed. The column sent against Beverly appeared before that position but, because of the failure of the other columns, made no advance and on the 15th all the columns retired to their old positions. Lee was greatly disappointed and deeply mortified at his failure and ordered a cloud from which he did not emerge till after he had succeeded to the command of the Army of Northern Virginia, in 1862. No further effort was made by the Confederates to regain the ground lost in the east, nor was a general Union advance attempted, but there were sharp encounters at Bartow and Camp Alleghany (qq.v.), resulting in Confederate success. Lee and Wise, who had united forces near Staunton, moved forward in the middle of September to Sewell Mountain and on the 23d crossed to the north side of Gauley River and crossed Fairfax Ferry to flank Cox at Gauley Bridge and drive him down the Kanawha Valley to the Ohio. He attacked and defeated the Union at Cross Lanes, on the 26th, and on September 27 was attacked by General Rosecrans that night recrossed the Gauley and drove back to Sewell Mountain. (See CARNIFAX.) After some delay Rosecrans advanced to the top of Big Sewell Mountain, 34 miles from Gauley Bridge and began skirmishing with the Confederates. Lee, with a part of his command, joined Floyd on 29 September and assumed command. The two positions that lay opposite each other upon the north side of Big Sewell, separated by a deep gorge, about equal in number, but each commander had exaggerated ideas of the strength of the other and it was difficult for either to make an offensive move. Each was looking for a change in his adversary's position, using extraordinary energy to feed the men and animals and waiting for the rains to cease and the roads to dry. But the rains did not cease, and there was an extraordinary rise in the waters of the Kanawha. On the night of 5 October Rosecrans began to retreat and at the end of four days his army was in camp between Hawks' Nest and Gauley Bridge. When Lee discovered that his army had gone he ordered the cavalry to follow; when satisfied that he had gone clear to

Gauley Bridge he began repairing the road from Sewell Mountain to Lewisburg and projected a campaign for Floyd down the left bank of New River and then to the mouth of Loop Creek, the head of navigation of the Kanawha, to intercept Rosecrans' communications, while an effort was being made to press him in front. Floyd lost no time in preparing for the movement to drive Rosecrans from Gauley Bridge back to Charleston, probably to the banks of the Ohio. On 10 October he started and after a difficult march over mountain roads, crossed New River at Richmond Ferry and toiled on over the Raleigh, Fayette and Kanawha turnpike, through Fayetteville, and on the 22d camped on Cotton Hill, five miles beyond Fayetteville, in the elbow south of the junction of the New and Gauley rivers. On the next day he wrote the Confederate Secretary of War that with a proper force he could dislodge Rosecrans from Gauley Bridge and drive him back to Clarksburg, with 10,000 additional men he would win the whole Kanawha Valley before the conclusion of the campaign. Meanwhile Lee had informed him that Loring's troops would march back to the Cheat region, and this settled the fact that he would have to measure strength with Cox unaided by any advance on the Lewisburg road. On 1 November he opened on Rosecrans with artillery. Rosecrans planned to capture him, and on the 12th Floyd retreated, narrowly escaping capture. (See GAULEY BRIDGE.) The campaign on the Kanawha, as in the Cheat region, was ended. The inclement weather rendered extended movements impracticable and both Union and Confederates found ample employment in getting up supplies, maintaining the roads in condition, providing shelter and guarding against surprise. Scouting was restricted to narrow limits and the results were unimportant. But the campaign had been one of the greatest importance. The whole line of the Alleghenies, from the Pennsylvania border on the north and beyond the Kanawha on the south, was securely guarded against incursions from the east, and westward to the Ohio River, western Virginia was in the hands of the Union government. The political transformation of West Virginia kept pace with the military movements, finally resulting in a new State. Consult 'Official Records' (Vols. II, V); The Century Company's 'Battles and Leaders of the Civil War' (Vol. I); Cox, 'Military Reminiscences of the Civil War' (Vol. I).

E. A. CARMAN.

**WEST VIRGINIA AND MARYLAND BOUNDARY DISPUTE.** The principal dispute was an old one in regard to the meaning of the "first source of the Potomac" which in Lord Baltimore's charter was mentioned as a point from which to determine the boundary of western Maryland. This was marked in 1746 by the Fairfax Stone at the head of Fairfax Run, which was regarded as the head of the North Branch, in accord with a decision of a council based upon a careful survey by a boundary commission. Although in 1852 Maryland finally accepted the Fairfax stone as a point marking the meridian of her western boundary, in 1859 she secured a new survey of the meridian line northward which terminated at the Pennsylvania boundary about three-fourths of a mile west of the old line (surveyed in 1788)

thus laying the basis of later controversies with West Virginia in regard to conflicting land claims and jurisdiction in the triangular strip between the two lines—some of which culminated in personal encounters and breaches of the peace which each State treated as a crime within its jurisdiction and attempted to punish.

In the suit begun against West Virginia in 1890, Maryland, besides claiming that the source of the North Branch should be located nearly a mile west of the Fairfax stone, also injected the old claim to the South Branch as the farthest source of the Potomac—a claim which would have divided West Virginia into two non-contiguous parts. The court decided both of these questions in favor of West Virginia on the basis of prescriptive right arising from long-continued possession of people claiming rights on the West Virginia side of the long-recognized line. Maryland also claimed that the rights of Lord Baltimore included the bed of the Potomac to high-water mark of the southern shore. The court, however, decided that, consistent with long-continued exercise of political jurisdiction, the uniform southern boundary of Maryland was at low-water mark on the south bank of the river to the intersection of the north and south line forming the western boundary of Maryland. The survey and marking of the boundary in accord with the court decision was accomplished by a joint commission in 1912.

JAMES M. CALLAHAN,

*Professor of History and Political Science,  
West Virginia University.*

**WEST VIRGINIA UNIVERSITY**, a co-educational State institution located at Morgantown, 100 miles south of Pittsburgh. The university grounds, with a picturesque outlook upon the adjacent Monongahela River, have an attractive natural site equaled by few institutions of learning. The campus contains about 50 acres.

The university originated from the national land grant act of 2 June 1862, and from the subsequent action of the State legislature in accepting and carrying out the provisions of the act. Its location at Morgantown was largely determined by the foundation of an educational institution which had already been laid at Morgantown through an academy first established in 1814 and re-established in 1832. On 30 Jan. 1867, the legislature accepted the property of the old Monongalia Academy and on 7 February passed an act permanently establishing "The Agricultural College of West Virginia" and authorizing the governor to appoint a Board of Visitors which at their first meeting on 3 April 1867 appointed the first president and established "collegiate, scientific and agricultural" departments of instruction. A department of military science was organized soon thereafter. By an act of 4 Dec. 1868, the name of the college was changed to "West Virginia University" and the close corporation "Board of Visitors" to the "board of regents," which in 1895 became bipartisan and rotary. The original college (Arts and Sciences) began in 1867 with five departments which by differentiation and expansion increased to more than 25 by 1907. After the original college, other colleges and schools were established as follows: the College of Law 1878; the College of Engineering, 1887; the College of Agriculture,

1897; the School of Music, 1897; the School of Medicine, 1902. The agricultural experiment station was established in 1888 and is now under the direction of the dean of the College of Agriculture. The division of agricultural extension was organized in 1912.

For many years the growth of the new institution was very slow and uncertain, largely due to old sectional questions, new post-bellum political questions and the lack of a satisfactory system of secondary schools.

Gradually the obstacles to growth were reduced or removed by changing conditions. Industrial progress, stimulating better communication, was a prominent factor in the transformation of the earlier poorly-equipped school into a real college which may now claim university rank. The first remarkable increase in attendance was coincident with the admission of women between 1889 and 1897, after a long struggle against conservative opposition. In the last decade it has had phenomenal growth, greatly aided by the development of better secondary schools, and is worthy of recognition as one of the leading State institutions. A preparatory school which throughout the earlier years was maintained in connection with the university, was abolished in 1912.

In recent years the curriculum and many of the courses have been readjusted to the new needs resulting from rapidly changing conditions of life. Students are admitted either by examination or on certificate (detailed statement of work) from an accredited preparatory school. Entrance requirements are 15 units (four years of high-school work) with liberal provision for electives. The time required for completion of baccalaureate degrees is four years. Ancient language requirements for graduation in the A.B. course were recently abolished. By a combination of academic and professional work a student may earn the regular university degree and the professional degree in six years.

The problem of securing suitable buildings to meet the needs of expansion and more efficient instruction has been a continuous one. There are now eight main buildings, several with annexes, besides several temporary frame buildings, used for classrooms. A modern library building was completed in 1902. The most recent modern building (Oglebay hall) was completed in 1919 for use by the College of Agriculture. A new building for the College of Law was erected in 1919-20. Buildings and grounds and equipment were valued in 1919 at approximately \$2,600,000.

Equipment, which in the earlier days was scarce and poor, has recently been provided liberally. Laboratories are equipped for conducting modern scientific work. The general library contains over 60,000 volumes.

The annual income of the university and experiment station from all sources for the year ending July 1919 was approximately \$934,000.

A special feature since 1902 is the Summer School which is meeting the needs of many students who cannot attend during the regular semester.

Recently more attention has been given to advanced courses suitable for graduate work. The master's degree may be completed in an additional year (36 weeks) of advanced study

dence after completion of the baccalaureate degree. The degree of Ph.D. is not earned, but graduate work applicable to this degree may be pursued for certificates at other institutions which give their attention to graduate instruction. Research is steadily developing in all colleges.

The total number of students in 1911-12 was 9, of which 449 were candidates for degrees. The total enrolment in the year 1918-19 (including the School of Music and various courses) was 1,305, of which 1,281 were candidates for degrees (and 379 were women). The total enrolment in the College of Arts and Sciences was 681, of which 314 were candidates for degrees.

That of the College of Engineering was 130 (of which 59 were women); of the College of Agriculture 45 (5 were women); and of the School of Medicine 45 (5 were women). The enrolment of the Summer School was 681 in 1919.

In 1911-12 the total number of the instructional force (exclusive of assistants, library and experimental station staff) was 68, of which 37 were full professors. In 1918-19 it numbered a total of 118 including 47 professors, 20 associate professors, 20 assistant professors and 13 instructors.

In 1909 the financial and business affairs of the university (and of other State educational institutions) was placed under the direction of a State board of control, consisting of five members appointed by the governor. The control remained in a bipartisan board until 1919 consisted of the superintendent of free schools (ex-officio) by the people, and of four other members appointed by the governor, but which in 1919 was merged into the State board of education consisting of seven members including the superintendent.

West Virginia University.*

**WEST VIRGINIA AND VIRGINIA DEBT QUESTION.** The Virginia debt question arose with the formation of West Virginia. It has been a prominent factor or issue in the politics at various times. At the time of separation from Virginia, the new State constitution agreed to assume a just proportion of the public debt of Virginia prior to 1862 to be ascertained by charging to it all the expenses within the limits thereof and a proportion of the ordinary expenses of the government, since any part of said debt contracted, and deducting therefrom all amounts paid into the treasury of the commonwealth from the counties included within the new State, during the same period." As early as 1866, and again in 1870, Virginia appointed commissioners with authority to negotiate an adjustment of the debt. A West Virginia commission failed to act in 1870, because no appropriation was provided for it. In 1871, it declined the proposal of a new policy of arbitration by commission to the citizens of either State. Acting on the examination of documents at Richmond, however, it reported a net credit of \$1,223,000 in favor of Virginia—a conclusion which the West Virginia legislature did not ac-

cept. In 1873 a new consideration by the West Virginia Senate finance committee, whose chairman (J. M. Bennett) had been auditor of Virginia for eight years, resulted in a report of \$525,000 in favor of West Virginia, which became the basis of public opinion in the new State thereafter.

Meantime, by act of 1871, Virginia funded two-thirds of the debt, and for the remaining third gave certificates making her liable only in accordance with future settlement with West Virginia. Later she released herself from all liability for the one-third by certificates of 1879, 1882 and 1892 which were placed upon the market under the name "West Virginia certificates."

After compromising and settling with her creditors and securing release from all liability, she provided in 1894 for the appointment of a commission (of seven members) which in 1895 and 1896 unsuccessfully proposed negotiations with the West Virginia on the basis that Virginia was liable for only two-thirds of the old debt. In 1900, as trustee of the certificate holders, she again proposed adjustment on conditions which West Virginia declined to accept.

Later, Virginia instituted a suit for settlement under supervision and direction of the United States Supreme Court, which, in 1908, appointed a special master of accounts to take evidence for later presentation. The Supreme Court, before which the final arguments were presented in January 1911, promptly rendered a decision tentatively fixing West Virginia's share of the old debt at \$7,182,507.48 and leaving the question of interest for later adjustment. West Virginia then created a "Virginia Debt Commission" to reduce the amount, if possible, preparatory to contingent arrangements for payment. On 14 June 1915 the court issued a judgment against West Virginia for \$12,393,929.50 including accrued interest, and for 5 per cent interest thereafter until paid.

In June 1916, Virginia asked the Supreme Court for a writ of execution by levy upon public property of West Virginia. This the court denied for the time in order first to give the West Virginia legislature a "reasonable opportunity to provide for the payment of the judgment." In February 1917, Virginia filed application for a writ of mandamus against the legislature of West Virginia to compel the levy of a tax to pay the judgment. The court, although (in April, 1918) it deferred action, indicated that appropriate remedies for enforcement could be found, both in the power of Congress and in the power of the judiciary under existing legislation, in case West Virginia should fail to do her duty. On 1 Jan. 1919, the amount of the debt was \$14,562,867.16. Of this amount, West Virginia, by act of 31 March 1919, arranged to pay \$1,062,867.16 in cash and the balance by an issue of "listable" 3½ per cent bonds (coupon and registered) payable in 1839 (or earlier). Consult Ambler, C. H., 'Sectionalism in Virginia' (1910); Fast, R. E., and Maxwell, H., 'History and Government of West Virginia' (1908); Callahan, J. M., 'Semi-Centennial History of West Virginia' (1913).

**WEST WIND DRIFT.** See **CURRENTS, OCEAN.**

**WESTALL, Richard,** English painter: b. 1765; d. London, 4 Dec. 1836. He was apprenticed in London to an engraver on silver in 1779; subsequently studied at the schools of the Royal Academy and began to practice his art in association with Thomas Laurence in Soho Square. Here he became very popular as an illustrator of books and for a single design in water colors sometimes received \$400 or \$500. He also painted historical subjects. His 'Elijah Restoring the Widow's Son to Life' was purchased for some \$2,250 by the directors of the British Institution; but his paintings in oil were not generally salable; his designs and figures are monotonously conventional, although some of his scenes from peasant life are by no means destitute of freshness and charm. One of his last occupations was that of teaching drawing to Princess afterward Queen Victoria of England. His water-color painting, 'Cassandra Propheying the Fall of Troy,' is in the South Kensington Museum, and his pictures in oil of 'Christ Crowned with Thorns' in All Souls' Church, Langham Place, London.

**WESTALL, William,** English novelist: b. White Ash, Lancashire, 7 Feb. 1834; d. 9 Sept. 1903. He was educated at the Liverpool High School, engaged in business and in journalism and was foreign correspondent for the *London Times* and *Daily News*, traveling in North and South America and in the West Indies. He has been a prolific writer and among his publications are 'Tales and Traditions of Saxony and Lusatia' (1877); 'In Tropic Seas' (1878); 'Harry Lohengrin' (1879), and 'The Old Factory' (1881); 'Red Ryvington' (1882); 'A Queer Race'; 'A Phantom City.'

**WESTBORO, Mass.,** town in Worcester County, on the Boston and Albany Railway, 12 miles east of Worcester, 32 miles west by south of Boston. It contains five churches, a public library with 18,000 volumes, the Westboro Insane Hospital, the Lyman Reform School, a savings bank, a national bank, a weekly newspaper and numerous important manufacturing industries, the chief being those connected with straw and leather goods, boots and shoes and automobiles. Westboro was settled about 1659, and at first known as Chauncey, but in 1717 it was incorporated under its present name. It is the birthplace of Eli Whitney (q.v.), inventor of the cotton gin. Pop. 5,925.

**WESTBROOK, Maine,** city in Cumberland County, on the Presumpscott River and on branches of the Boston and Maine and the Maine railroads, six miles west of Portland, with which it is connected by electric lines. The river furnishes considerable water power, which is utilized by manufactories, chief of which are silk and cotton mills, paper and flour mills and machine shops. The silk and cotton products are mainly dress goods, cotton warp and seamless bags. The manufacturing interests include some 42 establishments, with over 1,500 employees and an annual production of \$3,500,000. The city has eight churches, the Presentation Convent, a high school, public and parish elementary schools, the Walker Memorial Library, a bank and a newspaper. A city govern-

ment was inaugurated in 1891. Pop. about 8,281.

**WESTBURY, Richard Bethell, BARON,** English jurist and statesman: b. Bradford-on-Avon, Wiltshire, 30 June 1800; d. London, 20 July 1873. Graduated from Oxford in 1818, he was admitted to the bar at the Middle Temple in 1833, in 1852 became solicitor-general, and in 1856-58 was attorney-general under Lord Palmerston. This post he held a second time, in 1859-61 and in 1861 he became lord high chancellor of Great Britain. As chancellor he did much by his decisions to aid the development of British equity jurisprudence, especially so in joint stock company law, ecclesiastical appeals and patent law.

**WESTCOTT, wĕst'kòt, Brooke Foss,** English bishop and theologian: b. Birmingham, January 1825; d. Bishop Auckland, 27 July 1901. He was graduated from Trinity College, Cambridge, in 1848, was elected a Fellow of his college in 1849 and in 1851 was ordained in the English Church. He was assistant master at Harrow 1852-69, and here he remained till 1869, when he became a residentiary canon of Peterborough. He became canon of Westminster in 1883 and on the death of his friend, Lightfoot, bishop of Durham, was appointed his successor in 1890, and in this see he remained until his death. He showed a deep interest in the lot of the miners in his diocese, which won him their genuine esteem, and he was very successful in preventing and settling industrial disputes. From 1870 to 1890 he was regius professor of divinity at Cambridge and during his tenure of the office exercised a powerful and abiding influence on undergraduates and scholars. As a scholar and theologian Westcott's position was a very high one. As a textual critic he is best known for his share in the revision of the Greek text of the New Testament, which occupied him and J. F. A. Hort for 28 years, and resulted in the publication of their important work, 'The New Testament in the Original Greek,' in 1881. The text formed the basis of the Revised Version of the New Testament. His other published works include 'General Survey of the History of the Canon of the New Testament During the First Four Centuries' (1855), which has gone through many editions; 'Introduction to the Study of the Gospels' (1860); 'A General View of the History of the English Bible' (1868); 'The Paraphrase Psalter' (1879); 'The Revelation of the Risen Lord' (1882); 'Social Aspects of Christianity' (1887); 'Essays in the History of Religious Thought in the West' (1891); 'The Gospel of Life' (1892); 'The Incarnation and Common Life' (1893); 'Lessons of the Revised Version of the New Testament' (1894); 'Christian Aspects of Life' (1895); 'Lessons from Work' (1901), and 'Words of Faith and Hope' (1902). He was one of the New Testament revision company. Consult 'Life,' by his son (1903).

**WESTCOTT, Edward Noyes,** American novelist: b. Syracuse, N. Y., 27 Sept. 1847; d. there, 31 March 1898. He was a banker in his native city, but compelled to retire because of failing health, spent the winter of 1895-96 in Italy and in the latter year completed the novel

Harum,' which he had begun soon is retirement from business. It was de- by many leading publishers, but when in the autumn of 1898, six months after thor's death, became at once a success, g a sale of 400,000 copies in a little more year. The human nature of the book strong characteristic; it is a faithful re- of certain phases of life in central New d its humor is undeniable.

**WESTERLY, R. I.**, the largest town in the outh of Providence, in Washington ; on the Pawcatucket River, and on the ranch of the New York, New Haven, Hartford Railroad. It is in the south- n part of the State, and near Long Island ishers Island sounds. The first white ; came from Newport, and for a while e Indian name, Misquamicut. For a time also known as Southernton. On 14 May it was incorporated under the present

In 1686 it changed its name to Haver- and in 1689 it was again renamed, West- The town contains five villages, each with n post office. The chief manufacturing ies are cotton, wool and silk mills, presses and thread. The granite quar- ...ong the largest in the country, have the name "Westerly Granite" known the over. The summer resort Watch Hill, the villages of the town, has a summer tion of 3,000. Other summer resorts the town limits are the beaches known antic Beach and Weekapang. The town ght churches, a Federal post office and a courthouse. The public library, "The c Memorial Library," a heavily en- institution, is one of the best in New id. There are two banks with deposits ut \$6,000,000. Pop. about 10,075. Con- lenison, 'Westerly and Its Witnesses'; n, 'Early Rhode Island' (1910); also s publications of the Westerly Historical y.

**WESTERMARCK, Edward Alexander**, h anthropologist; b. Helsingfors, 20 Nov. He was educated at the Lyceum at gfors, and at the University of Finland. s appointed professor of moral philosophy University of Helsingfors in 1894; was d in travel in northern Africa in 1898- studying the moral conditions of the ive races; and in 1907 was appointed pro- of sociology at the University of Lon- He also lectures frequently at the Uni- of Helsingfors. His book 'The His- f Human Marriage' (1891) went through l editions and was translated into French, Spanish, Swedish, Russian, German and se, and gained for him a world-wide tion. He is also author of 'The Origin velopment of the Moral Ideas' (2 vols., 8); 'Marriage Ceremonies in Morocco' l, etc.

**WESTERN AUSTRALIA**, one of the of the new Commonwealth of Australia. USTRALIA, WEST.

**WESTERN EMPIRE**, The, the western of the Roman empire, consisting of Illyricum, Spain, Gaul, Britain and s, as distinguished from the Eastern or time empire, comprising the eastern half

of the Balkan Peninsula, Greece, Egypt, Syria and Asia Minor, so for as Persia. This parti- tion of the Roman empire occurred in 364 when Valentinian I shared the imperial authority with his brother Valens, who ruled in Constantinople as emperor of the East, while Valentinian ruled in Rome as emperor of the West. The partition became final in 395 when Theodosius the Great divided the Roman world between his two sons Honorius, who became emperor of Rome and the West, and Arcadius, who became emperor of Constantinople and the East. The Western empire terminated in 476. See BYZANTINE EMPIRE; ROME.

**WESTERN FEDERATION OF MINERS** (since December 1916 known as the *International Union of Mine, Mill and Smelter Workers*), a labor organization of persons working in mines, mills and smelters, founded 15 May 1893, at Butte, Mont., and hav- ing for its object the general improvement of its members, the abolition of child labor, govern- ment by injunction, etc. The executive board is made up of a president, vice-president, secre- tary-treasurer and four organizers. This board passes on all joint contracts to which local unions are a party, on every strike and acts as a board of arbitration when occasion offers. It directs the federation except during the bi- ennial convention, when the latter is supreme. The Federation resulted from the strike of 1892 at Cœur d'Alene. It was involved in an- other strike there in 1899, in which the struggle between operators and miners became most bitter. In 1896-98 it was affiliated with the American Federation of Labor, and thereafter to 1905 with the American Labor Union. It helped form the Industrial Workers of the World in 1905, but withdrew in 1906. In 1911 it again joined the American Federation of Labor. The mem- bership is not bound by any political party or platform. The *Miners' Magazine* is the official publication.

**WESTERN ISLANDS.** See AZORES; HEBRIDES.

**WESTERN MARYLAND COLLEGE**, located at Westminster, Md. It was founded under the auspices of the Methodist Protestant Church, and was first opened to students in 1867. It was the first college in the South to offer equal educational privileges to both sexes; but it is not strictly co-educational, as there are separate classes for women, though they are taught by the same instructors and have practically the same courses of study as the men. The courses of study are arranged in three groups, which are practically the same in the first two years, but differ in the last two, and in accordance with the predominating study are known as the classical, the scientific and the historical. The degree of A.B. is conferred for the completion of a four years' course in any of these groups. In addition, courses are offered in music, art and elocution, and students who complete one of these courses may substitute it for certain studies of the junior year. There is also a pre- paratory school which in 1899 was established in a separate building (Levine Hall) a short distance from the campus. There are two State scholarships for each senatorial district. The campus contains 14 acres situated on elevated ground in the western part of the city. The

main building consists of a central part, the original building and five wings: (1) Owings Hall, extending back from the central part; (2) Smith Hall, extending to the east; (3) Hering Hall, extending to the west; (4) Ward Hall, a rear extension of Hering Hall, and (5) a rear extension of Smith Hall. Other buildings are the Yungling Gymnasium, Y. M. C. A. Hall, Baker Chapel, built of white stone, and Alumni Hall, containing a large assembly room, the halls of the literary societies, etc.

**WESTERN PORT, Md.**, town in Alleghany County, on the north branch of the Potomac River, 20 miles southwest of Cumberland, and on the Western Maryland Railroad. It is situated in a coal mining district, and there are paper factories. Pop. 2,702.

**WESTERN RESERVE, or CONNECTICUT RESERVE**, that portion of the Northwest Territory (q.v.) reserved by Connecticut when, in 1786, that State ceded to the United States other parts of the territory claimed under the charter of 1662, which granted to Connecticut lands limited east and west by the sea. This section of land is what is now included in the northeastern part of Ohio; it was all the territory between lat. 41° and 42° 2' N., and extending 120 miles from the western boundary of Pennsylvania. In 1795-96 Connecticut sold this land, except 500,000 acres, to a number of men who established what was known as the Connecticut Land Company. At first settlers hesitated about purchasing any of the land on the "Reserve," fearing the validity of the title, but when the State of Connecticut yielded all claim to the government, there was no longer any doubt about the titles. There were a large number of colonists from Connecticut who settled on this "Reserve," counties were organized, 13 in all, which were in whole or in part from lands of the "Reserve." (See **NORWALK, OHIO**). The people were characterized by their thrift, industry and the manner in which they established schools. A large part of the money received by Connecticut for the sale of the lands was set aside "as a perpetual fund, the interest of which should be appropriated to the support of schools." This school fund was the means of influencing in Ohio a unique system of education, in some respects different from that of any other State. Consult Matthews, 'Ohio and Her Western Reserve' (1902).

**WESTERN RESERVE UNIVERSITY**, located at Cleveland, Ohio, includes the College for Women, the Graduate School, the Medical School, the Law School, the Dental School, the Library School, the School of Pharmacy, the School of Education (summer sessions) and the School of Applied Social Sciences. As a working, though not a corporate, part of Western Reserve University is Adelbert College of Western Reserve University. Adelbert College of Western Reserve University was founded as Western Reserve College in Hudson, 26 miles from Cleveland, in 1826. As the territory formerly belonged to Connecticut, and derived its name from being territory in the West reserved for special purposes, so also the influence of Connecticut's great college dominated in its establishment and during its first decades. In affiliation with the college at Hud-

son for many years was the Cleveland Medical School. Theological instruction was also given for many years, ceasing in 1853. In 1882 Western Reserve College was moved to Cleveland Amasa Stone (q.v.) gave to the college the sum of \$600,000. In recognition of the gift the college took the name of a beloved son of Mr Stone, who died while a student at Yale, becoming Adelbert College of Western Reserve University. Subsequent gifts and bequests, together with gifts made by members of his family, have amounted to more than \$1,100,000. In 1884 a university charter was obtained. The following departments, in addition to the Medical School, were established: In 1888 the College for Women, in 1892 the Dental School, the Law School and the Graduate School, in 1903 the Library School, in 1882 the School of Pharmacy, in 1915, the School of Education and the School of Applied Social Sciences. The Library School was endowed by a gift of \$100,000 made by Andrew Carnegie.

The college and the university have throughout their history been distinguished by a high type of scholarship. Among the professors have been Rev. Laurens Perseus Hickok, 1836-44; Rev. Clement Long, 1844-52; Nathan Perkins Seymour, 1840-70; Elias Loomis, 1836-44; Charles Augustus Young, 1856-66; Elijah Porter Barrows, 1837-52; Samuel St. John, 1838-52; Samuel Colcord Bartlett, 1846-52. Its presidents have been Charles Backus Storrs, 1830-33; George Edmond Pierce, 1834-55; Lawrence Hitchcock, 1855-71; Carroll Cutler, 1871-86; Hiram Collins Haydn, 1887-90. Charles Franklin Thwing has been president of the university since 1890. The whole number of students in the different departments, from the beginning, has been as follows: Adelbert College, 3,545; The College for Women, 2,500; the Graduate School, 400; the School of Medicine, 5,200; the Law School, 1,800; the Dental School, 700; the Library School, 496; the School of Education (summer sessions) 2,781; the School of Applied Social Sciences, 329 (including students in extension courses). The buildings and equipment are valued at almost \$4,000,000 and the entire property \$8,000,000.

In the fall of 1918, there was begun the erection of a new Gymnasium Armory. This building is 175 feet in length by 90 feet in width.

In the general educational endeavor known as Western Reserve University are two administrative features of special significance. One lies in the co-ordinate method of education. A college for men, Adelbert College, and a college for women exist as essential members of the same university. Each has its own faculty and government. The two bodies of students are distinct. Each college has its endowment and buildings. The work in the sciences, however, is done in the same laboratories, but usually at different times. Professors in the same departments of the two institutions exchange courses of instruction to a certain extent. The co-ordinate method is in part a co-operative method. In a State and a part of the country noted for co-education, the method prevailing in Western Reserve University is conspicuously successful. A further significant method of administration relates to the co-operative course of study established be-

the Case School of Applied Science and Art College. These two institutions are upon the same campus and each has its board of trustees. But the two faculties arranged a course of instruction covering arts, three of which are spent in pursuing liberal studies of the undergraduate college (Adelbert College) and the last two years in the technical school (Case School of Applied Science). At the conclusion of the four-year course a bachelor of arts and a bachelor of science degree are given. Thus, the advantages of the liberal course of study are secured and the efficiency of the specialized course is also gained.

Students also may have the privilege of continuing the course in Adelbert College with the course in the Law School or the School of Medicine of Western Reserve University. The course in arts and law covers six years. The course in arts and medicine takes four years. Both the Law School and the School of Medicine are graduate schools. In the combined courses one year of time is saved. With the beginning of the academic year 1918-19, women were received into the school. Previous to this time, the courses were open only to men.

**WESTFIELD**, Mass., town in Hampden County, on the Westfield River, and on the borders of Massachusetts and Albany, and the New York, New Haven and Hartford railroads, nine miles west of Springfield. It is on the site of an Indian village which was called Woronoco. The chief manufacturing establishments are machine shops, paper mills, thread mills, motorcycle, leather and whip factories, and cigar factories. The town has nearly 200 factories employing 3,500 persons, with annual output of about \$7,500,000. The valley in Westfield is located is noted for its beauty; the town has a park, Woronoco, an artesian water-supply, which is brought from Mt. Tom, seven miles distant, and a sewerage system. The water plant, completed in 1874, cost nearly \$250,000. There are seven churches, the Noble Hospital, the Massachusetts State Normal School, a public school, established in 1855, public and elementary schools, kindergartens, and a library, which contains over 25,000 volumes. There are four banks, and a daily and weekly newspaper. Pop. 18,411.

**WESTFIELD**, N. J., village in Union County, on the Central Railroad of New Jersey, 30 miles southwest of New York. It is a residential village, in a beautiful location on an elevation. There are six churches, and private schools, two newspapers and two banks. Pop. 8,147.

**WESTFIELD**, N. Y., village in Chautauque County, on the Chautauque Creek, and on the New York, Chicago and Saint Louis and the Michigan and Southern railroads, 50 miles southwest of Buffalo, and 20 miles southwest of Dunkirk. It is in an agricultural and fruit region, in which the chief products are grapes, apples, peaches and pears. There are railroad shops, a grist-mill and fruit-and crate factories. There are six schools, a union school and academy, which has two endowed scholarships, and a public

library, founded by Hannah Patterson by a gift of \$100,000. There is a national bank and a newspaper. Pop. about 2,985.

**WESTFORD**, Mass., town in Middlesex County, on the Boston and Maine Railway, 6 miles southwest of Lowell. It contains several villages, and has four churches and a public library. There are manufactures of woolen goods and machinery, and agriculture and granite quarrying are carried on. Pop. about 2,851.

**WESTINGHOUSE**, George, American inventor: b. Central Bridge, N. Y., 6 Oct. 1846; d. New York, 12 March 1914. He entered the machine shop of his father, a manufacturer of agricultural implements, when very young and early evinced an inventive genius, designing at 15 a rotary engine. He served in the Union army in 1863-64, and in 1864-65 was assistant engineer in the United States navy, after which he studied at Union College for two years. He continued his interest in mechanics, his first invention of importance being a railway frog. In 1868 he introduced the famous Westinghouse brake (see AIR-BRAKE), which has since been developed to a remarkable degree of efficiency, and has come into international use. At first his invention was scouted as impracticable. The story is told that he interviewed Commodore Vanderbilt, and explained his designs. The Commodore is said to have replied, "If I understand you, young man, you propose to stop a railroad train with wind; I have no time to listen to such nonsense." A few years later the "impossible" device was operating on all the Commodore's lines. Mr. Westinghouse was one of the pioneers in introducing alternating-current machinery, and he succeeded in securing the use of this method at the Chicago Exposition in 1893. He has also made numerous improvements in railroad signaling, and through his devices the safety of high-speed railway traveling has been greatly increased. He erected extensive works in this country and abroad for the manufacture of his various inventions, was president of over 30 corporations and proved to be as good a business man as he was a skilled mechanic. He received the Order of Leopold from the Belgian king in 1884, and in 1889 the Royal Order of the Crown from the king of Italy. He was also decorated with the French Legion of Honor. Consult Leupp, F. E., 'George Westinghouse: His Life and Achievements' (Boston 1918).

**WESTLAKE**, Nathaniel Hubert John, British painter, designer and writer in art: b. Romsey, 1833. He studied at Lee's, at Somerset House, under Dyce and Herbert, at the British Museum, and also at Antwerp and Paris. At the suggestion of the late W. Burges he went to a firm of glass painters to design, and afterward became art manager and partner of the firm about 1880. He has frequently exhibited at the Royal Academy, Arts and Crafts, etc. His paintings are in Saint John's Church, Richmond, Portsmouth Cathedral, Saint Augustine's, Tunbridge Wells, Bute Memorial Chapel, Cardiff Castle, Wales, the Chapel of Maynooth College, Ireland. Mr. Westlake designed glass for Saint Paul's Cathedral, London, the cathedrals of Peterborough and Wor-

cester, the Gate of Heaven Church, South Boston, Mass., the Via Crucis of Saint Francis's, Notting Hill, London. He designed Salvati's mosaic of Blessed James of Ulm at the South Kensington Museum, London, the apse mosaic in the Newman Memorial Church, Birmingham, and has collaborated with many famous architects. His publications include 'Outlines of the History of Design in Mural Painting' (3 vols.); 'History of Painted Glass' (4 vols.); 'True Portraiture of St. Francis'; 'Sketches at Malines Exhibition.' He edited 'Reproduction of Royal Manuscripts, 2 B VII, British Museum'; 'Queen Mary's Psalter,' etc.

**WESTLAKE, William,** American inventor: b. Cornwall, England, 23 July 1831; d. Brooklyn, N. Y., 28 Dec. 1900. He came to the United States in 1847, settled in Milwaukee, Wis., and there was employed in a printing office. He was subsequently an apprentice to a tinsmith, and in 1853 made for Captain John Ericsson the models for his first hot-air engine. He entered the employ of the La Crosse and Milwaukee Railroad Company in 1857, and soon after began the series of inventions which made him famous. Among them are the Westlake car heater, the globe lantern, the first practical car lamp, the oil cook stove, the stove-board, etc.

**WESTLAND,** New Zealand, a provincial district in South Island, bounded north by Nelson district, south by Otago, west by the ocean and east by Canterbury, from which it is separated by the chain of the Southern Alps. It is about 200 miles long and about 25 miles in average breadth, its area being about 4,642 square miles. It consists principally of hills branching off from the great alpine system, intersected by narrow bush-clad valleys, and merging coastward into undulating plateaus, river valleys and shelving coasts. The streams are numerous but short. Practically the whole of the district is covered with forest. Large tracts can be prepared easily for pastoral purposes, but there is little ground suitable for agriculture. Gold is found in the valleys of the rivers, especially in those of the Arahura and Waiho, and gold-bearing quartz is also worked in some places. Silver, copper, iron and tin are among the other metallic treasures of the district, which has also yielded much coal, especially from the valley of the Grey. The climate is equable and temperate. The rainfall is heavy, and snow lies on the high mountains during much of the year. The capital is Hokitika, the other chief towns being Greymouth, Brunneron, Kumara and Ross. Railways connect Greymouth with Hokitika, Jackson and Reefton (in Nelson district). Westland was formerly part of Canterbury district. Pop. about 17,000.

**WESTMACOTT, west'mā-kōt, Richard,** English sculptor, son of Sir Richard Westmacott (q.v.): b. London, 1799; d. there, 19 April 1872. He studied under his father and also in Italy 1820-26, and after returning to England rose to prominence in his art. In 1857 he succeeded his father as professor of sculpture at the Royal Academy, having become associate member of the academy in 1838 and a full member in 1849. His style resembled that of his father in many respects. He published a 'Hand-

book of Sculpture' (1864) and a pamphlet 'On Coloring Statues.'

**WESTMACOTT, Sir Richard,** English sculptor: b. London, 1775; d. there, 1 Sept. 1856. He was the son of Richard Westmacott, also a sculptor, and was early trained to a knowledge of art by his father. In 1793 he was sent to Rome to study his profession under Canova, and there gained the annual gold medal for sculpture given by the Pope at the Academy Saint Luke. He also obtained a first prize for sculpture at Florence, and was elected a member of the Academy there. In 1798 he returned to England and rose rapidly in estimation as an artist. Many of the monuments in Saint Paul's Cathedral are by him, and that building forms, in some respects, a gallery of his works. The figure of a Welsh girl in a monument to the memory of Lord Penrhyn, at Penrhyn, in North Wales, is considered by many as his best creation. He designed also the statue of Nelson in Birmingham, besides figures of Addison, Pitt and many others. He became an associate of the Royal Academy in 1805, a full member in 1811 and in 1827 succeeded Flaxman as lecturer to the academy on sculpture. He was knighted in 1837.

**WESTMEATH,** Ireland, inland county of the province of Leinster, having Meath on the east, Roscommon on the west, Cavan on the north and King's County on the south; greatest length, east to west, about 40 miles; greatest breadth, north to south, about 35 miles; its area is 708 square miles, or 453,468 acres, of which 111,752 are under tillage. The surface is generally level, the land is chiefly in pasture Mullingar is the chief town, but Athlone is the great manufacturing centre. Pop. 59,812.

**WESTMINSTER,** London, England, a metropolitan and Parliamentary borough, formerly the ancient city and Liberty of Westminster, which still retains its civic title and certain privileges. Area, 2,502 acres. It is bounded on the south and east by the river Thames; east by the city of London, from which it was separated by the former Temple Bar; north by Holborn, Marylebone and Paddington, and west by Kensington and Chelsea. It is connected with Lambeth by Vauxhall, Lambeth, Westminster and Waterloo bridges. It has the highest valuation of any of the London boroughs (£6,821,491 in 1915), not excepting the City of London. The city contains some of the finest and most imposing buildings in London and teems with historical and literary associations. All the metropolitan royal palaces are within its limits and also Westminster Abbey, the Houses of Parliament, a fine modern Roman Catholic cathedral, the principal government buildings, the headquarters of the metropolitan police force, the National Gallery and the Tate Gallery, Burlington House, Somerset House and the principal theatres and opera-houses. It is divided into three Parliamentary constituencies, each returning one member, Saint George's, Hanover Square, the Abbey and Strand.

The History of Westminster goes back to a very early period. It became a city when, in 1540, Henry VIII made it the see of a bishop, and even though the see was suppressed 10 years later it retained the right to the style of city. The only (Anglican) bishop of Westmin-

as Thomas Thirlby. Since 1831 a branch Grosvenor family has borne the title of s, and since 1874 of Duke of Westmin- n 1850 a Roman Catholic archiepiscopal Westminster was created by Pope Pius e first occupant being Cardinal Wiseman. about 160,261. Consult Besant, 'West- r' (1895); Terry, 'Greater Westminster' ; Walcott, 'Westminster' (1849). See N.

**WESTMINSTER**, Md., city, county-seat of Carroll County, on the Western Maryland Railroad (Wabash System) about 35 miles west of Baltimore. The city is in an agricultural section, but it has considerable manufacturing interests. The chief industrial establishments are flour-mills, carriage factories, cigar and cigar factories. In the canning about 500 employees are engaged in the factories. There are nine churches. Educational institutions are the Western Maryland College (Methodist Protestant), founded in 1868; public and parish schools. There are three national and two savings banks. Government is vested in a mayor and council of five members, elected annually. The place was settled in 1724 by persons from the north of Ireland and a colony of English from Prince George County, of which at that time it was a part. Some Germans were also among the first settlers. The inhabitants are all American born, descendants of German, Irish, English, Dutch and French. Pop. 3,310.

**WESTMINSTER**, Order of the Holy Spirit. See ORDERS, RELIGIOUS.

**WESTMINSTER ABBEY**. See LONDON, Buildings.

**WESTMINSTER ASSEMBLY OF DIVINES**, a celebrated assembly held in the latter part of the 17th century for the settlement of a general creed and form of worship throughout Great Britain, at a time when Presbyterianism had gained a strong position in England as well as in Scotland. On the 23d of August 1641 the House of Commons (Long Parliament) addressed to the king a remonstrance desiring a synod of the most learned and pious men throughout the island for the reformation of the government of the Church; but this was not till 1643, after the civil war had that an ordinance was passed (on the 12th) convoking the long-proposed assembly of divines. By this act 121 clergymen, with 10 lay and 20 commoners as lay assessors, were appointed as constituents of the assembly. The assembly began its sittings on 1 July 1643 in the choir of St. Mary VII's Chapel, at Westminster Abbey, the meantime a proclamation forbidding the assembly to meet had been issued by the king, which had the effect of inducing the part of the Episcopal members to absent themselves, and Episcopacy was thus almost unrepresented. The majority of those who attended were Presbyterians, but there was a small and energetic minority of Independents. A deputation was now sent along with commissioners from the English Parliament to the general assembly of the Scottish Church at the Scottish Convention of Estates, soliciting their co-operation in the proceedings of the Westminster Assembly, and accordingly on

15 September four Scottish clergymen, Alexander Henderson, George Gillespie, Samuel Rutherford and Robert Baillie, with two laymen, Lord Maitland and Sir Archibald Johnston of Warriston, were admitted to seats and votes by an act of the English legislature. The assembly continued to hold its sittings till 22 Feb. 1649. Among the results of its deliberations were the 'Directory of Public Worship,' which was presented to Parliament on 20 April and ratified on 2 Oct. 1644; the 'Confession of Faith' presented to Parliament in October and November 1646 and ratified with a few verbal alterations in March 1648; the 'Shorter Catechism,' presented to the House of Commons on 5 Nov. 1647 and the 'Longer Catechism' on 15 Sept. 1648. In the latter period of the sittings of the assembly the growing power of the Independent party in Parliament presented a serious obstacle to the carrying into effect of its recommendations, though in 1648 an order of Parliament was pronounced declaring "all parishes and places whatsoever," with the exception of chapels for the king and peers, to be under the Presbyterian form of church government. The accession of Cromwell to power destroyed the hopes of the Presbyterians, and on the Restoration the whole proceedings of the Westminster Assembly, with the ratification of Parliament, were annulled as invalid.

While this celebrated convocation was thus allowed, as regards England, to remain almost inoperative, its deliberations have left on Scotland and on Presbyterianism as established in the United States, an impress which will never be effaced. The present standards of the Presbyterian churches are made up of the various formularies above enumerated. They were ratified by the Scottish General Assembly as follows: The 'Directory of Public Worship' in February 1645; the 'Confession of Faith' in August 1647, and the 'Longer and Shorter Catechism' in July 1648. Consult Hetherington's 'History of the Westminster Assembly' (1843; 6th ed. 1891); the 'Minutes of the Assembly,' edited by Mitchell and Struthers (1874); Mitchell's 'The Westminster Assembly' (1883); 'Cambridge Modern History' (Vol. 4, New York 1906), etc. See PRESBYTERIANISM.

**WESTMINSTER COLLEGE**, located at Fulton, Mo. It was founded in 1853 by the Missouri Synod of the Presbyterian Church. Though badly crippled during the Civil War by reduction in numbers and loss of endowment, the college continued its work throughout the war. In 1892 a bequest of nearly \$120,000 for permanent endowment was received and in 1897 the Alumni Association began a movement for further increase of this fund. In 1901 an amendment of the charter placed the college under the joint control of the Southern and the Northern synods of Missouri. The college formerly conferred the three degrees of A.B., B.L. and B.S. for the completion of the classical, literary and scientific courses respectively; but recently arranged its course in three groups corresponding to the former three courses, and confers the single degree of A.B. Each group includes required and elective studies. Bible study is required and Hebrew is among the electives. There is also an academy offering a classical and a literary and

scientific course and commercial courses. The campus comprises 18 acres on a wooded slope bordering on Stinson Creek. There are now four buildings, and productive funds totaling \$247,219. The library contains over 10,000 volumes; the students average annually 170 and faculty 16.

**WESTMINSTER COLLEGE**, located at New Wilmington, Pa. It was chartered in 1852, as Westminster Collegiate Institute under the auspices of the United Presbyterian Church. The board of trustees now consists of 40 members, the majority of whom are elected by two synods of that Church. The name was changed to Westminster College in 1892. The college offers two four year courses, leading to degrees, the classical and the scientific, and confers the degrees of A.B. and B.S. The work of the scientific course is mostly required; that of the classical course largely elective in the junior and senior years. Greek is required for the A.B. degree. There are also a three years' preparatory course, a department of music and an art department. Students maintain four literary societies. Any student taking more than one study of the classical course is required to belong to one of these societies. There is no general athletic association, but a football association, baseball association, etc. The college has a pleasant situation on elevated ground, some parts of the campus commanding a fine view. The buildings are the main building, scientific hall, the ladies' hall and the gymnasium. The productive funds in 1917 totaled \$498,201. The students average annually 250, the faculty 22.

**WESTMINSTER CONFESSION OF FAITH.** See CONFESSION OF FAITH, WESTMINSTER.

**WESTMINSTER HALL.** See LONDON, *Houses of Parliament.*

**WESTMINSTER PALACE**, London, England, an alternative name for the Houses of Parliament, perpetuated from the ancient palace built by Edward the Confessor as a royal residence and which contained the various national administrative and judicial offices. With the exception of the great hall, the building was destroyed by fire in 1834. The site is occupied by the new palace of Westminster or Houses of Parliament. See LONDON, *Houses of Parliament.*

**WESTMINSTER SCHOOL**, an ancient English public school established in Westminster Abbey by Henry VIII, and refounded in 1560 as Saint Peter's College by Queen Elizabeth. The school buildings closely adjoin the abbey, several of them having once been a part of the domestic buildings of the abbey, the great schoolroom being originally the monks' dormitory; others, such as Ashburnham House, belonging to the Post Reformation period. The institution was reorganized in 1868 as one of the seven principal public schools of England. The Westminster play, for which this school is noted, is a yearly performance by the pupils of some Latin comedy. Many eminent Englishmen have been educated at this school. Consult Forshall, 'Westminster School, Past and Present' (1884); Barker and Stenning, 'Westminster School Register' (1893).

**WESTMINSTER STANDARDS.** See PRESBYTERIANISM.

**WESTMOUNT**, Canada, city in Hochelaga County, province of Quebec. It is a residential suburb of the city of Quebec. Pop. 14,579.

**WESTON, Edward**, American electrician: b. London, England, 9 May 1850. He came to the United States in 1870 and engaged as chemist to a nickel-plating company. He devised various improvements in the process of nickel-plating and invented several dynamo-electric machines, establishing at Newark, N. J., in 1875, the first factory in America devoted exclusively to the manufacture of the latter class of machines. After the consolidation of his plant with another company in 1881 he continued as its electrician until 1888. He has since devoted his attention to the improvement of appliances for lighting by electricity and has introduced improvements in both arc and incandescent lighting. He was one of the founders of the American Institute of Electrical Engineers, of which he was president in 1888.

**WESTON, Edward Payson**, American pedestrian: b. Providence, R. I., 15 March 1839. In his youth he was a reporter on the *New York Herald* and was valued because of his ability to bring his night copy back to the office on foot quicker than could others traveling on the horse-cars of the period. He attracted attention in 1861 by walking 443 miles in 208 hours to attend the inauguration of Abraham Lincoln. His professional career began in 1867, when he walked 1,326 miles from Portland, Me., to Chicago, in 26 days. Later he engaged in six-day races, first in the effort to make 500 miles in a week, and when that record was passed he learned to run and created higher records. Some years later he again took to long walks on the highway, and in 1907 repeated his trip from Portland, Me., to Chicago, bettering the time 29 hours. Next he walked from New York to San Francisco, 3,895 miles (1909), in 104 days, 7 hours. The following year he walked back to New York, 3,500 miles, in less than 77 days. He has lectured on pedestrianism and temperance in numerous cities of the United States and England.

**WESTON, W. Va.**, town, county-seat of Lewis County, on the West Fork of the Monongahela River and on the West Virginia and Pittsburgh Railroad, about 78 miles south of Wheeling and 71 miles southeast of Parkersburg. It is in an agricultural region, in which considerable attention is given to stock-raising. It has a flour-mill, lumber and planing-mill and machine shop. A State hospital for the insane is located here. The two banks have a combined capital of \$150,000. Pop. about 2,780.

**WESTPHALIA**, west-fā'li-ā, or **WESTFALEN**, vēst'fā'lēn, Germany, a name originally given (1) to a large region of Germany; (2) to a duchy; (3) to an ancient imperial circle; (4) to a kingdom; (5) to a province of Prussia. These various divisions will be described in the above order.

1. The name of Westphalia was given from the second half of the 8th century to the western part of the ancient Duchy of Saxony incorporated by Charlemagne in the kingdom of the Franks, that is, to all the country between

the Weser and Rhine while the territory between the Elbe and Weser was called Eastphalia (Ostfalen). The latter name was lost after the dissolution of the Duchy of Saxony in 1180; the former was retained and was applied in the first place to a newly-erected duchy.

**2. Duchy of Westphalia.**—This was formed out of the part of the old Duchy of Saxony, then and still called Süderland or Sauerland, on the Upper Ruhr and Lenne. When Henry the Lion, the last of the old dukes of Saxony, was put under the ban of the empire, this territory was taken possession of by Philip of Heinsberg, archbishop of Cologne, who obtained the title of duke from Frederick Barbarossa. Cologne remained in possession of it until the dissolution of the archbishopric in 1801, upon which it was given, by way of indemnity, to Hesse-Darmstadt. In 1815 it was ceded by this power to Prussia and was united with the Prussian province of Westphalia.

**3. Circle of Westphalia,** one of the 10 circles into which the empire of Germany was divided by Maximilian I in 1512. It comprised the region between Lower Saxony, the Netherlands, Thuringia and Hesse, as well as considerable tracts on the left bank of the Rhine; but the proper Duchy of Westphalia, as an appendage of Cologne, was considered as belonging to the electoral circle of the Rhine. Its total area was 22,175 square miles.

**4. Kingdom of Westphalia.**—The Peace of Tilsit (July 1807) had made Napoleon master of all the Prussian territory west of the Elbe and he also kept possession of the territories of the electors of Hesse and Hanover and the Duke of Brunswick. Out of the countries just mentioned he created by decree of 18 Aug. 1807 a kingdom of Westphalia, with an area of 14,712 square miles and a population of nearly 2,000,000. Napoleon gave the kingdom to his youngest brother, Jerome, and on 15 Nov. 1807 a constitution similar to the French was granted to it. The insurrections that broke out in several parts in 1809 occasioned the adoption of various severe measures, and the introduction of an oppressive system of police. At the same time the king was required to bring his army up to a strength of 30,000 men, which produced great disorder in the finances. In 1810 a part of Hanover was added to the kingdom, the whole area of which was now 17,540 square miles. After the battle of Leipzig (1813) the kingdom was dissolved. On 26 October, Jerome was obliged to quit his capital (Cassel) and make his escape from the kingdom, whereupon the territories of which it was composed returned to their former possessors.

**5. The Prussian Province of Westphalia** was formed in 1815 out of some of the provinces which Prussia formerly possessed in the circle of Westphalia. It is bounded on the north by the province of Hanover; on the east by Hanover, Schaumburg-Lippe, Lippe-De-mold, Brunswick, Hesse-Nassau and the principality of Waldeck; south by the province of Hesse-Nassau, and west by the province of the Rhine and the kingdom of Holland. Its area is 7,800 square miles. The capital is Münster. The province in the south and northeast is generally mountainous, being traversed by the Westerwald, Rothhaar, Teutoburgerwald and the Wesergebirge. The northwest spreads out

into extensive and often marshy plains and belongs to the basin of the Ems; the northeast and a small part of the east to the basin of the Weser; the remainder, constituting the far larger portion of the whole, belongs to the basin of the Rhine. The soil is in general far from fertile. Livestock are numerous, particularly horned cattle, sheep and swine; the hams made from the latter have long been famous. The staple manufacture is linen, but that of iron is also very extensive. The region possesses the principal Prussian deposits of iron and coal and these were heavily drawn upon during the World War. Other minerals mined include copper, lead, zinc and salt. The province is divided into the three governments of Münster, Minden and Arnsberg. The population is about 4,250,000.

**WESTPHALIA, Peace of,** the treaty concluded in 1648 at Münster and Osnabrück, Westphalia (q.v.), which ended the Thirty Years' War and established a new political system in Europe. After preliminaries had been settled at Hamburg toward the end of 1641 the actual negotiations were begun in 1644, at Osnabrück, between the empire, Sweden and the Protestant states, at Münster between the empire, France and other foreign powers. Two treaties were drawn up, one at Osnabrück, signed 6 Aug. 1648, and one at Münster, signed 24 Oct. 1648. Peace was restored with the signing of the latter. By this peace the religious and political state of Germany was settled. The sovereignty of the members of the empire was acknowledged. They received the right of concluding treaties among themselves and with foreign powers, only not against the emperor and empire. Their consent was made necessary to enable the emperor to put any of the members under the ban. The concessions that had been made to the Protestants since the religious peace in 1555 were confirmed. The form of public worship and the right to secularize ecclesiastical benefices were to return to what they were at the beginning of the so-called normal year 1624. The Calvinists (Reformirten) received equal rights with the adherents of the Augsburg Confession or the Lutherans. The elector-palatine had the palatinate of the Rhine and the electorate restored to him; Alsace was ceded to France; Sweden received western Pomerania, Bremen, Verden, Wismar and a sum equal to \$3,750,000; Brandenburg, Mecklenburg, Hanover and Brunswick were compensated by the secularization of numerous ecclesiastical foundations. Germany lost altogether more than 40,000 square miles of territory and about 4,500,000 inhabitants. The independence of the United Provinces was recognized by Spain, and that of Switzerland by the empire. The solemn protest of Pope Innocent X against these terms, particularly in respect of the secularization of bishoprics and abbeys, etc., was not regarded; but the complete execution of the treaty was obstructed by many difficulties.

**WESTPORT, Conn.,** town in Fairfield County, on Long Island Sound at the mouth of the Saugatuck River, and on the New York, New Haven and Hartford Railroad, four miles east of Norwalk. It was established from portions of the towns of Weston, Fairfield and Norwalk. Westport contains three villages. It

is in an agricultural region and has a number of industrial establishments, chief of which are cotton-twine and button factories, machine shops and manufactories of satchels and morocco. It has a high school, elementary schools and a public library. There are two banks and a newspaper. Pop. about 4,259.

**WESTPORT**, Ireland, small seaport of the province of Connaught, county Mayo, at the mouth of a small stream that falls into Clew Bay, about 35 miles north-northwest of Galway. Formerly Westport was supported principally by linen manufactures; but is now known mostly for its trade in grain and provisions, and for its facilities for sea-bathing. In the immediate vicinity is the Reek Croagh Patrick, a mountain 2,510 feet high. Pop. about 4,000.

**WESTPORT**, Mass., town in Bristol County, on the Atlantic Ocean, seven miles south of Fall River. Its Horseneck Beach is one of the finest beaches on the coast. There are manufactures of cotton products. Pop. 2,928.

**WESTVILLE**, Ill., village in Vermilion County, 128 miles south of Chicago, on the Chicago and Eastern Illinois and the Cleveland, Cincinnati, Chicago and Saint Louis railroads. Its industries include coal mining and steel manufactures, and considerable corn is raised in the surrounding district. Pop. 2,607.

**WESTWARD HO**, one of the best known historical novels of Charles Kingsley, was begun in the spring of 1854 while Kingsley was living at Bideford and appeared the following year. The scene, laid chiefly in Bideford and at Plymouth and neighboring parts in the west of England, deals with the sea-faring English about the time of the Spanish Armada. The attempt is to picture the spirit of the English in their warfare against Spain. Historical characters, as Drake and Raleigh, are introduced, but the particular story is that of Amyas Leigh, his brother Frank and other members of the League of the "Rose of Torridge," so called from the beautiful heroine for whose hand these chivalrous and high-minded youths were rivals. Their individual rivalry was merged in the common cause against Spain, in which several, including Frank Leigh and the Rose, met their deaths. Finally Amyas, a stout-hearted young giant who had been particularly successful in vanquishing Spaniards, losing his eyesight, was obliged to pass the long remainder of his life in helplessness. The picture is a spirited one, though by no means in all respects historically accurate. The character and achievements of the English and the wiles and wickedness of the Spanish are painted with unstinting hands. As is usual in Kingsley's best-known works, like 'Alton Locke' and 'Hypatia,' even such chivalrous achievements do not constitute the best end of life. Only when Amyas Leigh, blind and helpless, can turn from an active to a spiritual life, is his highest happiness won.

WILLIAM T. BREWSTER.

**WESTWOOD**, John Obadiah, English entomologist and archaeologist: b. Sheffield, England, 22 Dec. 1805; d. Oxford, England, 2 Jan. 1893. He devoted himself to sciences, making extensive researches in the fields of entomology and archaeology; was one of the founders of the Entomological Society of London in

1833, and from 1883 its honorary life president. From 1861 until his death he was professor of invertebrate zoology at Oxford. His works on both entomology and English archaeology are numerous and important. Among the former are 'The Entomologists' Text-Book' (1838); 'Introduction to the Modern Classification of Insects' (1839-40); 'Arcana Entomologica' (1841-45); 'The Butterflies of Great Britain' (1855); 'Catalogue of Orthopterous Insects in the British Museum, Part I, Phasmida' (1859); 'Thesaurus Entomologicus Oxoniensis' (1874); 'Revisio Insectorum Familie Mantidorum' (1889), etc. His archaeological works, which are enriched by his excellent reproductions of manuscripts and illuminations and also by his drawings of inscribed stones and old ivories, are well known. Among them are 'Palaeographia Sacra Pictoria' (1843-45); 'Wood Carvings' (1864); 'The Utrecht Psalter' (1874); 'The Early Inscribed and Sculptured Stones of Wales' (1876-79); 'The Book of Kells: a Lecture' (1887), etc.

**WET BULB THERMOMETER**. See THERMOMETER.

**WETASKIWIN**, Canada, city and capital of Strathcona district, province of Alberta, 40 miles south of Edmonton and on the Canadian Pacific Railroad. It is situated in a rich agricultural district and is of growing importance as a manufacturing town. Pop. 2,411.

**WETHERALD**, Agnes Ethelwyn (Bri. THISTLEWAITE), Canadian poet: b. Rockwood, Ontario, 26 April 1857. She was educated at Pickering College, Ontario. For some time she edited the women's department of the *Toronto Daily Globe*, and she was subsequently connected with the staff of the *Ladies' Home Journal*. Her verse appeared in numerous magazines and she is author of 'The House of Trees' (1896); 'Tangled in Stars' (1902); 'The Radiant Road' (1904); 'The Last Robin' (1907), etc.

**WETHERELL**, weth'ér-él, Elizabeth. See WARNER, SUSAN.

**WETHERELL**, Emma (Abbott), American soprano opera-singer: b. Chicago, Ill., 9 Dec. 1849; d. 5 Jan. 1891. She first sang in public at the age of nine. Through the patronage and friendship of Clara Louise Kellogg she was enabled to go to New York 1870, where she was engaged in the choir of the church of the Divine Paternity, a number of whose members in 1872 contributed to send her abroad, and she studied for four years in Paris. She made her debut in London 1876 as Marguerite. For refusing to take the part of Violetta, in 'La Traviata,' on moral grounds, her engagement was canceled. In 1874 she was married to Eugene Wetherell. She made her first appearance in New York in 1877.

**WETHERSFIELD**, weth'érz-féld, Conn., town, Hartford County, on the Connecticut River and on the New York, New Haven and Hartford Railroad, three miles south of Hartford. In the summer it has regular steamer connections with New York and intermediate ports and it is connected with Hartford and other nearby places by electric railways. It has manufactories of mattresses, copying presses and agricultural implements. Important industries of the town are connected with the cultivation of seeds and the packing and shipping of

the same. It was one of the first places in the State settled by the colonists. It has a famous elm tree 26.6 feet in circumference. The First Church (Congregational) dates from 1761. A historic building is the Webb house, where, in 1781, Washington and Rochambeau met. A State prison is located here. The educational institutions are a high school, public and private schools and a public library. Pop. 3,500.

**WETMORE, Claude Hazeltine**, American author: b. Cuyahoga Falls, Ohio, 1862. He was educated at Western Reserve University, Cleveland, Ohio, and the École Polytechnique, Lausanne, Switzerland, and subsequently spent 10 years in South American travel. He has published 'Sweepers of the Sea' (1900); 'Fighting under the Southern Cross' (1901); 'In Inca-land' (1902); 'In a Brazilian Jungle' (1903).

**WETMORE, Edmund**, American lawyer: b. Utica, N. Y., 1838. He was graduated at Harvard University in 1860 and at the Columbia University Law School in 1863. He was thereafter engaged in law practice in New York and became one of the most prominent lawyers in the city. In 1900-01 he was president of the American Bar Association. The degree LL.D. was conferred upon him by Yale University in 1906.

**WETMORE, Elizabeth Bisland**, American author: b. Fairfax Plantations, La., 11 Feb. 1861. She was privately educated, and was for a time on the staff of the *New Orleans Times-Democrat*. She later established herself in New York, became one of the editors of the *Cosmopolitan Magazine* and was known as a magazine writer. She was married to C. W. Wetmore in 1891, and has lived much in England. Her work, published under her maiden name includes, 'A Flying Trip Around the World' (1891); 'A Candle of Understanding' (1903); 'At the Sign of the Hobby Horse' (1910); 'The Case of John Smith' (1916), etc. She edited 'Life and Letters of Lafcadio Hearn' (2 vols., 1906); 'Japanese Letters of Lafcadio Hearn' (1910).

**WETTER**, vêt'tër, Sweden, a lake about 24 miles southeast of Lake Wener, extending between the läns of Mariestad, Örebro, Linköping, and Jönköping; greatest length, 80 miles; medium breadth, about 15 miles; area, 715 square miles. Its height above the level of the Baltic is nearly 300 feet, but its depth is in some parts above 400 feet, or 120 feet below the Baltic level. Its water is very clear. It has periodic rises and falls independent of the wetness or dryness of the season and is subject, even in the calmest weather, to violent underground swells. When these take place in winter the sounds emitted by the ice in cracking and breaking up are often tremendous. An underground ridge is traceable throughout the whole length of the lake from north to south and its culminating points form the few islands which appear above its surface. The largest of these is the Visingsö, in the south. The Wetter forms part of a general line of navigation, which extends across the kingdom from east to west and far into the interior. By the Gotha Canal it communicates with Lake Wener, and by the Motala Canal with the Baltic. The scenery of the lake is in many places magnificent; the chief town on its shore is Jönköping.

**WETTERHORN**, vêt'tër-hörn ('peak of tempests'), Switzerland, one of the most striking peaks of the Bernese Oberland; has three summits—the west, called by the natives Hasli-Jungfrau, 12,147 feet high; the middle, known as the Mittelhorn, 12,165 feet; and the east, the Rosenhorn, 12,110 feet. These were ascended first in 1844 and frequently since, the ascent being made from Grindelwald. The contrast between the bright fresh pastures and the black precipices and dazzling snow ridges of the Wetterhorn is particularly striking, making the valley of the Reichenbach a favorite resort of artists.

**WEXFORD**, Ireland, maritime county of the province of Leinster, bounded north by the county of Wicklow, east by the English Channel, south by the Atlantic, west by the counties of Waterford, Kilkenny and Carlow; greatest length, north and south, about 60 miles; greatest breadth, east and west, 34 miles; area is about 901 square miles, or 576,588 acres. Pop. about 104,100.

**WEXFORD**, wëks'förd, Ireland, a seaport town, capital of the county of the same name, at the mouth of the River Slaney. The town is irregularly built and the streets narrow, but it contains some handsome buildings. It has a county courthouse, town hall, prison, theatre, barracks, etc.; three Roman Catholic churches, besides several Protestant places of worship, nunneries, a Roman Catholic college and various schools. Above the town there is a bridge across the river 1,500 feet in length. Wexford was a Danish settlement of great strength; it was captured by Cromwell in 1649; remains of its ancient walls exist. The harbor is spacious, but has a bar across the mouth. There is a dockyard and patent slip. The herring and salmon fisheries employ many persons; malt, agricultural implements and machinery are manufactured and distilling and brewing are carried on. The chief trade consists in the exportation of grain, cattle, poultry, butter, etc. In 1885 Wexford ceased to be a parliamentary borough. Pop. 11,154.

**WEYBURN**, Canada, town and capital of Assiniboia district, Saskatchewan, 300 miles southwest of Winnipeg, on the Canadian Pacific Railroad. The manufactures of the town are of growing importance. Pop. 2,210.

**WEYDEN**, vi'dën, Rogier van der, Flemish painter: b. Tournay, about 1400; d. Brussels, 16 June 1464. In 1426 he was apprenticed to learn painting, in 1432 became master in the painters' guild of Tournay, and in 1436 was chosen town artist of Brussels. His four works illustrating justice, executed for the "golden chamber" of the Hôtel de Ville, were destroyed by fire in 1695. In 1449 he journeyed to Italy, where he worked at Ferrara for Leonella d'Este, and painted also for the Medici and the Sforzas. He was the founder of the Brabant school. Among his principal extant works are a triptych in the Belvidere of Vienna; a triptych, 'The Last Judgment,' in the Beaune Hospital; and 'The Descent from the Cross' (Madrid gallery). Consult the study by Wauters (1856); and Crowe and Cavalcaselle, 'Early Flemish Painters' (3d ed., 1879).

**WEYER'S (wi'ërz) CAVE**, in Augusta County, Va., 11 miles northeast of Staunton.

It is a large stalactic cavern, in a spur of the Blue Ridge; and it contains a number of chambers, the largest of which is called Washington's Hall. This chamber is 250 feet long and nearly 100 feet high. This cave ranks next in importance to Mammoth and Wyandotte caves.

**WEYLER Y NICOLAU**, wā lēr é nē-kō-low, Valeriano, MARQUIS of TENERIFFE, Spanish general: b. Palma, Island of Majorca, 17 Dec. 1838. He was educated in Granada, entered the infantry school in 1853, and became under-lieutenant in the staff school in 1857. He was appointed lieutenant of the staff in 1860 and rose through higher ranks until in 1878 he became lieutenant-general. He was military attaché of the Spanish legation at Washington during the American Civil War and in 1868 was ordered to Cuba, where he served under Balmaceda through the 10 years' war. He was appointed governor-general of the Canaries in 1879, captain-general of the Philippines in 1889, and was afterward provincial governor of Catalonia. He succeeded Martínez Campos as captain-general of Cuba in 1896 and by the perpetration of many barbarities added to an already infamous record for cruelty in the conduct of the war then being waged on the island. His inhuman methods aroused the indignation of the people of the United States, where he became known as "Butcher Weyler," and in 1897, upon the change of cabinets in Spain, he was recalled. His reputation did not appear to suffer in his own country and in 1901-02 he was Minister of War in Sagasta's Cabinet and again received the post in 1905. When the rioting in Barcelona (1909) called for military interference, he took the field as captain-general and promptly restored a condition of order.

**WEYMAN**, wī'mān, Stanley John, English novelist: b. Ludlow, Shropshire, 7 Aug. 1855. He was educated at Shrewsbury School and Christ Church, Oxford, studied law, and was called to the bar in 1881. For nine years he practised on the Oxford circuit and then began a literary career in 1890 by publishing a romance entitled 'The House of the Wolf.' It was succeeded by 'The New Rector' (1891) and 'The Story of Francis Cludde' (1891), but it was his brilliant story, 'A Gentleman of France' (1893), that first brought him into prominence and on his historical novels his reputation rests. His later works include 'Under the Red Robe' (1894); 'My Lady Rotha' (1894); 'The Red Cockade' (1895); 'The Man in Black' (1896); 'Shrewsbury' (1897); 'The Castle Inn' (1899); 'Sophia' (1900); 'Count Hannibal' (1901); 'In Kings' Byways' (1905); 'Wild Geese' (1908). His tales are well constructed and written in a workmanlike manner, with plenty of incident and adventure, and the interest is well sustained.

**WEYMOUTH**, wā'mūth, England, seaport in Dorsetshire, on a beautiful semi-circular bay, seven miles south-southwest of Dorchester. The borough comprises Melcombe-Regis, from which it is separated by the small river Wey. It is well built; has two parish churches, one of them in Melcombe-Regis; several other places of worship, a general and an eye infirmary, town-hall, reading-room, Victoria jubilee hall, libraries, etc. There is a considerable coasting trade and an active traffic, passenger and other, with

the Channel Islands and France. There are ship-building, sail-making and rope-making establishments. Portland stone is exported from the neighboring isle of Portland (q.v.). Both Weymouth and Melcombe-Regis, particularly the latter, from the beauty of the bay and its smooth, firm sands, attract numerous visitors. There is a fine esplanade about one mile in length. Pop. about 23,000.

**WEYMOUTH**, Mass., town in Norfolk County, on Boston Harbor, and on the New York, New Haven and Hartford Railroad, 10 miles southeast of Boston. Electric lines connect the town with Boston and the nearby towns. Weymouth contains seven villages, each one having a post office. It has manufactories for boots and shoes, hammocks, fireworks and machinery. It has car-repair shops and extensive wool-scouring yards. The educational institutions are grammar and primary school; private schools; Tufts Library, which contains about 25,000 volumes; the Fogg Library, and a high school at Weymouth Centre. The town owns and operates the waterworks. The first permanent settlement was made in 1623 by Capt. Robert Georges, but the place had been visited often before this time, notably in 1622 by Thomas Weston. The place was first called by the Indian name Wessagusset, until it was incorporated 2 Sept. 1635, when the present name was adopted. Pop. (est.) 15,000. Consult Adams, 'Proceedings on the 250th Anniversary of the Permanent Settlement of Weymouth'

**WEYR**, vir, Rudolf, Austrian sculptor: b. Vienna, 22 March 1847. A pupil of Bauer and Cesar at the Vienna Academy, he won the Reichel prize with his 'Samson and Delilah' (1870) and in 1878 was commissioned to execute the decorations of the Grillparzer monument. His reliefs and experiments in polychrome sculpture won for him a considerable reputation. Besides numerous decorations for the university and museum buildings at Vienna, his works include the 'Triumphal Procession of Bacchus and Ariadne' for the pediment of the Burgtheatre, and the great fountain before the imperial palace.

**WHALE**. Any large cetacean is called a whale, while any small representative of the order is usually called a porpoise or dolphin. This division of the group is unscientific, however, and breaks down when the moderate-sized forms are in question, the layman being always in doubt whether these are to be classified as whales or as porpoises.

It happens that all cetaceans having whalebone, instead of teeth, or those constituting the suborder *Mystacoceti*, are of large or huge size. These may be all quite properly called whales, but it will be necessary for the present purpose to add to this natural group the sperm whale, a representative of the toothed whales, or suborder *Odontoceti* and the bottlenosed, or ziphioid, whales, which constitute the family *Ziphiidae*, and also belong among the toothed whales. The order then stands as follows:

Order Cetacea	Cetaceans
Suborder <i>Mystacoceti</i>	All cetaceans with whalebone
Family <i>Balaenidae</i>	(Co-extensive with the suborder.)
Suborder <i>Odontoceti</i>	All cetaceans with teeth.
Family <i>Physeteridae</i>	Sperm whales.
Family <i>Ziphiidae</i>	Bottlenosed whales.
Family <i>Delphinidae</i>	Porpoises or dolphins.
Family <i>Platanistidae</i>	River dolphins.

**Whalebone Whales.**—Whalers recognize several species of groups of whales with whalebone, to which they give the names of right whales, humpbacks, finbacks and sulphurbottoms. These correspond to natural groups or genera, except that the sulphurbottom is really a kind of finback. To these are to be added the California gray whale, or grayback, a very distinct genus, combining characters of right whales and finbacks, and the pygmy right whale of New Zealand. These various genera may be distinguished by the following external characters:

**Humpbacks (genus *Megaptera*).**—Form bulky and uncouth. Head broad and rounded in front, and flat on top, with rows of hemispherical tubercles. Belly with many broad longitudinal ridges and furrows. Pectoral fins very long (about one-third the length of the body), with serrations corresponding to the joints of the index finger. A low, thick dorsal fin. Flukes with a serrated margin. Color black and white. Whalebone short, dull blackish.

**Finbacks (genus *Balaenoptera*).**—Form slender and graceful. Head broad and flattish, more or less pointed in front. Belly with very numerous narrow ridges and furrows. Pectoral fins short, with plain margins. A falcate dorsal fin. Color gray and white. Whalebone short, striped gray and white, or entirely black, or black with white bristles, or entirely white.

**California Gray Whale (genus *Rhacianectes*).**—Form rather slender. Head comparatively narrow, moderately arched and pointed. No abdominal ridges or furrows, but two short furrows on the throat. No dorsal fin. Pectorals short. Color mottled gray. Whalebone short, white.

**Right Whales (genus *Balæna*).**—Form heavy and compact. Snout very narrow, and strongly arched. No ridges or furrows. No dorsal fin. Pectoral short and very broad. Color entirely black, or with a little white below. Whalebone very long, narrow, black.

**Pygmy Right Whale of New Zealand (genus *Neobalæna*).**—Similar to *Balæna*, but size small. A dorsal fin present. Whalebone white.

**Humpbacks.**—The humpback is in many respects the most remarkable of all whales. It reaches a length of about 50 feet. The anterior part of the body is very massive, but the posterior quite slender and at the same time so irregularly shaped and so awkwardly joined to the thorax that the animal appears misshapen. This effect is heightened by the dorsal fin, which is low and thick, with a concave anterior margin and rounded tip. Not less striking are the immense crenate-margined pectoral fins, like the wings of a bird, and about one-third as long as the body. The broad abdominal ridges nearest the median line join below on the throat, forming a chin-like protuberance. Humpbacks are infested by large barnacles of the genus *Coronula*, which fasten on the head, fins, flukes and abdominal ridges. Where they settle on the black skin but are afterward rubbed off, or otherwise got rid of, they leave behind distinct white marks, in the form of discs, circle, crescents, etc., which add to the singular appearance of these whales. Fastened to the large barnacles, are often

bunches of stalked barnacles, genus *Otion*, which hang down like fringes on the fins. Some 9 or 10 species of humpbacks have been described, but wherever observed they present characters so nearly alike that it is extremely probable that all belong to one widely-diffused species. The species of the Atlantic Coast of North America and Europe is *Megaptera nodosa*. Humpbacks occur in all seas, from the Arctic to the Antarctic. They congregate in bands, or schools, which sometimes number hundreds or even thousands of individuals. They are very irregular in their movements and indulge in all manner of uncouth actions. When they dive or sound they throw the flukes out of the water. Like other cetaceans they engage in seasonal migrations northward and southward. In the North Atlantic they withdraw from the waters of Greenland, Newfoundland, Iceland and Norway in fall and return in spring. They feed chiefly on fish.

**Sulphurbottom, or Blue Whale (*Balaenoptera musculus*).**—The sulphurbottom, as already stated, is a species of finback. Wherever finbacks are observed there are found to be four distinct forms. Each of these has been described from different localities under different names, but the variations are slight in each case, and have never been fully established, so that there is a strong probability that there are but four cosmopolitan species. These are the sulphurbottom, the common finback, the pollack whale and the little piked whale. Each form will now be considered separately, beginning with the sulphurbottom. The sulphurbottom is the largest of whales and the largest of all animals now existing, and was probably not surpassed in size by any animal living in earlier geological times. The largest individual of which there are authentic measurements was 88½ feet long. The average length for adults is about 76 feet. The sulphurbottom has a massive head and broad snout, and the body tapers gradually to the flukes. The dorsal fin is falcate and less than a foot long, and is situated at a point a little more than three-fourths the distance from the top of the snout to the notch of the flukes. The pectoral fins are falcate and about seven and one-half feet long, from the axilla. In color the sulphurbottom is gray, nearly uniform on the head, but mottled on the back and sides. On the belly are numerous white spots. The pectoral fins are gray above and white below, the flukes gray on both sides and the dorsal fin also gray, sometimes with a whitish centre. The abdominal ridges number 62 to 88. The whalebone is about three feet long, broad at the base and black in color, both plates and bristles. These huge whales feed exclusively on small crustaceans, the species in the North Atlantic being the thysanopod *Euphausia inermis*. The sulphurbottom congregates in the bays of southern Newfoundland, Iceland and northern Norway in early spring and remain until about July. Some individuals, however, appear to remain throughout the year, and their migrations are irregular and not well understood. They rarely strand on the east coast of the United States, nearly all the individuals reported as such belonging to the next species, the common finback.

**Common Finback (*Balaenoptera physalus*).**—This is the most commonly observed and best

known of the finbacks. In size it ranks next to the sulphurbottom. The form is exceedingly attenuated. Adult individuals reach an average length of 65 feet. The head is narrow anteriorly. The dorsal fin exceeds a foot in height and is situated as in the sulphurbottom. The pectoral fins are small, somewhat triangular, and about five feet long, from the axilla. This whale is gray on the back and upper surfaces of the pectoral fins and flukes and white on the belly and the under surfaces of the pectoral fins and flukes. The whalebone as a whole is gray, striped longitudinally with white, but at the anterior end of the jaw on the right side the whalebone is all white. The outside of the right lower jaw is also white. These parts are dark on the left side. This singular asymmetry of coloration is peculiar to, and characteristic of, the species. The common finback feeds on various kinds of small fish, especially the capelin, herring, young cod, etc.

In the North Atlantic it appears in spring in Massachusetts Bay, the Gulf of Maine, about Newfoundland, and in Greenland waters, as well as on the coasts of northern Europe. In the fall it withdraws from these waters and is supposed to migrate southward. The large whales which strand on the east coast of the United States are almost invariably of this species. When swimming or rising to spout, this whale, like the sulphurbottom, shows the top of the head and back and the dorsal fin, but nothing beyond. The flukes are not thrown out of the water when it dives or sounds.

**Pollack Whale, or Rudolphi's Rorqual** (*Balaenoptera borealis*).—This is a smaller whale than either of the preceding, adults reaching a length of about 45 feet. The form is more compact, the dorsal fin larger and more anteriorly placed. It is black on the back and sides, with a restricted gray or whitish area on the belly. The pectoral fins and flukes are dark gray, both above and below. The whalebone plates are black, but the bristles white. This whale, like the sulphurbottom, feeds on small crustaceans. Although large numbers of individuals were taken on the northern coast of Norway in some years when the fishery was at its height, it appears to be less abundant than the larger species. It was not positively known to occur on the east coast of North America until 1903, when four specimens were taken at the Newfoundland whaling stations. It cannot yet be considered more than a straggler in American waters. A similar, or identical, species has been observed in the Pacific Ocean, but little is known regarding it.

**Little Piked Whale, or Lesser Finner** (*Balaenoptera acuto-rostrata*).—This is the smallest of the finbacks and is not sought for by whalers. The form is thickset like that of a porpoise and the head pointed. When adult, it is about 25 feet long, and the maximum length is about 28 feet. The dorsal fin is larger than in any of the other finbacks and is situated farther forward, or at a point only about two-thirds the distance from the tip of the snout to the notch of the flukes. It is very dark gray or blackish on the back and sides and white on the belly, a little clouded with gray. The pectoral fins are blackish above, with a broad cross-band of white near the middle; below they are white. The flukes are blackish above and whitish below. In this species the abdominal ridges

are very numerous and narrow. The whalebone is very short and entirely white. The little piked whale feeds upon fish. It is found with the other species of finbacks in the North Atlantic, migrating northward and southward in the same manner, according to the season. A few specimens have been observed on the coast of New England, New York and New Jersey, either stranded or entangled in the nets of the fishermen. Whales of the same size and form and with the same peculiar markings have been observed on the coast of New Zealand, Argentina, Washington, Alaska and in other widely separated localities.

**California Gray Whale, Grayback or Devilfish** (*Rhachianectus glaucus*).—This remarkable whale is found only in the North Pacific. Its characters have been already enumerated above. When full-grown it has a length of about 40 feet. It is a restless and sagacious animal, and when wounded frequently attacks the boats sent out for its capture. In earlier days it was found abundantly in the winter months in the lagoons and bays of Lower California whither it repaired to breed. It is fond of playing in the surf and approaches close inshore to indulge in this recreation without fear of stranding. The gray whale is found as far northward as Bering Sea and occurs also on the coast of Japan, but has no counterpart in other seas.

**Greenland Right Whale, Arctic Right Whale, or Bowhead** (*Balæna mysticetus*).—In reviewing the observations of earlier zoologists, Cuvier came to the conclusion that but one species of right whale existed in the North Atlantic and Arctic oceans, an erroneous opinion, which nevertheless was accepted until the Danish cetologist, Eschricht, proved that the right whale of the Arctic was quite distinct from the species occurring farther south. This Arctic right whale, or bowhead, as it is called by American whalers, is most remarkable in appearance. The snout is narrow and arched like a bow. From the roof of the mouth depends the extraordinary, narrow black whalebone, which may be 12 feet long or even longer. This whalebone is enclosed and protected by the immense oblong lower lip, the curved upper edge of which fits against the side of the upper jaw when the mouth is shut. The back is without a fin, while the pectorals are short, and broad. There are no ridges or furrows on the belly. Adults reach a length of about 60 feet. The bowhead rarely or never leaves the Arctic ice, but like other whales it migrates northward and southward with the changes of the seasons. On the east coast of America it is never seen as far south as the southern extremity of Greenland, though there is a tradition that at the time of the discovery of the country it ranged as far south as the Strait of Belle Isle in winter. It occurs in the Arctic Ocean north of Alaska and ranges southward into Bering Sea. Individuals are believed to pass back and forth through the channels between the islands north of the continent from the eastern to the western side. The bowhead feeds chiefly on small pteropod mollusks and crustaceans which occur in vast multitudes in the Arctic Ocean. It is the most valuable of whales from a commercial point of view, on account of the thickness of the blubber and the length and fine quality of the whalebone, which

at present commands exceedingly high prices. its constant pursuit for three centuries has now very greatly diminished its abundance.

**Atlantic Right Whale, or Black Whale** (*Balæna glacialis*).—This whale resembles the bowhead in general appearance, but the head is smaller and less arched, and the whalebone shorter, or only about seven feet long. Near the end of the snout is a low rounded protuberance, called the "bonnet" by whalers. This bonnet is covered with barnacles, which are not found adhering to the bowhead. The black whale, as its name implies, is usually entirely black, but some individuals have been reported as whitish or grayish on the throat and breast. When full-grown it reaches a length of about 50 feet. Like the bowhead it feeds upon crustaceans and pteropod mollusks. The species has been nearly exterminated, but in former days it appeared regularly in the Bay of Biscay in winter and migrated northward to Iceland and northern Norway in spring. On the North American coast it ranges, or did range, as far south as Georgia in winter and toward the close of that season, or in early spring, appeared in Delaware Bay and off the coast of Long Island and Massachusetts, and later in the Gulf of Saint Lawrence. A few individuals still appear quite regularly off Long Island.

There is every reason to believe that this whale was the object of pursuit of the earliest whale fishers among the Basques in the Bay of Biscay in the Middle Ages. It was the species on which the American Colonial shore whale-fishery was based. So persistently was it pursued, however, that for many years it was supposed to be extinct and no remains which could be identified with it were to be found in any museum. Within the last 25 years, a few individuals have appeared every spring off the east coast of the United States, and a few have been captured, or have stranded, on the coasts of southern Europe and Iceland. As the right whale does not occur within the tropics, it has been questioned whether the large species observed about New Zealand, in the North Pacific and in other waters is the same as that of the North Atlantic. Opinion is at present divided on the subject, but it is generally conceded that the real differences between the right whales of the northern and southern temperate seas, if any, have yet to be pointed out. The Atlantic right whale, like the bowhead, feeds upon pteropod mollusks and crustaceans.

**Pygmy Right Whale of New Zealand** (*Neobalæna marginata*).—This is a remarkable little whale, resembling the large right whales, but reaching a length of only about 20 feet. It has a small dorsal fin, but no abdominal ridges or furrows. The whalebone is long and white. In color the whale is black, with a line of white along the belly. It has many osteological peculiarities, among which one of the most striking is the flatness and breadth of the ribs, of which there are 17 pairs. The lumbar vertebræ are only two in number. Little is known of the habits of this whale.

**Sperm Whale** (*Physeter macrocephalus*).—This whale, as already stated, belongs to the *Odontoceti*, or toothed whales, one of the two main divisions of the order Cetacea, which includes also the porpoises, river-dolphins and bottlenosed or beaked whales. But one species

of sperm whale is known. When full-grown the male reaches a length of 60 or 65 feet, but the female is much smaller. The head is of immense size, and is shaped like an elongated wedge with the base uppermost, and the edges and free end rounded. The blowhole is single and situated at the end of the snout on the left side. The lower jaw is very narrow and much shorter than the upper, and the two sides are joined together anteriorly for about one-half the length. In it are implanted about 44 large conical teeth which fit into pits in the upper jaw when the mouth is closed. There are no teeth in the upper jaw. The back is without a fin, but is raised into a number of low irregular humps posteriorly. The pectoral fins are broad and about six feet long. In color the sperm whale is blackish above and somewhat mottled with gray below. It occurs in all seas except the Arctic and Antarctic, but is essentially an animal of the tropics. The herds or schools are diversified in character, some comprising only young bulls; others, females and young led by an old bull, etc. At times old bulls are encountered wandering singly or in small groups. These old males are ill-tempered and pugnacious, and do not hesitate to attack the boats of the whalers. The sperm whale feeds upon large cuttlefish, which its great strength and powerful under-teeth are supposed to enable it to dislodge from their rocky retreats at the bottom of the sea.

**Bottlenosed Whales, or Beaked Whales** (family *Ziphiidae*).—This family comprises four or five genera of small whales, none of them exceeding about 30 feet in length. Several species of each genus have been described, but many of them appear to be without a certain foundation. Like the sperm whale, they belong to the suborder *Odontoceti*, or the toothed whales. They never have, however, more than four teeth regularly implanted in the jaws, but some species have numerous minute rudimentary teeth imbedded in the lips. The head of all the forms, at least in the young, is pointed, the dorsal fin low and placed far back toward the flukes, the pectoral fins narrow and of moderate length. In the bottlenosed whale of the North Atlantic (*Hyperoödon rostratum*) the forehead gradually increases in size with age, until it is sharply marked off from the narrow beak, like the shoulder of a bottle. The species congregates in large herds and is eagerly sought by whalers for its oil. The beaked whales of the remaining genera *Mesoplodon*, *Berardius*, and *Ziphius*, are far less abundant. They travel in pairs. *Hyperoödon* is peculiar to the North Atlantic, *Berardius* occurs only in Bering Sea and about New Zealand, while *Mesoplodon* and *Ziphius* appear to be cosmopolitan genera. The beaked whales subsist upon cuttlefish.

**Spermaceti**.—Spermaceti is the solid constituent of the crude oil of the sperm whale and some other cetaceans. The head of the sperm whale, between the skull and the integuments, is a kind of large reservoir of a semi-solid "head-matter" rich in spermaceti, but the substance is also contained in the oil of other parts of the body and especially the dorsal humps. To extract the spermaceti, the oil is boiled, chilled and afterward submitted to a very heavy pressure. The crude brown spermaceti is

refined by heating and bleaching with alkali. Spermaceti is a whitish, translucent substance, a little lighter than water, and soluble in chloroform, ether and carbon bisulphid. It melts at about 125° F. Though an excellent substance for candles, it has been very largely supplanted for that purpose by paraffin and other low-priced materials. The production in the United States in 1901 amounted to 400,000 pounds, valued at \$100,000.

**Whalebone.**—Whalebone is the outgrowth of horny substance from the epidermis of the upper jaw in whales of the family *Balanidae*. It takes the form of triangular plates, which differ greatly in size, proportions and color in different species. Plates to the number of 200 or 300 are attached by their bases transversely to the roof of the mouth on each side. They are longest in the middle of the series and at the ends become mere bundles of fibres. The plates are smooth and straight on the outer edge, but the inner edge is fringed with coarse bristles. The bristles of adjoining plates become matted together, forming a strainer by which the whale is enabled to retain in its mouth the fish or small crustaceans, etc., on which it feeds, while the water is squeezed out through the plates by the action of the tongue. In the right whales, the humpback and the sulphurbottom, the whalebone is black or blackish; in the common finback, striped gray and white; in the pollack whale, black with white bristles; and in the little piked whale, the California gray whale and the pygmy right whale of New Zealand, yellowish-white. The most valuable whalebone commercially is that of the right whales and especially that of the bowhead, which may have a length of from 10 to 12 or even 15 feet, and is very flexible. A single bowhead yields 2,000 pounds of whalebone, valued at from \$5 to \$7 a pound.

Whalebone from the humpback, sulphurbottom and finback is short, coarse and brittle, but also enters into commerce. Whalebone is used in the manufacture of corsets, in stiffening and adding gloss to certain kinds of cloth, for surgical instruments, whips, etc.

**Bibliography.**—For American whales consult Goode, 'Fishery Industries' (10th Census, Sec. 1, Washington 1884); Scammon, 'Marine Mammals' (San Francisco 1874); Bullen, 'Cruise of the Cachalot' (New York 1900). For cetaceans in general consult Beddard, 'Book of Whales' (London and New York 1900), which contains a copious list of references to other books. An exhaustive account of the whale fishery will be found in the 'Annual Report of the United States Fish Commission for 1883,' by Temple Brown.

F. W. TRUE,  
United States National Museum.

**WHALE-BIRD.** See FULMAR.

**WHALE-HEAD,** a stork. See BALANICEPS.

**WHALE-LOUSE,** any of various small crustaceans parasitic on whales. (See FISH-LICE). These crustaceans have a rudimentary abdomen, and have the limbs of the first joint of the thorax or chest inserted beneath the throat. The body is flattened and of oval shape and the legs are all prehensile. They burrow deeply into the skin of their hosts.

**WHALE OIL.** Oil obtained from a whale's blubber by trying out. (See WHALE). It is light yellow to dark brown. The variety known as sperm oil comes from the head of the sperm whale. The use of whale oil appears to be of ancient origin. It was doubtless first obtained from whales accidentally stranded on the shores, a more frequent occurrence during the early abundance of the cetaceans than at present, when their numbers have been so greatly reduced by excessive fisheries. As the demand for the oil increased beyond the supply available from stranded whales, individuals sighted from the shore were attacked and beached. Owing to the frailty of the boats and equipment, this was a more daring attempt than might be supposed. Just prior to the Revolutionary War there were 183 American vessels in the right-whale fishery of the North Atlantic waters and 125 were engaged in cruising for sperm whales from Newfoundland to the coast of Brazil. The Revolutionary War and the War of 1812 interfered with the fisheries; but during the period of peace following 1815 they increased greatly in extent until 1846, when the fleet numbered 678 ships and barks, 35 brigs and 22 schooners, a total of 735 vessels, with an aggregate tonnage of 233,189 tons and a value of \$21,075,000, exclusive of outfits and supplies. The entire capital invested in the fishery and its associated industries at that time approximated \$40,000,000 and 40,000 persons derived from it their chief support. During the same year the whaling fleet of all Europe numbered but 230 vessels. Large whales have been known to yield 250 barrels of 32 gallons, but probably an average for a large whale was 75 barrels and down to 12 barrels for a small bottle-nose whale. The crude value of the American catch from 1840 to 1860 averaged about \$8,000,000 annually. The greatest value was in 1854, when 2,315,924 gallons of sperm oil worth \$1.48½ per gallon, 10,074,866 gallons of whale oil worth 59½ cents per gallon and 3,445,200 pounds of whalebone worth 39½ cents per pound were secured, the total value being \$10,802,594. In the preceding year, 1853, the total product was 3,246,925 gallons of sperm oil, 8,193,591 gallons of whale oil and 5,652,300 pounds of whalebone, the whole valued at \$10,766,521. Sperm oil and whale oil then served nearly all the diversified uses for which oil was required, the chief exception being leather-dressing, for which neatfoot and cod oils were largely employed. The principal uses were as illuminant, lubricator, in cordage manufacture, screw-cutting and steel-tempering. The streets of the principal cities were lighted with the oil and theatres and public buildings were lighted with kag made from the oil settlings.

In 1902 the whaling fleet of the United States consisted of eight steamers, 18 barques and brigs and 12 schooners, aggregating 8,366 tons. Of these, 11 barques and 10 schooners were sperm-whale fishing in the Atlantic Ocean, eight steamers in the Arctic, six barques in Okhotsk Sea and off the coast of Japan, two schooners in Hudson Bay and one brig at Desolation Island. The total whale-oil product of the world in 1902 approximated 3,000,000 gallons, of which 750,000 gallons were produced by the United States fisheries, 900,000 by those of Norway and the

remainder by Scotland, Russia, Japan, Newfoundland, etc. Since that date the product has steadily reduced.

**WHALEBACK STEAMSHIP.** See STEAM VESSELS.

**WHALEBONE.** See WHALING.

**WHALING**, or the pursuit of whales as an industry, existed in the North Atlantic Ocean at a remote period. There are obscure references to it in Norwegian and English history as early as the beginning of the 10th century. In the 11th century the Basques pursued the North Atlantic right whale, or black whale (*Balæna glacialis*), with harpoons, in open boats. It is even asserted that they crossed the Atlantic in pursuit of their quarry before the time of Columbus, but this has not been substantiated. Certain it is that they visited Newfoundland immediately after the discovery of America and captured the same species of right whale in those waters. They are supposed also to have first seen the Arctic right whale, or bow-head (*Balæna mysticetus*), in the Strait of Belle Isle. In 1607 Henry Hudson encountered the bowhead in the vicinity of Spitzbergen. The Spitzbergen fishery developed rapidly on account of the large amount of oil yielded by this species and was extensively engaged in by various European nations, especially the Dutch, who in 1680 employed 260 vessels and about 14,000 men in the industry. During the decade beginning 1679, the Dutch took an average of about 1,000 whales annually. As the bowheads decreased about Spitzbergen, they were sought for to the westward, and in 1719 a Dutch vessel first entered Davis Strait. This fishery was developed chiefly by the British, Danes and Americans; in 1789 there were 255 British vessels engaged in it. The first American vessel visited Davis Strait in 1732. The number increased rapidly and at the height of the fishery, just before the Revolutionary War, Massachusetts alone sent 183 vessels to the strait.

About 1670, the American colonists succeeded in establishing a boat shore-fishery for the Atlantic right whale, which in those days was abundant on the coast, especially off Long Island and in Delaware Bay, and was well known from a much earlier date through stranded individuals. Later the colonists pursued the whales in sailing vessels farther from shore and in the Gulf of Saint Lawrence, but finally turned their attention to the Arctic right whale, or bowhead, in Davis Strait, as already mentioned.

About 1712 the first sperm whale was captured at sea by a Nantucket whaler. This fishery rapidly rose in importance and was pursued in all the oceans of the globe, especially by the Americans. The British did not apply themselves to it until 1775, but in 1790 a British whaling vessel rounded Cape Horn and opened up the Pacific fishery, which immediately grew to enormous proportions, and was at its height in 1837. The American whaling fleet in 1839 comprised 555 vessels, of which the majority were engaged in the Pacific sperm-whale fishery. In 1847 the number rose to 594, while the foreign whaling fleet numbered 230 vessels. The size of the American fleet reached its maximum in 1846, when 729 vessels were employed.

While a large part of the American fleet was engaged in the pursuit of the sperm whale, the remaining vessels were chiefly employed in hunting right whales, especially in the North Pacific. As the sperm-whale fishery declined, this branch increased in importance. In 1835 the famous Kadiak ground was discovered. A new epoch opened in 1843 when bowhead whales were first taken off the Kamchatka Coast. In 1848 the first vessel passed through Bering Strait to pursue these large whales in the Arctic Ocean. The fishery in the North Pacific and adjoining Arctic was at its height in 1852, when 278 vessels were employed. In 1866 the first American steam whaling-vessel was brought into use, and in 1880 two steamers were added to the Pacific-Arctic fleet.

The introduction of mineral oils for illuminating and other purposes and the decrease in the abundance of whales gradually broke down the fishery for right and sperm whales and at the present time the number of vessels engaged in the industry is negligible. A few sailing vessels still pursue the sperm whale, but in 1902 only five British vessels (steamers from Dundee, Scotland) entered Davis Strait in pursuit of the bowhead. The American whaling fleet in 1902 comprised 38 vessels, including eight steamers engaged in the Pacific-Arctic bowhead fishery. Of the remaining 30 sailing vessels, 21 engaged in sperm whaling in the Atlantic; six visited Okhotsk Sea and the coast of Japan, two entered Hudson Bay and one remained about Desolation Island. To-day (1918) there are so few that little record is kept of their activities.

The humpback whale was always pursued to some extent by right-whale whalers, but the finbacks and sulphurbottoms, besides furnishing a relatively small amount of oil, were too swift to be attacked successfully with hand-harpoons. About 1865, Svend Foyn, a Norwegian fisherman, invented a method of shooting them with a combined harpoon and bomb fired from a swivel gun mounted at the bow of a small steamer and for 30 years large numbers of sulphurbottoms, finbacks and humpbacks were killed annually at stations established on the coast of Finmark. Later the same method was employed at Iceland, The Farøe and Shetland Islands and also about Japan. In 1898 this mode of whaling was introduced into Newfoundland, where a number of sulphurbottoms, common finbacks and humpbacks are still killed annually.

A considerable number of common finbacks and humpbacks have been killed in Massachusetts Bay and the Gulf of Maine by means of explosive bombs attached to a special form of hand-harpoon, called a "darting gun." A boat-fishery of limited extent has been in existence for many years on the coast of California. It has for its object the capture of the California gray whale, and the humpback, which are killed by harpoons fired from a swivel gun mounted at the bow of a whale boat. Similar boat-fisheries exist on the coast of New Zealand, in the West Indies and in other parts of the world.

**WHALLEY**, hwō'fī, Edward, English regicide: b. England, about 1616; d. Hadley, Mass., about 1675. He was in trade, probably that of woolen-draper, at the outbreak of the

Civil War, when he enlisted for Parliament. In 1643 he became major in Cromwell's regiment of horse and in 1644 after having fought at Gainsborough and Marston Moor, appears as a lieutenant-colonel. He was made colonel of one of the two parts into which Cromwell's regiment was divided and with this force took Banbury and Worcester. Later, he was superseded. After Charles I was seized, Whalley was ordered to take charge of the king and in that post displayed much tact. He sat for Nottinghamshire in the two parliaments assembled by Cromwell, and in 1657 was made a member of the new House of Lords. He went to Scotland as agent of the army to mediate with General Monk, but had no success. On the Restoration he did not obey the summons of surrender of the king's judges and was therefore excluded from the indemnity. He sailed with William Goffe (q.v.) for New England, arrived at Boston 27 July 1660, resided for a time in Cambridge, but when the act of indemnity reached Boston in November and the town council met (February 1661) to consult regarding the refugees, went with Goffe to New Haven, where they arrived 7 March. He was associated with Goffe in the subsequent wanderings and concealments which have lent such interest to their history. Consult Stiles, 'History of Three of the Judges of Charles I' (1794); Noble, 'Lives of the Regicides' (1798); Hutchinson, 'History of Massachusetts' (3d ed. 1795); and the 'Collections' of the Massachusetts Historical Society, 3d ser. I 60, 4th ser. VIII 122. Mrs. H. M. Lothrop's romance 'The Judges' Cave' (1901) is founded on incidents in the New England career of Goffe and Whalley.

**WHARTON**, hwár'ton, Anne Hollingsworth, American author: b. Southampton Furnace, Pa., 15 Dec. 1845. She has written mainly though not entirely upon colonial themes and among her books are 'The Wharton Family' (1880); 'Through Colonial Doorways' (1893); 'Colonial Days and Dames' (1894); 'A Last Century Maid' (1895); 'Martha Washington: A Biography' (1897); 'Heirlooms in Miniature' (1897); 'Salons Colonial and Republican' (1900); and 'Social Life in the Early Republic' (1902); 'An English Honeymoon' (1908); 'In Chateau Land' (1911); 'English Ancestral Homes of Noted Americans' (1915).

**WHARTON**, Edith (Newbold Jones), American novelist: b. New York, 1862. She was privately educated and was married to Edward Wharton in 1885. She has since resided much abroad and has published 'The Greater Inclination' (1899); 'The Touchstone' (1900); 'Crucial Instances' (1901); 'The Valley of Decision' (1902); 'Sanctuary' (1903); 'The Descent of Man' (1904); and 'The House of Mirth' (1905); 'The Fruit of the Tree' (1907); 'Artemis to Actæon' (1909); 'Tales of Men and Ghosts' (1910); 'The Reef' (1912); 'The Custom of the Country' (1913); 'Fighting France' (1915); 'Summer' (1917). In return for services rendered during the World War Mrs. Wharton was made chevalier of the Legion of Honor of France. Consult Hawthorne, H., 'Women and Other

Women' (New York 1908); Underwood, 'Literature and Insurgency' (ib. 1914).

**WHARTON**, Francis, American lawyer: b. Philadelphia, Pa., 7 March 1820; d. D. C., 21 Feb. 1889. He was graduated in 1839, studied law, and was admitted to the bar in 1843. He was professor of logic and rhetoric in Kenyon College, Ohio, 1856-4 1863 took orders in the Episcopal Church became rector of Saint Paul's, Brooklyn. In 1866 he became a professor in the Divinity School at Cambridge, Mass., and held the chair of international law at the Boston Law School. In 1885 he was appointed counsel for the State Department at Washington and under a resolution of Congress was made editor of the Revolutionary correspondence of the United States. His best known work is a 'Treatise on the Criminal Law of the United States' (1846), accepted as a standard and has passed through many editions. Other works of his are 'Precedents of Indictments and Pleas'; a 'Treatise on Medical Jurisprudence'; 'Conflict of Laws' (1872); 'The Law Agency and Agents' (1876); 'Comments on the Law of Contracts' (1882); 'Treatise on the Law of Evidence and Criminal Issues.'

**WHARTON**, Philip, Duke of Edinburgh, politician: b. December 1698; d. Tarazona, Spain, 31 May 1731. At 16 he fled clandestinely and in 1716 traveled to the Continent and visited the Pretender at Aachen. That prince, gratified by his attentions, gave him the title of Duke of Northumberland. At the end of 1716 he returned to England whence he thence to Ireland, where he possessed a large estate, and was allowed, although not yet 18, to take his seat in the Irish House of Peers. He obtained a British dukedom in 1718 and on attaining his majority made his appearance in the English Parliament, where he distinguished himself as the defender of Bishop Atterbury, who was impeached as an adherent to the House of Stuart. He also published a virulent opposition paper called *The True Briton*. He entered the Spanish service and in 1727 was sent against the British at the siege of Calcutta for which he was in the following year tainted. His 'Life and Writings' appeared in 1732. Consult Robinson, 'Philip, Duke of Wharton' (1896).

**WHARTON**, Thomas, American journalist: b. Philadelphia, Pa., 1 Aug. 1859; d. 6 April 1896. He was graduated from the University of Pennsylvania in 1879, joined the editorial staff of the Philadelphia Times in 1881 and at the time of his death was Sunday editor of that journal. He published 'A Latter Day Saint' (1884); 'Hannibal of New York' (1886). His short story 'Bobbo' enjoyed great popularity and was republished, prefixed to a biographical sketch of the author by Wister as "Bobbo" and Other Stories (1897). It was dramatized and successfully played in England.

**WHARTON**, N. J. (formerly Philip Wharton), American lawyer: b. Philadelphia, Pa., 1830; d. 1890. He was graduated from the University of Pennsylvania in 1851, studied law, and was admitted to the bar in 1854. He was professor of logic and rhetoric in Kenyon College, Ohio, 1856-4 1863 took orders in the Episcopal Church became rector of Saint Paul's, Brooklyn. In 1866 he became a professor in the Divinity School at Cambridge, Mass., and held the chair of international law at the Boston Law School. In 1885 he was appointed counsel for the State Department at Washington and under a resolution of Congress was made editor of the Revolutionary correspondence of the United States. His best known work is a 'Treatise on the Criminal Law of the United States' (1846), accepted as a standard and has passed through many editions. Other works of his are 'Precedents of Indictments and Pleas'; a 'Treatise on Medical Jurisprudence'; 'Conflict of Laws' (1872); 'The Law Agency and Agents' (1876); 'Comments on the Law of Contracts' (1882); 'Treatise on the Law of Evidence and Criminal Issues.'

borough is situated in a coal-mining region, and there are blast furnaces. Manufactures include silks, paper and gunpowder. Pop. 2,983.

**WHARVES AND WHARF CONSTRUCTION.** The modern methods of wharf construction vary but little (except as to minor details) from the methods of the ancients. The process of constructing timber piers or wharves as practised in all of the ports of the Atlantic and Pacific seaboard is as follows: Piles of the best obtainable timber (generally pine or oak) are first driven to a solid foundation into the material forming the bottom of the harbor; these are designated as standard piles and are spaced from 6 to 10 feet from centres longitudinally and transversely (see Fig. 1), according to the desired carrying capacity of the wharf. These piles are then sawed off at the proper height above the tide level and on their tops (and fastened thereto with drift bolts) are placed timbers, often of yellow pine about 12 inches square. These timbers are known as the caps of the wharf. On these caps are placed the stringers or floor beams. They are generally four inches thick and vary from 12 to 16 inches in depth, according to the load to be sustained. They are commonly fastened to the caps of the wharf with spikes. The stringer system is placed about two feet out centres on this superstructure; the covering planks from three to six inches in thickness being fastened with the ordinary commercial spike of requisite length. After this portion of the wharf is finished nothing remains but to protect the same, either with a system of piles driven along the side used for mooring vessels (usually called fender piles and which are fastened to the superstructure of the wharf) and are sometimes additionally protected by wearing strips of timber and plank. (See Fig. 1.) A wharf projecting out from the

centre longitudinally and about five feet transversely; the outer pile in each bent is cut off one foot below the grade of the balance and is capped with a longitudinal sub-cap 12 inches square. The balance of the standard piles in each bent are cut off to conform with a crown of four inches in a 60-foot wharf and are capped transversely with 12 × 12-inch timbers. The piles after being stayed into position are mortised into caps having tenons seven and one-half inches wide longitudinally with the caps, three and one-half inches thick and three inches long; the caps are also drift bolted to each standard pile with a wrought-iron bolt one inch square. (In San Francisco, the caps are merely drift-bolted to each pile with a one-inch round iron drift bolt; no tenons are used). The stringer system, or as they call it there, rangers, are 12 × 12-inch timbers, spaced five feet apart, or so as to come directly over each standard pile, the outside stringers being composed of two pieces. The covering of the wharf is of two thicknesses of four inches each. In place of fender piles, the outside standard piles are utilized for fastening vertical fenders of 8 × 12-inch white oak timbers, extending from the sub-caps to the line of low water; there are also two lines of horizontal fenders of 8 × 12-inch oak extending the entire length of the wharf (with the exception of the four outer bents); one of these is fastened to the sub-caps and the other to the backing block; between these vertical fenders there are placed intermediate fenders of the same material but reaching merely between the two longitudinal fenders. In place of mooring piles there is used a cast-iron mooring bit. The four outer bents of the wharves are spaced about 20 feet from centre to centre. They consist of a double row of piles, each row containing the same number of piles as are

FIG. 1.—Cross Section through Ordinary Wharf.

water front line of the harbor is generally reinforced or braced by means of brace or batter piles driven on both sides of the wharf (see Fig. 1) at an angle of about 35 degrees with the perpendicular and they are fastened to the outside stringer as shown. The above describes more particularly the wharves as constructed on the Pacific Coast and in use in San Francisco since 1880. These wharves are 100 feet in width and about 600 feet in length.

**New York Wharves.**—In New York City, in wharves of the same area, contractors use about double the number of standard or bearing piles (with the exception of the four outer bents) as were used in those of San Francisco. The piles are driven 10 feet from centre to

under the regular caps, or making this row of double the carrying capacity of those caps. The end piles in each of these bents and the sheathing are so arranged that they present a rounded edge to the current. This is covered for a distance of four feet with an armature of boiler steel one-half inch in thickness and six feet in height, securely fastened to piles and sheathing. The wider spacing of the outer bent, the additional bracing and armature plates are for protection against floating ice. The timber for superstructure used there is what is known as hard yellow pine. The standard piles are generally of spruce and vary from 50 to 60 feet in length. The wharf timbers rarely exceed 30 feet in length.

**Boston Wharves.**—The ordinary wooden wharves of Boston are constructed as follows. Standard piles, generally of oak, are driven nine feet transversely and 10 feet longitudinally. They are bound together transversely on top with two girder caps of 6 × 10-inch hard pine and fastened to piles with one-inch screw bolts; the girder caps are let into the piles so that the same are spaced three inches apart. The outside stringers are of 10 × 12-inch and all inside stringers of 6 × 12-inch hard pine, spaced two feet from centre to centre. The wharves are covered with three-inch hard pine planks. The wharves are braced by brace piles called there spurshores; they are of oak and are shouldered against the outer standard pile at about one foot below mean high water and fastened thereto with one and one-fourth-inch screw bolts. In addition to bracing with piles, each bent has a set of crossbraces of 4 × 8-inch oak, running from a point about two feet above mean low water to the underside of the girder caps. These braces are fastened to each standard pile at each intersection with one-inch screw bolts; a horizontal tie of 4 × 8-inch oak is also placed one foot above mean low water and fastened to each pile with one-inch screw bolts. Fender piles of oak are driven in transverse lines with standard piles close up against the outer ones, and fastened thereto just below the girder cap with one and one-quarter-inch screw bolts. The fender piles are cut off nine inches below the top of the planking and are capped with 12 × 12-inch hard pine caps running longitudinally. These caps answer as longitudinal fenders and projecting three inches above the planking also as a curb or backing block. Mooring piles of oak are driven just inside of outer stringers and are held in place by four-inch planks fitted down into adjoining stringers and around mooring piles. The corners of these wharves are similarly piled and finished as are the wharves of Philadelphia and New York. A safe load for these wharves would be about 300 pounds to the square foot.

lants are five feet apart from centres versely and before being cut off at the level, they are straightened and stay in position. They are then bound together versely with girder plank of 6 × 12-inch, into piles, equally on each side, leaving a gap of four inches thick, 12 inches long a width being the full diameter of the pile are fastened to each pile with two screws. The cap proper is a single piece 8 × 16 laid on flat, covering the pile and at each edge with the girders; they are drifted to the piles and well spiked to the girder or clamps, as they are called. The wharves are braced in the following manner: At the mean low water two girders of 5 × 10 inch are fastened to each pile in each bent, one on each side of the pile; the spaces between the girders and the four outer piles on each side are braced with 12 × 12-inch timbers securely bound to the girder plank. The bents are then braced with "A" braces of 5 × 10 oak in four in number, dividing the bent into four panels, that is, a set of braces extend from the girder either way from the centre of the bent to a point at the under side of the deck distant from the outside of wharf one-third of its entire width. From the outside of the wharf at this same lower girder, another set of braces is run to the bottom deck, and, meeting the first set, they are bolted to each pile at the intersection with galvanized screw bolts. The stringer system is composed of a set of stringer of 12 × 14 inches and interspersed with 6 × 14 inches laid two feet six inches apart. They are gaged out at cap and level. The floor is composed of two layers of three-inch plank, dressed to a uniform thickness. The first is laid at right angles to the axis of the wharf, and the planks are placed six inches apart, these spaces over the stringers being filled solid for the full width. The planks of the outer section of this layer, about 12 feet length, are creosoted with 14 pounds of creosote oil to the cubic foot; they are fastened

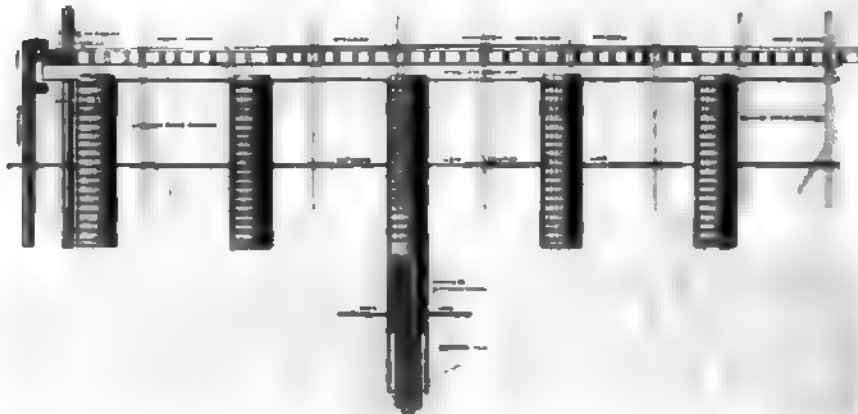

FIG. 2.—Cross Section through Wooden Cylinder Pier.

**Philadelphia Wharves.**—These wharves, with the exception of two outer bents, are constructed as follows. Standard piles are, as prescribed by the rules of the board of port wardens, driven in bents located longitudinally, 10 feet from centre to centre. The piles in these

stringers with wrought spikes one square and seven inches long. The plank or upper layer are laid close together at an angle of 45 degrees with the axis of the wharf and are spiked to the lower plank with wire nails averaging three feet apart.

WHARF CONSTRUCTION

Views of new Howard Street Wharf, San Francisco, Cal., showing the wooden cylinder pier system of construction

backing log or curb is a 10 × 12-inch oak timber, raised above the planking of the wharf and supported on blocking of 2 × 12 inches, laid five feet apart. Fender and brace piles are used only on the outer bents. The usual system of fenders is a series of 6 × 8-inch white oak timbers placed horizontally around the wharf between the top and the line of mean low water. They are placed about six inches apart and are fastened to vertical furring pieces of 8 × 12-inch yellow pine which are bolted to the front row of standard piles in each bent, these piles being surfaced off to receive them. The two outer bents are constructed as to spacing, protection, number of piles and braces as are the New York wharves. They have rounded corners, white oak fender piles, and in addition, fender piles at the ends of these two outer bents; they have also brace piles and corner bands and chocks connecting fender piles.

**Comparisons.**—Comparing the construction of eastern wharves with those of San Francisco, leaving aside those parts in the eastern wharves which are designed to resist the floating ice, the details of the construction of the San Francisco wharves are simpler; having no gains or tenons, they are not so apt to suffer from dry rot; and the fact of having but few joints in caps and stringers, they are, consequently, in this respect superior to the eastern structures. However, the construction of the San Francisco wharves is better, owing to the better materials for which the coast is famous. The length of timbers for wharf construction in the east very rarely exceeds 40 feet, but generally timbers up to 30 feet in length only are specified and used. In San Francisco wharves, timbers of from 60 to 100 feet and over in length are frequently employed and are to be had with only a very small additional cost. With piles it is the same, in eastern wharf construction; a pile 60 feet long is considered a very long pile, whereas on the Pacific Coast, piles from 100 to 130 feet in length can be had at any time. The life of the superstructure of the above-described wharves, especially if covered with sheds and buildings, is from 15 to 25 years, aside from the actual wear of the planking, but in sea water the life of an unprotected pile is from six months to three years owing to the ravages of the marine pests.

**Marine Pests.**—The most destructive of these are the *Teredo Navalis* or ship worm and the *Limnoria Terebrans*. The *teredo navalis* is worm-shaped, being from six inches to 14 inches in length and one-fourth of an inch in diameter. It is of gelatinous nature and translucent. Its head is provided with calcareous substance or shell in two parts working on a hinge which performs the office of an auger. The head, like the body, completely fills the cavity bored and the outward appearance of the pile attacked shows no indication of the destruction going on within. Having once entered the timber it never works out nor will one cross another hole although they are sometimes less than one-thirty-second of an inch apart, or from the surface. The teredo enters the timber at the ground level and works upward, generally about two feet above low water, although it will attack floating timber; the wooden floats or buckets of a ferry steamer making half-hour trips for 18 hours at a stretch and almost constantly in motion, have been

completely hollowed by the teredo. It was a theory at one time that the bark on a pile was a protection against the teredo. While this is true to a certain extent, piles taken from some of the old wharves in San Francisco Bay have been found badly eaten by these worms, the bark being otherwise intact. The *limnoria terebrans* resembles a wood louse in appearance. It is about the form and size of a grain of wheat; it works between high and low water and is very destructive. It completely destroys the pile between the tide lines avoiding all metal fastenings and knots in the wood. The borings are so close together that the wood is completely disintegrated; ends and joints of timbers seem to be the most favorable points of attack. The protection of piles and timbers from these marine pests has been the study of engineers and scientists for many years and millions have been expended on experiments with varying success. In the direct preservation of piles proper, two methods have been followed. The first and longest in use is impregnating it with chemicals that are destructive to animal life and the second is by covering the pile with an insoluble armor or artificial bark impervious to the worms.

**Cresoting.**—Without doubt the creosoting process is the most valuable and efficient of all processes known for prolonging the life of timber. The process was invented in England about the same time that kyanizing and the other metallic salt antiseptics came into use; it has survived all other processes and is used to a greater extent than any other method both in Europe and this country. The creosote is derived from the destructive distillation of wood and coal and consists of oil products designated as dead oil when derived from the distillation of coal or coal tar and wood creosote oil when derived from the distillation of wood or wood tar. The dead oil contains naphthaline, phenic or carbolic acid and other powerful antiseptics which change the chemical nature of the sap by forming therewith soluble compounds while the naphthaline rendered sufficiently fluid by preliminary heating, enters the wood cells, solidifies and becomes permanently fixed, mechanically coating and protecting the fibres against formation of fungi. The wood creosote contains paraffine, pyroligneous acid and other antiseptics. The advantages claimed for this oil are that its penetrating power is much greater and it is less expensive than dead oil and is equally soluble in water. The limited use of this oil seems to confirm these claimed advantages, but the matter cannot be considered conclusive until more definitely established by further experience and the test of time. All experts on preservation of timber agree that the density of timber must be favorable to impregnation; in other words, only open-pored timbers should be used for treatment with creosote, this having the least liquidity and, therefore, the hardest of all preservative chemicals to force into and thoroughly impregnate the wood. The Oregon pine or yellow fir used on the Pacific Coast is considered too dense to permit a thorough impregnation and if treated with creosote requires a longer steaming and a greater heat to extract the sap and open the pores and also a greater pressure to force the material into the wood. The consequences therefrom have been checking and cracking the timber, making it brittle

and when used for piles the process has cracked them so extensively that the limnoria were found in and behind these cracks in sheltered places in which it has done its destructive work under cover and more rapidly than when exposed to swell and current. It has also made examination of those piles more difficult, as the outer shell of the pile was apparently unattacked while the inner portion of the same was entered and destroyed by the limnoria. All authorities in writing on the preservation of piles for marine work seem to ignore the existence of the *limnoria terebrans*. In my opinion it is much more destructive on the Pacific Coast than is the teredo, and while a pile that has been thoroughly creosoted will resist the

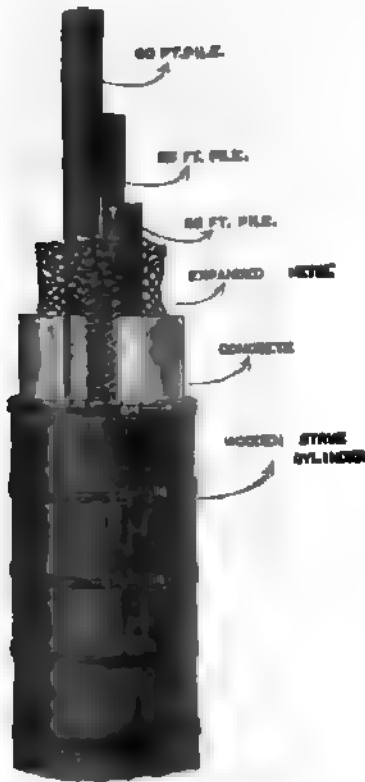

FIG. 3.—Detail of Wooden Cylinder

teredo, even if somewhat checked, the limnoria will find the slightest opening and destroy the pile. There have been several methods for the preservation of piles in San Francisco Harbor by means of an exterior covering or artificial bark, some of which have been more or less successful, the success depending upon the durability of the covering, or, in other words, the life of the pile is the life of the artificial bark. The one making the best showing, from the fact that it has been the longest in use, is the paraffine method. It consists of a surface of paraffine paint, covered with hattens which have been treated with the paint. The secret of the success of this process is the fact that it is applied cold. Previous coverings of this character having been applied hot to a wet pile, no adhesion was obtained between covering and the pile for the reason that the hot material

draws the moisture to the surface. This difficulty claims to have been avoided by the parties kiln-drying the piles before covering. This process consists in covering the piles spirally with a double thickness of burlap treated with asphalt, the application or winding of the burlap being done by means of a large lathe in which the piles are turned. Another protection against these marine pests is a pile built up from a core of 6×6 with one-inch boards until it is 12 inches square, each layer being tarred and sanded. It is built on the theory that the teredo is loath to cross a seam and the test pile taken from section I of the seawall, a particular feeding ground of the teredo, after 10 years' immersion, verified this theory. But this was a case of again ignoring the ever active limnoria, and piles built since have shown that the limnoria found a home in the seams of the boards of which the pile was constructed. An improvement was made in the details of construction which has resulted in keeping the limnoria out and that was the placing of ship felt between the last two layers of boards from high water to two feet below low water (limnoria working only between high and low water). In many of the government piers where the teredo and limnoria are particularly active, numerous iron piles have been used, both wrought and cast. These are prohibitory in many places by reason of excessive cost of the material and construction, most of the piles having either to be screwed into the bottom or driven with a water jet. Another objection is the rapid destruction by oxidization of the joints in the bracing system.

**Cylinder Construction.**—A mode of construction which has been very successful on the Pacific Coast was invented by the writer and has been in use in the San Francisco Harbor for many years. It is the wooden cylinder pier construction (See Fig. 2). The foundation proper consists of cylinders of concrete and piles placed about 15 feet on centres. The details of construction are as follows: The core consists of one or more piles, generally three; these are driven to a firm foundation and are left at different heights from the finished top of the proposed wharf, for example, say one pile is 50 feet in length, one 55 feet and one 60; this is for two reasons: first, for economy, as in the San Francisco Bay most of the piles depend absolutely on the friction of the mud for sustaining purposes (there being no known bottom) and it will readily be seen that the 50-foot piles will be as deep in the mud as the 60; secondly, it admits of a larger body of concrete at the top of the cylinder where required. After this cluster of piles is driven, there is then driven over and encircling same a wooden stave cylinder, generally four feet inside diameter; these staves are from three to four inches thick and bound together with wrought-iron hoops having adjustable lugs; these hoops are placed about two feet on centres and the cylinder is made perfectly water-tight. It is driven with an ordinary pile-driving machine from 10 to 15 feet into the mud. The water and mud in the interior is then pumped out to a depth of from two feet to five feet below the mud on the outside; then inside of this cylinder of wood, between it and the piles, is placed an interior cylinder of expanded metal or similar metallic

interstitial web about one foot less in diameter than the interior of the wooden cylinder. The interior is then filled with a rich concrete of hydraulic cement and broken rock. The cylinder pier is complete and forms a teredo-proof concrete pier, having a wooden core reinforced with an interstitial web of expanded metal and protected for at least four years with an iron bound wooden jacket. (See Fig. 3). These cylinders are then capped with caps of structural steel, generally two 15-inch I-beams and the balance of the superstructure is as in the ordinary wharf. The fender system is somewhat different from that in general use and is as follows: The fender piles are driven in pairs about 10 feet apart and about one foot away from the wharf proper; they are connected together longitudinally with a ribbing composed of three timbers both at the surface and below the top of wharf. (See Fig. 4). Be-

FIG. 4.—Side Elevation.

tween these fender piles and the outside stringer are placed a nest of heavy spiral springs similar to those used on a buffer in a freight car. This is the only direct connection between the wharf proper and the fenders; the upper ribbing at the surface of the wharf acts in the dual capacity of a curb for the wharf and a support for the fender line. This spring fender line saves the jar to both vessel and wharf and in ordinary choppy weather there is not the slightest motion to the wharf; it also saves the wear on the fender piles as these last but from one to two years, due to wear and breakage. For example, in pier No. 12, San Francisco, used by the United States transport steamers, the fender piles with the spring system have been in use seven years without a single renewal, while at pier No. 4, used by steamers of half the tonnage, all the fenders have been renewed twice in that period of time. The cylinder pier system construction has been used by the Santa Fé System, the North Shore Railroad Company and the San Francisco, Oakland and San José Railroad Company and is to be used by the Pacific Mail Steamship Company in the construction of four new piers. See HARBORS, DOCKS AND BREAKWATERS; PIER

**WHAT CHEER**, Iowa, city in Keokuk County, on Coal Creek and on the Chicago and North Western and the Chicago, Rock Island and Pacific railroads, about 70 miles southeast of Des Moines. It is in an agricultural and coal mining region, and has several industries connected with farm and dairy products. It has six churches. The two banks have a combined capital of \$80,000. Pop. 1,805.

**WHAT-CHEER**, in Rhode Island, a watchword or shibboleth, derived from the fact that the Indians of the colony thus greeted Roger Williams and his companions, when they first landed on the Sekonk River near the present site of Providence.

**WHATCOM**, hwöt'kóm, Wash., city, former county-seat of Whatcom County. See BELLINGHAM.

**WHATELY**, hwát'fl, Richard, English prelate, archbishop of Dublin: b. London, 1 Feb. 1787; d. Dublin, 8 Oct. 1863. He was educated at Oriel College, Oxford, and in 1819 made his first appearance as an author by publishing his since famous 'Historic Doubts relative to Napoleon Bonaparte.' This pamphlet is among the most popular of the author's writings, more than 12 editions of it having been published. Its object is to show that objections of the

same kind as those brought forward by skeptical writers of the truth of the gospel narratives, founded on apparent inconsistencies and absurdities in these narratives, may be brought against any well-known and incontrovertible piece of history, such as that of Napoleon Bonaparte. In 1822 Whately delivered the Bampton lectures at Oxford, 'On the Use and Abuse of Party Feeling in Matters of Religion.' The same year he received the living of Halesworth in Suffolk, and was appointed principal of Saint Alban's Hall, Oxford, in 1825. In 1825 was published perhaps the most widely known of his works, 'The Elements of Logic,' and the scarcely less popular 'Elements of Rhetoric' in 1828. Whately was appointed professor of political economy in 1830. The lectures he then delivered were afterward published under the title of 'Introductory Lectures on Political Economy.' In Oxford, Whately stood in the front rank of those who held liberal views in ecclesiastical and social matters and among these his earnest love of truth, his contempt for arguments resting solely on tradition and the keenness of his logic gave him great influence. In 1831 he was appointed archbishop of Dublin and bishop of Glendalough. The cause of national education in Ireland he warmly embraced and for 20 years was an active and influential member of the board. Consult 'Life and Correspondence of R. Whately, D.D.' by his daughter, E. J. Whately (1866).

**WHEAT**. Wheat belongs to the Hordeæ tribe of the Gramineæ or grass family. There are four principal kinds of sub-races: common wheat (*Triticum sativum vulgare*), Egyptian

and English wheat (*Triticum sativum turgidum*), flint wheat (*Triticum sativum durum*), to which the durum and macaroni varieties belong, and a dwarf variety (*Triticum sativum compactum*), supposed to have been the kind produced in ancient times. Each sub-race is in turn divided into many varieties. The wheat most generally cultivated and in most common use for bread purposes is *Triticum sativum vulgare*, although varieties of durum and spelt are extensively grown in some localities.

Wheat is of ancient origin and was cultivated by prehistoric races, as the Swiss Lake-Dwellers. In the earliest writings it is mentioned and samples which are not materially different from similar modern varieties have been found in a fair state of preservation in ancient tombs. Attempts have been made to germinate this "mummy wheat," but without success. The Chinese claim that wheat was used by them as food 2,700 years before the Christian era and in Egypt its use as food appears even to antedate this period. A number of varieties have been cultivated from early times, as spelt, durum, and winter and spring varieties of *Triticum sativum vulgare*. Wheats produced in different countries have been subject to different climatic and soil conditions as well as to different methods of cultivation until material changes have taken place and numerous hard and soft varieties have been produced. There appears to be no authentic record of wheat growing wild and sowing itself without the help of man.

The world's wheat crop normally amounts to about 3,750,000,000 bushels, of which the European countries produce a little more than half. At present the United States is the greatest wheat-growing country—about 850,000,000 bushels are produced annually. In 1915 the yield was about 1,000,000,000 bushels. There are large wheat areas in the northwestern possessions of British North America which have not yet been brought under full cultivation. There also are large undeveloped wheat regions in South America, particularly in the Argentine Republic, and it is claimed that some undeveloped parts of Siberia are suitable for wheat production. Thus it is evident that there are vast areas of fertile virgin soil yet to be brought under wheat cultivation.

Wheat can be grown on a variety of soils. It thrives best, however, and produces largest yields upon rich alluvium, and soils formed from different kinds of rock thoroughly disintegrated and mixed with vegetable mold. The wheat soils of the northwestern wheat region of the United States are largely of glacial formation and composed of clay and silt with small amounts of fine sand and containing liberal amounts of alkaline matter, particularly disintegrated limestone. The best wheat soils are rich in humus (decaying vegetable matter), which through decay supplies nitrogen, one of the principal elements used by the wheat plant for the formation of gluten.

The tendency in wheat farming upon new soils has been to grow the crop for a number of years without practising rotation or using fertilizers. After a time this results in reduced yields and an inferior crop, due in part to the loss of nitrogen from the land. Wheat does

not remove a large amount of gross fertility from the soil, but exclusive wheat culture on virgin soil causes a rapid decay of the humus and a consequent loss of nitrogen, one of the elements of which humus is composed. When wheat is grown along with other farm crops in a good rotation and manures are intelligently used the wheat does not have an exhausting effect upon the soil. The chemical composition of a wheat soil of high productivity from the Red River Valley of the North is as follows:

	Surface per cent	Sub s. f. per cent
Insoluble matter	47.64	41.21
Soluble silica	15.43	8.17
Potash	0.54	0.25
Soda	0.45	0.48
Lime	2.44	7.45
Magnesia	1.85	4.48
Iron oxide	4.18	3.48
Alumina	7.89	10.72
Phosphoric anhydrid	0.38	0.17
Sulphuric anhydrid	0.11	0.10
Carbonic anhydrid	2.42	14.26
Volatile matter	15.55	6.22
Humus and volatile matter	5.34	0.89
Nitrogen in volatile matter	0.38	0.11

The yield of wheat ranges from 10 bushels and less to 30 bushels and more per acre. In countries where land is expensive, and intensified farming is practised, the yield per acre is generally larger than in new regions where more land is available. The yield per acre of wheat in the United States is much less than the soils are capable of producing.

Formerly plowing was done with a bent stick or wooden plow, the wheat was sown broadcast by hand, the crop was cut with the cradle and bound in sheaves by hand, and finally thrashed with the flail or by the trampling of horses. Improvements in machinery, as steam and gang plows, seeders, reapers, self-binders and threshers, have greatly reduced the cost of production and increased the world's supply of wheat. Equally as great have been the advances in transportation, storage and milling facilities. Wheat is now transported in specially constructed freight cars and boats, and stored in large elevators in which 120,000 bushels are placed in one compartment, when formerly it was often transported on horse or mule back in bags, loaded and unloaded by hand and stored in small bins and granaries. The milling process has developed from crushing between two stones to reduction by steel rolls.

Wheat is subject to a number of diseases, as rusts, smut and other vegetable parasitic diseases, many of which have been studied and are now in part capable of being controlled. The smuts are destroyed by treating the seed wheat with chemicals which kill the smut spores, while the rusts are held in check by destroying the host plants, as the barberry, upon which the parasite spends part of its cycle of life. There are a number of insect pests which often cause great destruction of the crop, as grasshoppers, frit flies, Hessian flies and chinch bugs. Economic entomologists have done much to save the wheat crop from insect ravages.

The wheat kernel is surrounded by a seed pod composed of cellulose which constitutes the outer layer and is called the pericarp. The second covering or episperm, which is just within the pericarp, consists of the outer and inner integuments. The perisperm or third bran layer is a thin mass of collapsed cells. The aleurone layer—so-called gluten cells—is composed mainly of nitrogenous matter and lies within the three-bran layers. The endosperm of floury portion constitutes about 80 per cent of the wheat kernel and is within the three-bran layers and aleurone cells. The germ or embryo plant is stored in the lower part of the kernel where its outline can be traced by the indentations, the germ makes up about 6 per cent of the offal of the kernel, or about  $1\frac{1}{2}$  per cent of the entire kernel, the bran layers about 12. The relation of the different parts, one to the other, as bran to endosperm, varies in different kinds and varieties of wheat, some producing a larger amount of flour than others and some more bran.

The character of the wheat, as starchy or glutinous, is determined largely by soil and climate. A short, forcing growing season and a fertile soil have a tendency to produce glutinous wheat, while the opposite conditions produce starchy wheat. When hard glutinous seed wheat is sown in regions which produce starchy soft wheats, the hard wheat gradually changes its character and in about two years becomes starchy. Whether a wheat is hard or soft depends upon the amount and character of its gluten. Hard wheats usually contain over 12 per cent gluten, of which 45 to 65 per cent is in the form of gliadin, an alcohol soluble protein, while soft wheats contain less gluten, but gluten of a higher gliadin content.

Extensive experiments have been performed by Lawes and Gilbert of Rothamsted, England, to determine the influence which different kinds of fertilizers have upon the wheat crop. They have shown that fertilizers influence the yield more than the percentage composition of wheats and that it is not possible by means of fertilizers alone to increase materially the amount of starch or gluten. Climatic conditions affect the command that it is not possible by means of fertilizers. Wheats grown upon the same soil in different years show greater variations in composition than wheats grown the same year but differently fertilized.

Different varieties of wheat when grown under the same conditions are fairly constant in composition. In protein content, wheats range from 7 to 18 per cent. The most nitrogenous wheats do not necessarily make the most glutenous flours, as frequently a large portion of the nitrogen is in the germ and offals.

The grading of wheat is based entirely upon the physical qualities as weight per bushel, color and plumpness. Smut and blemishes, caused by unfavorable climatic conditions, are also considered in grading wheat. When new wheat is stored in elevators, a slight fermentation change takes place known as "sweating." If the wheat is sound this change is slightly beneficial for flour production, as it improves the qualities of the flour. Unsound wheats, as those which are bleached, frosted, immature and sprouted, usually have a somewhat different composition from fully matured wheat. Such wheats may contain a larger amount of soluble

proteids, soluble carbohydrates, and organic acids than normal wheats. Damaged wheats generally yield a smaller amount of flour as well as flour of poor keeping qualities.

It is not possible to make accurate comparisons as to composition of wheats grown in different countries. It will frequently be found that wheats grown in different localities of the same country vary as much in composition as do wheats grown in different countries.

Wheat contains slightly more protein and less starch than corn, oats, rye or barley. Oats from which the hulls have been removed contain more protein and fat than wheat. The difference in composition between wheat and the other cereals is not large and occasionally individual samples of corn or rye will be found containing more protein than individual samples of wheat. Wheat differs in composition from all other cereals in that its gluten is composed of the two proteids, gliadin and glutenin. This gives flour its bread-making value. It has also been found that the wheat proteins contain both different kinds and amounts of amino acids from the proteins of other curds. No other cereal except rye contains a gluten that is capable of expanding and forming a light porous loaf. Because of its unique composition no other cereal can take the place of wheat for bread-making purposes.

Numerous experiments have been made to improve the quality of wheat by selection of seed, and by breeding and crossing of standard varieties. Wheat responds readily to such tests, but unless great care is taken it as readily reverts to its original condition. In the United States two main classes of wheat are produced, namely: winter and spring wheat, of which there are a number of varieties, as white and red winter wheat, "Turkey Red," Oregon Club, Blue Stem, Scotch Fife, Marquis, etc. Minnesota, North and South Dakota, and Montana constitute the main spring wheat region; spring wheat is, however, grown in other localities.

The wheat plant assimilates its mineral food and nitrogen from the soil at a rapid rate. In the case of spring wheat, by the time the crop is half grown, over three-fourths of the mineral food and nitrogen needed for construction purposes have been taken from the soil. Wheat is not a strong feeding plant and taking its food from the soil in so comparatively short a time, the soil must be in a high state of productiveness in order to yield a good crop. The wheat plant needs greatest assistance in securing its nitrogen, hence fertilizers for wheat should be nitrogenous in character. Wheat also needs a good supply of available mineral food as phosphoric acid and potash, but is better able to secure these elements from the soil than it is nitrogen.

The flour yield of wheat is determined approximately from the size and weight of the kernels. Light weight wheat has a low flour content.

Because of its usually high price, wheat has never been extensively used as animal food, but at times when it has been cheap and abundant, it has been used for the feeding of all farm animals and has proven equally as valuable as other grains for the production of beef, pork, mutton and milk. In the feeding of wheat to farm animals, the best results are secured by

coarsely grinding or pulverizing the grain instead of feeding it whole. The main use of wheat, however, is to manufacture flour for human food. It is used more extensively as human food than any other cereal.

It has been found from extensive experiments conducted by the United States Department of Agriculture that the highest degree of digestibility and nutritive value of wheat are secured when the bran and indigestible fibre are removed from the flinty portions of the kernel. The human digestive tract is unable to digest wheat bran; animals, however, with greater digestive powers are capable of doing so. Wheat produces one of the cheapest, most nutritious and most wholesome of foods.

HARRY SNYDER,

Chemist, Russell Miller Milling Company.

**WHEAT INSECT PESTS.** Insects injurious to growing wheat-crops. These number from 50 to 100 different kinds in the United States alone, many of which have been imported from the Old World; and they represent a wide variety of forms and classes. The most important, probably, are flies, more or less closely related to the house fly and mosquito; and of these the Hessian fly is the most dreaded and widespread. This is a small fly (*Cecidomyia destructor*) of the family *Cecidomyiidae*, the larva of which is very destructive to wheat, barley and rye, but does not attack oats. It is named from the unfounded belief that it was brought to America from Europe (where it is native, and has been a pest for centuries) in the baggage of the Hessian mercenaries employed against the Americans in the war of independence. The female fly is about a tenth of an inch in length. Its body is brown, with the upper parts, the thorax, and the head of a darker shade, approaching to black. The wings are dusky gray, and are surrounded with fringes. The male is somewhat smaller than the female and has longer antennæ. The female flies usually lay their eggs on the young plants twice in the year, in May and September, the maggots being hatched in from four to 14 days. These work themselves in between the leaf-sheath and the stem and fix themselves near the lowest joints, often near the root, and suck the juices of the stem, so that the ear falls down at a sharp angle. These maggots turn to pupæ ("flaxseed") from which the flies develop in about 10 days; those of the fall brood hibernate in the pupa state, and are ready to begin their depredations with the early sprouting of the spring crop. In view of these habits,

wherever the presence of these insects is suspected, the winter wheat should be cut as late as possible, or the early plant "trap" strip at one side of the field. The flies will lay their eggs, and the volunteer wheat should be destroyed and burned.

Other true flies attacking wheat and grain-crops are mainly of the family *Oscinidae*, which contains a large number of species with variable habits, those of interest in connection mainly inhabiting the grain and grasses. Here belongs the European wheat stem-miner, which is of Europe, so terribly destructive both in Britain and on the Continent, and in this country whose depredations are significant or local or obscure. That one of the most thoroughly studied is the "wheat bulb-worm" or "wheat stem-miner" (*Meromyza americana*), which has been a constant evil ever since civilized agriculture here. It is a native of the whole of America, apparently, originally feeding on wild grasses. In the middle latitudes of the United States three annual broods of this insect are more farther south, but only one in Canada. The life-cycle of this insect in the wheat-belt of the United States, according to Webster, is as follows: The winter is spent in the larval stage, and the short pupa coming in May brings the emerging adults at the time when the female is ready to place her eggs on the plants where they are on hatching, will make their way to the stem and succulent stem just above the upper joint. By the time the straw has ripened the insects have ceased to require food and pass through the pupal stage, the adults of this brood appearing in July. Eggs are now deposited on wheat and grass, and, owing either to the retarding effects of meteorological conditions or a diversity of food of the larvae, perhaps, the emerging of the adults is prolonged throughout a period extending from August through September until late in the fall. At this period the fall wheat offers a desirable and inviting plant to the female fly on which to place her eggs with a prospect of her offspring having an abundant food supply. It is from eggs deposited during this period that the winter over in the plants and give rise to the May-June generation of flies. It is this brood that is of more especial interest to the farmer, as it is very seldom that the Hessian fly causes serious injury to grain except in fall and early spring. The effect on the plant is to kill the young plants the central spindle leaf is killed, the detached portion turning first yellow and later brown, then falling and dying, leaving the outer lower leaves uninjured. In Hessian-fly attacks the flattened leaf is absorbed and does not remain all in the young wheat in autumn, so that there need never be any confusion of these two insects in fall wheat, as is often the case on the full-grown straws is even more distinguishable. When attacked by the Hessian fly of this species the fully grown straw is killed at the upper joint, and all that portion of the plant including the head, the sheath except the lower part, turns to a whitish color, the remainder of

including the upper sheath, continuing uninjured and of the usual green color. The Hessian fly never affects the full-grown straws in this manner and the lesser wheat stem-maggot (*Oscinis carbonaria*) does so but rarely, so that the presence of these maggots in the straw can be easily detected shortly prior to harvest by their whitened color from the upper joint upward. The larvæ are within the stem and not outside and under the sheath, as with the Hessian fly; they are larger and of a more glassy green color than those of the lesser wheat stem-maggot, and it is only when still very young that the ordinary farmer need ever mistake them for any of the others mentioned in this article. The liability of attack from this insect is not sufficiently great to warrant expensive preventive measures. It occasionally comes in vast numbers, but no way is yet known of forestalling these epidemics. The same precautions and methods as those taken against the Hessian fly are recommended. Several other species of *Oscinis* are known, among which the American frit-fly (*O. soror*) may prove formidable hereafter, as it has already committed extensive depredations in Minnesota. The more careful and cleanly the method of farming, the less are these and other insect pests to be dreaded.

The chinch-bug is another far too prevalent plague of grain-fields; it is, indeed, regarded as the most destructive insect in the country. It is a small blackish plant-bug (*Blissus cucullerius*), with white wing-covers each marked with a dark line like a figure 6. Arising from her winter sleep in the old grass and rubbish of the fields and fence-corners, the female lays several hundred eggs on the stems and roots of the sprouting grasses and grains near her. The young hatch quickly, and in a crowd of reddish dots suck out the juices of the growing plants, causing them to wither and die. There is another brood in the fall. Severe winters and wet and cold springs reduce the numbers of this pest, and certain diseases are known which spread among the bugs and destroy them. Infected bugs have been sent from diseased districts to other regions and imparted to the bugs there with good effect. There seems to be no preventive, however, except great care in burning stubble and rubbish, keeping the fields clean, and planting as late as possible.

Another group of highly injurious insects is found in the family *Chalcididae*—a family of gall-flies with one genus (*Isosoma*), whose species prey upon growing plants of this kind and are called "straw-worms" or "joint-worms," because their larvæ attack the nodes or "joints" of the grain-stem. The species of special interest as affecting wheat is *I. grande* (or *I. tritici*). This gall-fly is about an eighth of an inch long and black, with a body shaped much like that of an ant and four dark wings. When, in the spring, the young wheat plants are only starting to throw the stem upward, the females (at that time minute and wingless) push their ovipositors through the stem until they penetrate the head of the embryo plant within and leave an egg there. The larva soon hatching devours this vital part of the plant and kills it, though the stem may continue to grow for some time. By the middle of June

the young have developed and cut their way out to appear as the adult summer form, which wander widely. These mature, winged females now deposit eggs within the stems of wheat just above the uppermost joint, where a hardy woody gall forms about the larva, within which it transforms into the pupa stage and stays on, inert, through the winter. The best preventive measure is an annual rotation of crops; next to that, the burning of the stubble, purposely left long, but this must be done not later than early September. Various other species of *Isosoma* attack other grains, especially barley and rye, and some others also injure wheat.

Purples, ear-cockle or peppercorn is a disease of British wheat, produced by a minute nematoid worm called "wheat-eel" (*Vibrio tritici*), which are placed by their parents in the germ of the seed, and cause the formation of the purplish-black galls or "cockles" which are a feature of the disease, and in which the worms are contained. When fully grown they may attain a length of a quarter of an inch.

The Department of Agriculture has issued a large number of special illustrated publications upon the insects injurious to wheat and other grains, which should be consulted. Prominent among them are Marlatt, 'The Principal Enemies of Growing Wheat' (1901); Webster, 'Insects Attacking the Stems of Growing Wheat,' etc. (1903); Osborn, 'The Hessian Fly in the United States' (1898); Webster, 'The Chinch-bug' (1898).

**WHEATEAR**, or **FALLOW-CHAT** (*Saxicola ananthe*), an European terrestrial warbler, allied to the stonechat. Its average length is six and one-half inches, and its color is gray above, the wings being tipped with black; a black streak encloses the eye and ear-coverts. The breast is brown and the under parts white. The wheatear is much sought after when in good condition as a table bird, its flesh being very delicate and is usually caught in traps. By the British peasants the wheatear's presence is regarded as a sign of ominous and unfavorable kind; and probably the fact of the nest being often found in collections of old stones in burial-places has tended to increase the superstitious feeling. The nest is buried deeply among stones or in rock-clefts, the eggs being of pale-blue color and numbering from four to six.

**WHEATLAND**, a famous estate and former residence of President James Buchanan, located a mile from Lancaster, Pa.

**WHEATLEY**, hwè'th, Francis, English painter: b. Wild Court, Covent Garden, London, 1747; d. London, 28 June 1801. In early life he carried off several premiums given by the Society of Arts and was employed by Mortimer in decorating the ceilings at Brocket Hall. He set up as a portrait painter at Dublin, and was much employed on small whole-lengths, among his sitters numbering many members of the Irish House of Commons. Becoming involved in a scandal he left the Irish capital for London and between 1765 and 1783 exhibited many pictures classed as "domestic," but his works also included the 'Riots of 1780,' the original of which perished in a fire, although Heath's engraving of it gives a good

idea of the work. As a contemporary of Morland he was superior to that painter in the refinement both of his subjects and his treatment of them, and was really masterly in his handling of equestrian portraits, such as 'The Second Duke of Newcastle and a Shooting Party.' He was elected R.A., in 1791. He was an important figure, being one of the founders of English rural genre, and painted pretty and graceful rustic figures of women and children, while his sense of landscape coloring was really exquisite.

**WHEATLEY, Henry Benjamin**, English philologist and bibliographer: b. Chelsea, 2 May 1838. He was clerk to the Royal Society (1861-79), honorary secretary to the early English Text Society (1864-72) and its treasurer (1872-1901). Besides editing for the Text Society 'The Romance of Merlin' (1865-99) and other works he is the author of 'Anagrams' (1862); 'What is an Index?' (1879); 'Samuel Pepys and the World he Lived In' (1880); 'How to Form a Library' (1886); 'London Past and Present' (1891); 'Literary Blunders' (1893); 'Historical Portraits' (1897); 'The Story of London' (1904); 'Hogarth's London' (1909), etc.

**WHEATLEY, Phillis**, Afro-American verse writer: b. Africa, about 1753; d. Boston, 5 Dec. 1794. She was brought to Boston in 1761, was purchased by Mrs. Wheatley, and, exhibiting a fondness for books, was instructed by her mistress and her daughters, and acquired for the time a superior education, reading Latin with facility. At an early age she began to express her thoughts in verse, and some of her poems written at 14 give evidence of poetic ability. At 19 she visited England, where she attracted much attention. A volume of her poems dedicated to the countess of Huntington was published there, containing her portrait and bearing the title, 'Poems on various Subjects, Religious and Moral, by Phillis Wheatley, Negro Servant to Mr. John Wheatley of Boston, in New England.' After return from England she published several poems, among others an address to General Washington. Her book was reprinted in Boston and passed through several editions. The family of Mr. Wheatley being broken up by death soon after her return, she married a negro named Peters, and her last days were spent in extreme want.

**WHEATON, hwé'ton, Frank**, American military officer: b. Providence, R. I., 8 May 1833; d. Washington, D. C., 18 June 1903. He was educated at Brown University, went to California in 1852 and studied law at Poitiers, France; lieutenant in the United States cavalry, subsequently participated in various Indian campaigns, and at the outbreak of the Civil War was promoted captain. He served with the Army of the Potomac through the war, was promoted brigadier-general of volunteers in 1862, commanded a division at Gettysburg and in the Shenandoah, and was engaged in other famous movements. He was made colonel in 1874, brigadier-general in 1892 and major-general in 1897. He was retired in the year last named.

**WHEATON, Henry**, American jurist: b. Providence, R. I., 27 Nov. 1785; d. Dorchester, Mass., 11 March 1848. He was graduated from

Rhode Island College (now Brown University) in 1802, and studied law at Poitiers. He then took up the practice of law and later served as an editor of a law journal; and in 1816 became reporter of the United States Supreme Court; his reports which were published in 12 volumes, are exceptionally complete and valuable. In 1818 he was appointed chargé d'affaires to Denmark, being the first regular diplomatic agent sent to the United States to that country, and at Copenhagen until 1835, when he was appointed Minister Resident to the court of Russia. Two years later he was made Plenipotentiary by President Van Buren. In that office he retained until 1846. His diplomatic work was most successful; in 1844 he negotiated a treaty with Germany, which, though rejected by the United States Senate, served as a basis for subsequent treaties. In 1843 he was elected a corresponding member of the French Academy, and in the following year a member of the Royal Academy of Science in Rome. He returned to the United States in 1846. His most important work is his 'Elements of International Law,' published in 1836, which has always been regarded as a standard text on the subject; numerous editions have appeared in the United States, including one by Lawrence (1855) and one by Wheatley (1882); there is also an English edition and a translation. His other writings include 'The Law of Maritime Captures' (1815); 'Life of William P. Ingham' (1826); 'History of the Northmen' (1826); 'Histoire du Droit du Gens en Europe' (1841); 'la Paix de Westphalie jusqu'au Congrès de Vienne' (1841), translated into English (1846); and 'An Inquiry into the British Right of a Right of Search of American Vessels' (1842).

**WHEATON, Loyd**, American military officer: b. Pennfield, Mich., 15 July 1862. He entered the Union army at the outbreak of the Civil War with rank as sergeant and through the war, receiving promotion through the ranks to captain in 1862, major in 1863, lieutenant-colonel in 1864. In 1866 he was appointed captain in the regular army, and subsequently employed on frontier duty, and at the outbreak of the Spanish-American War he was appointed brigadier-general of volunteers, was assigned to duty in the Philippines in 1899 and in 1900 received rank as major of volunteers. He was engaged in all important engagements in the Philippines. In 1900-02 was in command of the department of North Luzon and the Northern Philippines. He was promoted brigadier-general in 1901 and in 1902 retired.

**WHEATON, Ill.**, city, county-seat of Page County, on the Chicago and North Western Railroad, 25 miles west of Chicago. It is an agricultural and stock-raising region. The city is connected with industrial establishments connected with the production of grain and dairy products, and ships annually considerable quantities of wheat, corn, and dairy products. The water works cost originally \$60,000. The city is served by Wheaton College (Congregationalist), a school, opened in 1874, public and private schools, a public library presented by

Adams, a college library, two newspapers and a bank. Pop. 3,423.

**WHEATON COLLEGE**, located at Norton, Mass., was one of the pioneer schools for the education of women. It was founded as Norton Female Seminary by Judge Wheaton in 1834 and organized by Mary Lyon. The school was opened for students in 1835 and incorporated by an act of the General Court in 1837. The name was changed to Wheaton Female Seminary in 1839, but the institution was commonly known as Wheaton Seminary until by an act of the legislature of Massachusetts in 1912, the name was changed to Wheaton College and it was authorized to grant degrees. The school was never coeducational. Wheaton College is situated on a slight elevation and in a healthful pine-tree region. The extensive grounds include more than 100 acres of land, diversified by gardens, lawns, hedges, trees and meadows, containing an athletic field, tennis courts, basket-ball standards and other equipment for outdoor sports. The college has 20 buildings, nine of which are new brick buildings in the colonial style of architecture and six are dwelling-houses just outside the campus. The college has an endowment of about \$1,000,000. Wheaton recognizes the new intellectual needs of the home without lessening the opportunities for those who aim at professional work. It is the only small separate college for women in Massachusetts. It allows for personal association, especially between student and teacher, and for the development of individuality. It is democratic in spirit and unsectarian but thoroughly Christian. There are no secret societies. The faculty is composed of both men and women, selected not alone for their ability in research work, but primarily for their efficiency as teachers. The curriculum is carefully planned, and a matter of considerable importance is the organization of the studies of the curriculum into a group system. This affords a well-rounded course of instruction for each student and at the same time allows room for the exercise of individual taste. Wheaton College admits students on three years of Latin, the fourth year to be taken in college. With this exception all courses in Latin are elective. College mathematics is also elective. Wheaton offers a limited number of assistantships which yield various sums annually up to \$100 each, according to the service rendered.

**WHEATSTONE**, hwēt'stōn, SIR Charles, English physicist: b. Gloucester, February 1802; d. Paris, 19 Oct. 1875. He commenced business for himself in London as a maker of musical instruments and in 1823 attracted the attention of scientists by the publication in 'Thomson's Annals of Philosophy' of a paper entitled "New Experiments on Sound." In 1834 he was appointed professor of experimental philosophy in King's College, London, and in 1836 exhibited at King's College experiments showing the velocity of electricity. For this purpose he used a circuit of four miles of copper wire. These experiments suggested to him the idea of applying his apparatus to telegraphing. In 1837 with W. F. Cooke, he took out the first patent for magnetic telegraph, but no practical application of this was made till after

the Morse telegraph had been operated. Another subject that engaged much of his attention was vision, on which he published various papers, among them a memoir contributed to the 'Philosophical Transactions' in 1848, "On some Remarkable and Hitherto Unobserved Phenomena of Binocular Vision." He was knighted in 1868; was a Fellow of the Royal Society from the year 1836, and was also a corresponding member of the French Institute and honorary member of the principal academies of science in Europe. He wrote no considerable work, but was the author of numerous papers chiefly contributed to the *Philosophical Magazine* and the *Journal of the Royal Institution*.

**WHEATSTONE'S BRIDGE**, in electricity, a well-known form of the electrical bridge or balance for testing electrical resistance. See ELECTRICITY.

**WHEDON**, Daniel Denison, American clergyman, educator and editor: b. Onondaga County, N. Y., 20 March 1808; d. Atlantic Highlands, N. J., 8 June 1885. He graduated from Hamilton College in 1828. The following year he taught in Cazenovia Seminary and then was for two years tutor in Hamilton College. From 1831-45 he was professor of Greek and Latin in Wesleyan University, Middleton, Conn. Then, after pastorates at Pittsfield, Mass., and at Rensselaer, N. Y., from 1845-52 he was professor of rhetoric, logic and history at the University of Michigan, and resigned because of his abolition sympathies. He then became principal of a private school and later had two brief pastorates in New York. Though not a member of the General Conference of 1856 he was elected by that body editor of the *Methodist Quarterly Review* and book editor of the Methodist Episcopal Church. Six times he was re-elected by acclamation and served for 28 years. He was the author of 'Public Addresses' (1833-52); 'A Commentary on the New Testament' (5 vols., 1860-80; the volumes on the Old Testament are by other authors and most of the eight volumes appeared after his death); 'Freedom of the Will' (1864); 'Essays, Reviews and Discourses'; and 'Statements Theological and Critical' (edited by J. S. and D. A. Whedon, 2 vols., 1887). He was also the author of many pamphlets and articles.

**WHEEL**, Breaking on the, a horrible mode of putting to death by torture formerly in use in Europe. The condemned criminal was first fastened to two pieces of wood, in the form of a Saint Andrew's cross, with his legs and arms extended, and had the bones of his shins and thighs and of the fore and upper arms broken by blows with a bar of iron. After that he was attached to a small carriage wheel balanced on a stake, and allowed to suffer in this position till he died, sometimes several days after the breaking of his limbs. Later the punishment was so far mitigated that the criminal was put to death by a final blow on the breast, spine or neck before being exposed on the wheel, and sometimes he was strangled before even the breaking of his limbs took place. This torture was last used in Prussia about 1811.

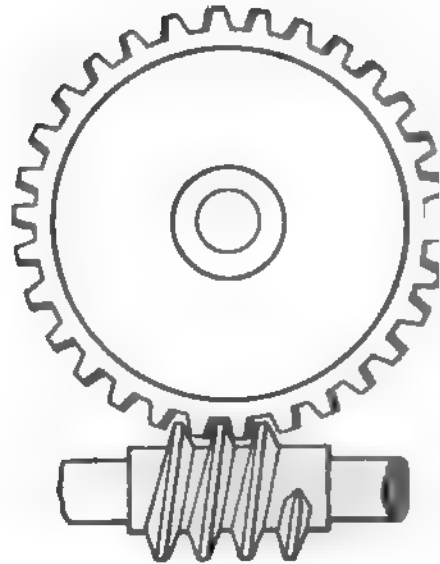

**WHEEL**, The, a popular name for the bicycle or the bicycle trade when at the height of its prosperity, about 1900.

**WHEEL AND AXLE**, one of the mechanical powers consisting of a wheel mounted on an axle, with a rope or cord wound a few times around a groove in the wheel and another rope or cord turned around the axle. The wheel having the larger diameter, a small power applied at its circumference will balance a larger resistance or force on the cord around the axle, the gain in power being proportioned to the respective diameters of the wheel and the axle. The common winch, the windlass, the capstan and the treadmill are so many applications of the wheel and axle; and the same principle may be adapted to a train of wheel-work wherein motion is regulated and power acquired.

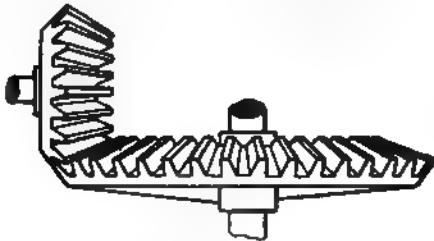

**WHEEL-BUG**, any of several species of conenose (q.v.).

**WHEEL-GEARING**, a general term applicable to all forms of mechanical devices by which motion is transmitted by means of toothed or cog wheels. The different parts of

the part to which that motion is transmitted the driver is termed the "follower." The mechanism consists of a series of elementary combinations, the motion transmitted to each piece from the

Screw or Worm Gearing.

Bevel Gearing.

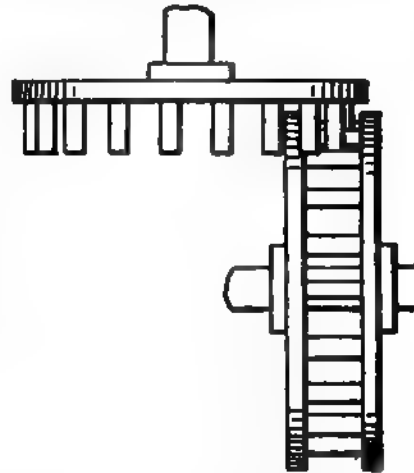

a machine may transmit motion to each other by "direct contact" or by means of an "intermediate connector"; in the latter case the motion of the connecting part being usually of no

preceding it, and so on throughout the series; therefore, in order to ascertain the motion of a complete machine, the "velocity ratio" and the "directional relation" of each combination of the series has to be determined. Factors depend upon the mechanical connection of the two parts, forming the combination, are absolutely independent of the true velocity or directions of the parts themselves, and may or may not be liable to continual variation. For example, in two circular wheels, in

Spur Gearing.

importance since the desired object is simply the proper relative motion of the two parts thus connected. In elementary combinations of either kind, the part receiving the motion from the source of power is termed the "driver" and

Face Gearing.

with each other, and rotating upon the velocity ratio is constant. If the velocity of one is twice that of the other, the velocity of the larger will be one-half that of the smaller, but during any changes of

whatsoever since the length of the respective radii of the wheels remains unchanged, the velocity ratio at any instant is the same. As to the directional relation, if the wheels are in internal contact, they will rotate in the same direction, and if in external contact, in opposite directions; but in both cases the directional relations will remain unchanged regardless of any change of the absolute direction of the driver. On the other hand, if the wheels are elliptical, while the directional relation will remain constant, the velocity ratio will be subject to variation according to varying lengths of the contact radii. All elementary combinations may be divided into four classes — rolling contact, sliding contact, link work and wrapping connections. The first two are direct methods, while the two last named communicate the motion through intermediate connectors.

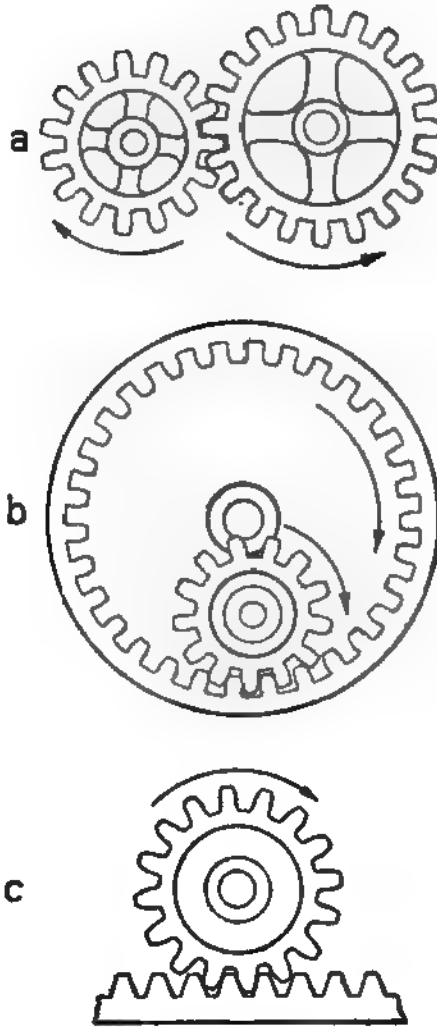

The theoretical forms required to transmit motion by rolling contact are cylinders, cones and hyperboloids of revolution. In the various forms of "friction gearing," employed to drive light machinery, the rolling pieces are made of different materials, one of wood and the other of iron, or one of them is covered with leather or rubber, and the necessary amount of adhesive contact is secured by adjusting the bearings of the pieces or by the application of weights or springs. It is impossible to transmit motion against any considerable amount of resistance by means of smooth surfaces, and toothed gears are, therefore, generally employed and may be conveniently divided into five classes, according to the form of the pitch or contact surfaces of the equivalent toothed wheels, and designated as "spur" gears, "bevel" gears, "skew" gears, "screw" or "worm" gears and "face" gears.

In spur gearing, the wheels act upon each other in the same plane; the pitch surfaces are cylinders and the teeth engage along straight lines parallel to the sides of the cylinders. If one is considerably smaller than the other it is usually termed the "pinion," while the larger is commonly known as the "wheel." When the teeth are formed on the inner side of the wheel, or convergent to its centre, it is called an internal wheel. Wheels in external contact rotate in opposite directions, but wheels in internal contact rotate in the same direction. As the diameter of the pitch circle of a "wheel" is increased its curvature decreases and finally becomes a straight line and results in a "rack and pinion" combination.

In bevel gearing the wheels act upon each other at an angle; the pitch surfaces are cones and the teeth engage along straight lines which pass through the common vertex of the two cones. When the angle of contact is equal to 45 degrees they are called "mitre gears." In skew gearing the axles are neither parallel nor intersecting, the pitch surfaces are hyperboloids of revolution, and the teeth engage in lines approximating to the general direction of the common element of the hyperboloids. Owing to the difficulty of constructing the teeth, this class of gearing is not much used, and where the conditions require their application, two pairs of cone wheels are generally employed.

In screw gearing the axles of the cylinders are neither parallel nor intersecting, and the pitch surfaces are in contact only at one point.

In its practical form it is known as "endless screw" or "worm gear," and is commonly employed to convert rapid into slow motion. The mounting of the screw prevents any other motion except that of rotation, so that at each complete turn of the screw a tooth of the engaging wheel passes across the line of centres, and there being no limit to this action, the wheel continues to rotate so long as the screw is turned around its axis.

Spur Gearing.

- (a) External Contact.
- (b) Internal Contact (annular).
- (c) Rack and Pinion.

In face gearing, the teeth consist of pins arranged in a circle and fastened to a flat circular plate attached to an axis. The wheels act at right angles to each other and the points of contact are situated only upon the surfaces of the pins. Prior to the introduction of bevel gears, it was the method usually employed to transmit motion between axes that were not parallel, but at the present time it is almost

exclusively used in connection with modern mill machinery.

There are a great many other forms of gearing which are adapted for various purposes. Of them the stepped, twisted, spiral and differential gearing are the most important. (For description of differential gearing see *AUTOMOBILE*). The particular advantage of the last-named over ordinary spur gearing is the slight friction and the consequent lack of wear of the teeth. Bevel gears of this type have been used with great advantage in mowing machines. By the substitution of epicycloidal and hypocycloidal curves and involutes for the circular arcs in the forms of the teeth, the rolling contact action of the circles, in its relation to the production of a constant velocity ratio, is replaced exactly by a sliding contact action. The teeth of all gear wheels are designed upon the principles of these curves, so that when running together their action is smooth and free from vibration and shock.

**Bibliography.**—For specific information relative to the application and design of gearing consult Rankine, 'Machinery and Millwork'; Grant, 'Teeth of Gears'; Kent, 'Mechanical Engineer's Pocket Book' (1903); and Stahl and Woods, 'Elementary Mechanism' (1903).

**WHEEL WINDOW**, in *architecture*, a circular window with radiating mullions resembling the spokes of a wheel.

**WHEELER**, hwe'ler, **Andrew Carpenter**, American journalist and author: b. New York, 4 July 1835; d. Monsey, Rockland County, N. Y., 10 March 1903. He began newspaper work on the *New York Times*, and later became city editor of the Milwaukee (Wis.) *Sentinel*. Soon after the outbreak of the Civil War, he went with the Federal army as correspondent for several eastern and western papers; and afterward, following two years of incidental writing for the Chicago press, joined the *New York Leader* staff, then numbering many prominent names. For a time he wrote for the *Leader* dramatic critiques over the signature "Trinculo." Then he became dramatic and musical critic of the *World*, and began writing the articles signed "Nym Crinkle." Later still he was on the staff of the *Sun*. As "Nym Crinkle" he published 'The Chronicles of Milwaukee' (1861); 'The Toltec Cup'; 'The Primrose Path of Dalliance,' 'The Iron Trail,' and other books. Latterly, having withdrawn from journalistic work, he published under the new pseudonym "J. P. Mowbray" (or J. P. M.), two series of essays and two books of fiction—'A Journey to Nature' (1901); 'The Making of a Country Home' (1902); 'Tangled Up in Beulah' (1902), and 'The Conquering of Kate' (1903). His authorship of these later works was not known until after his death.

**WHEELER**, Arthur Oliver, Canadian topographer: b. near Kilkenny, Ireland, 1860. He was educated at Ballinasloe and Dulwich colleges and in 1876 became a government land surveyor in Canada. He was later appointed Dominion topographer, and made irrigation and phototopographical surveys of Alberta near the Alaskan boundary. He also explored and surveyed the territory now known as Mount Robson Park. He is an enthusiastic mountain climber and has scaled most of the peaks of the Canadian Rockies. He was one of the

organizers of the Canadian Alpine Club was its president in 1906-10. He edited *Canadian Alpine Journal* in 1906-13; author of 'The Selkirk Range' (1903) joint author of 'The Selkirks: a Gai Mountain Pilgrims' (1911).

**WHEELER**, Benjamin Ide, American lege president: b. Randolph, Mass., 15 July 1875, and afterward studied for four years in Germany, traveling also in Greece. He subsequently engaged as an instructor at Harvard and Cornell, and in 1886 was appointed professor of philology at the latter university, receiving the chair of Greek in 1896. In 1896 he accepted the directorship of the American School of Classical Studies, at Athens, Greece, and since 1899 has been president of the University of California. He was also of the department of philology in *Journal of Universal Cyclopædia* and in *Macmillan's Dictionary of Philosophy and Psychology* has written 'The Greek-Noun Accent' 'Analogy and the Scope of its Influence in Language' (1887); 'Introduction to the History of Higher Education in the United States' (1896); 'Life of Alexander the Great' (1910), etc.

**WHEELER**, Claude L., American physician and editor: b. Montreal, 5 May 1854, d. Brooklyn, 30 Dec. 1916. He was graduated Laval University, Quebec, and then studied medicine at McGill University in Montreal where he served on the staff of the Montreal Eye and Ear Hospital. In 1902 he became assistant editor of the *New York Journal*, succeeding Dr. Frank P. Foster as editor in 1909. His publications include brilliant discussions of medical topics.

**WHEELER**, Henry Lord, American chemist: b. Chicago, Ill., 14 Sept. 1867. He graduated at Yale University in 1890 as his Ph.D. there in 1893, later specialized in chemistry at the universities of Chicago and Leipzig. Since 1908 he has been professor of chemistry at Yale University. He was elected to the National Academy of Sciences in 1909. Author of many papers dealing with organic chemistry, which have usually appeared in the *American Chemical Journal* and in the *Journal of the American Chemical Society*.

**WHEELER**, James Rignall, American archaeologist: b. Burlington, Vt., 15 Feb. 1871, d. New York, 8 Feb. 1918. He was graduated at the University of Vermont in 1894 and received the degree of Ph.D. from Harvard University in 1885. He went to Greece during the summer while taking courses at Harvard from 1882 to 1883 attended the American School in Athens. In 1885-86 he attended the universities of Berlin and Bonn, Germany. On his return to America he became an instructor in Greek and Latin at Johns Hopkins University and in 1889 an instructor in Greek and Latin at Harvard. From 1889 to 1895 he was professor of Greek in the University of Vermont which his father had been president. He was elected secretary of the

of Classical Studies at Athens and after 1901 he served as chairman of the managing committee. In 1895 he came to Columbia University as professor of Greek, serving in that capacity until 1906, when he succeeded to the chair of archaeology and Greek art. From 1906 until 1911 he was acting dean and dean of the Columbia College of Fine Arts. During those years he was also associate editor of the *American Journal of Archaeology*. With Prof. Harold Fowler, he was joint-author of 'A Handbook of Greek Archaeology,' and contributed various articles on archaeology and philology to professional periodicals.

**WHEELER, Joseph**, American soldier and statesman: b. Augusta, Ga., 10 Sept. 1836; d. Brooklyn, N. Y., 25 Jan. 1906. He was graduated from the United States Military Academy in 1859; served in several scouting expeditions against Indians in Kansas and New Mexico; in February 1861, resigned his commission, and in April following was made a first lieutenant of artillery in the army of the Confederate States. In September, he became colonel of the 19th Alabama infantry. He commanded a brigade at Shiloh (6-7 April 1862), distinguished himself by his services, and was selected to command the rear guard when, at the end of the second day's fighting, the Confederates retired from the field. By reason of his success as commander of the rear guard when the Confederates withdrew from before Halleck's army (30 May 1862), and his equally successful command of the salient outpost at Corinth, led to his appointment as head of the cavalry of Bragg's army. As such he led the advance in every forward movement of the forces and commanded the rear guard with the exception of Hood's Nashville campaign (winter of 1864). In August and September 1862 he led Bragg's advance into Kentucky, and detained Buell until Bragg had captured Mumfordsville, with cannon, munitions and supplies. At Perryville (see PERRYVILLE, BATTLE OF, and THE KENTUCKY CAMPAIGN OF 1862), 8 Oct. 1862, Wheeler commanded the cavalry and displayed great energy and skill. He led a brilliant charge and captured a battery. Ordered to cover the retreat of Bragg's army, he made possible that general's successful escape, with large supply trains, to Cumberland Gap. Rosecrans on 25 December moved forward to attack Bragg before Murfreesboro. Wheeler skilfully retarded Rosecrans' advance, and during the battle (31 Dec. 1862 to 3 Jan. 1863) (see STONE RIVER, or MURFREESBORO) was, in the words of Bragg's official report, "pre-eminently distinguished." He was commissioned major-general in January 1863, and in June and July took a prominent part in the battles attending Bragg's retreat to Chattanooga. At Chickamauga (19-20 September) he defeated the right flank of Rosecrans' army (20 September), penetrated to the rear, and defeated Watkins in a severe combat. On 20 September he crossed the Tennessee and captured substantially all of Rosecrans' ordnance and supply trains. He fought in the Knoxville campaign in November, and on the 27th with Cleburne, defeated Hooker at Ringgold Gap. During the spring of 1864 he aided in opposing Sherman's advance from Dalton to Atlanta, commanding the cavalry of the Confederate right wing, under Johnston and Hood. He fought

almost daily, his force frequently being dismounted. On 28-31 July he defeated a Federal raiding force under Generals Stoneman, Garrard and McCook, capturing many prisoners and all the transportation and artillery. On 10 Aug. 1864 he was again in the rear of Sherman's army, capturing supplies, burning bridges and destroying railways. He went as far as the Kentucky line in eastern Tennessee, and then proceeded to northern Alabama. It was impossible, however, to arrest Sherman's advance or destroy his communications. Wheeler was then sent in advance of Sherman's army, keeping the Confederate government and commanders advised of the enemy's movements and preventing foraging parties from leaving the main force. He thus restricted the spoliation of Georgia to a comparatively narrow area. He defended Macon, Augusta and Savannah, and defeated Kilpatrick at Aiken and Johnsonville. During the operations in North Carolina in 1865, he distinguished himself at Bentonville (19-21 March) by opening an avenue for Johnston's retreat. He was promoted lieutenant-general on 28 February, and commanded Johnston's cavalry until the surrender of the Confederate armies. Subsequent to the war he studied law, and followed that profession and the occupation of a planter until 1880, when he was elected a Democratic representative in the 47th Congress. He was unseated by W. M. Lowe in 1882, but on Lowe's death not long after was re-elected, and in 1884 was returned to the 49th. He was continually re-elected, and was serving at the outbreak of the Spanish-American War. In April 1898 he volunteered for duty, and on 4 May 1898 was commissioned major-general of United States volunteers. On 14 May he was assigned to command the cavalry division, United States army, about to leave for the invasion of Cuba. He planned, and commanded in, the battle of Las Guasimas, 24 June 1898, and participated in the battle of San Juan, 1-2 July 1898. He commanded the cavalry division of the Fifth corps in Cuba from 22 June to the surrender at Santiago, 17 July. Subsequently he was in command of the troops at Montauk Point, L. I., and from 7 October to 3 December was in command of the Fourth army corps at Huntsville, Ala. From August 1899 to January 1900 he commanded the First brigade, Second division, Eighth corps, in Luzon, Philippine Islands. On 16 June 1900 he was commissioned brigadier-general, United States army, and in June-September commanded the Department of the Lakes. On 10 September he retired from the service. His publications include 'Account of the Kentucky Campaign' (1862); 'History of the Santiago Campaign' (1898); a 'History of Cuba' (1899), and eight volumes of Congressional speeches (1883-98).

**WHEELER, Nathaniel**, American inventor: b. Watertown, Conn., 7 Sept. 1820; d. Bridgeport, Conn., 31 Dec. 1893. He was engaged with his father in the manufacture of carriages, but about 1848 joined Allan B. Wilson in manufacturing sewing machines. In 1852, on the establishment of the Wheeler and Wilson Manufacturing Company, he became its president, and by his practical knowledge of machinery and ability as an organizer soon built up what was then the largest sewing machine factory in the world. Subsequently he served for six sessions

in the Connecticut legislature; and invented and patented many improvements in sewing machines, railway cars, wood-finishing processes, etc.

**WHEELER, Wayne Bidwell**, American temperance worker: b. Brookfield, Ohio, 10 Nov. 1869. He was graduated at Oberlin College in 1894 and took his degree in law at the Western Reserve University in 1898. He became field secretary of the Ohio Anti-Saloon League in 1898, and superintendent of that organization in 1902. He later served on the executive committee of the national organization.

**WHEELER, William Adolphus**, American lexicographer: b. Leicester, Mass., 14 Nov. 1833; d. Roxbury, Mass., 28 Oct. 1874. He was graduated from Bowdoin in 1853, was engaged in teaching for several years, and subsequently assisted Joseph E. Worcester (q.v.) in the preparation of his 'Dictionary' (1856-59). He was afterward occupied with the revised edition of Webster's 'Dictionary' (1864) for which he compiled 'Explanatory and Pronouncing Vocabulary of the Names of Noted Fictitious Persons and Places, including Familiar Pseudonyms, Surnames, etc.,' which was issued separately in 1865. In 1867 he was appointed assistant superintendent of the Boston Public Library. He left unfinished an encyclopedia of Shakespearean literature and an index to anonymous literature entitled 'Who Wrote It?' The latter, completed by C. G. Wheeler, was published in 1881. He edited Hole's 'Brief Biographical Dictionary' (1866); a 'Dickens Dictionary' (1873); and also 'Familiar Allusions' (1882).

**WHEELER, William Almon**, American legislator: b. Malone, N. Y., 30 June 1819; d. there, 4 June 1887. He was educated at the University of Vermont and was admitted to the bar in 1845. He was United States district attorney of Franklin County in 1847-49 and in 1849 was elected as a Whig to the State assembly, but in 1856 he joined the ranks of the then newly-organized Republican party. He was a member of the New York assembly in 1858-59; in 1860 was elected to Congress; in 1867 was president of the State Constitutional Convention; was re-elected to Congress 1869 and served until 1877, taking a prominent part in the adjustment of Southern affairs under the Reconstruction Act and settling the political difficulties in Louisiana by the well-known "Wheeler Compromise." He was Vice-President of the United States under Hayes in 1877-81.

**WHEELING**, hwē'ling, W. Va., city, county-seat of Ohio County, on the east bank of the Ohio River, in the northern pan-handle and in the same latitude as Philadelphia, 60 miles southwest of Pittsburgh. It is on the Baltimore and Ohio Railroad, and its branch lines; the Pennsylvania System; the Wheeling and Lake Erie Railroad of the Wabash System; the Ohio River and Western Railroad and the Wheeling Terminal Railway, a belt line connecting all the roads. It is the largest and most important city in West Virginia. The land area is 2,050 acres and it has an elevation of 660 feet above sea-level. Part of the city, a beautiful residential section, is on Wheeling Island, which is over a mile long and contains 400 acres. A historic suspension bridge connects the island (the Seventh Ward) with the

main part of the city, and two o bridges span the west channel of the island to the Ohio side. Eighty trolley lines in Wheeling and suburbs population of 75,000 in West Virginia, Ohio and western Pennsylvania in connection with the city as a commercial centre. steamer connections with the Ohio and wha river points and commands a la trade. Among the features of interest, courthouse and city hall combined (for the State Capitol), the new government building, the site of old Fort Henry, the Hermonument, Wheeling and Mozart parks, Catholic cathedral, Elks Home, Y. M. and Y. W. C. A. buildings, Market and Board of Trade building, the high school the Home for the Aged. The excellent portation facilities of the city, the large of natural gas piped from West Virginia Pennsylvania fields, the extensive coal fields in the vicinity and the abundance of raw materials nearby have served to make Wheeling important manufacturing city. In 1918 Wheeling had over 200 manufacturing establishments capitalized at \$40,000,000, in which were employed 18,000 persons, receiving an annual cost of \$24,000,000. The yearly cost of raw materials used was \$38,000,000 and the finished products were valued at \$75,000,000. The chief manufactures are iron and steel products, glass, tobacco, leather, lumber products, and carriages. There are also print tanneries, packing-houses, canning factories national reputation and the largest prosthetic remedy company in the world.

Wheeling has 42 churches, embracing numerous denominations. It is the seat of the Catholic diocese of Wheeling. Besides the public school system, including a school, opened in 1897, there are the Institute, Mount de Chantal Academy (Catholic), two business colleges, several schools and a public library with 40,000 volumes. Bethany College and the West Liberty Normal School are located a few miles north. There are in all 51 schools, valued at \$3,000,000. The city has the North Wheeling and City hospitals, two private hospitals, several orphanages, a day nursery and homes for the aged and friendless. There are 16 theatres, 16 banks, four daily newspapers, four flourishing Y. M. C. A., with a commodious building, an active chamber of commerce embracing numerous secret and fraternal organizations. The commission form of government was put into effect in 1917. The waterworks cost \$1,000,000 and are maintained at a cost of \$100,000 annually. The city's annual budget is about \$1,000,000. The assessed valuation of real estate is \$782,200. There are 30.20 miles of paved streets and 20.25 miles of paved alleys, and 100 miles of macadamized and graded roads. Wheeling was one of the first towns founded on the Ohio River and is supposed to have derived its name from the Wheeling Indian, a name of Wheeling C. The first settlement was made in 1769 by Zane. In 1774 a stockade fort — Fort Mifflin named in honor of Patrick Henry — was built here as a defense against the Indians.

Sept. 1777 this fort was attacked by an Indian force of 300, who were repulsed, but 15 of the settlers were killed. In 1781 another attack was made. On 11 Sept. 1782 the fort was again besieged by a force of 40 British soldiers and 260 Indians, who continued the attack for two days, but were forced to abandon the fight. In 1769 the town was laid out by Colonel Zane and in 1795 was incorporated. In 1836 it was chartered as a city and became widely known as an important trading post on the great National Road and the Ohio River. In 1861 Wheeling was made the capital of the "restored government of Virginia" by the people of Virginia opposed to secession. It was the State capital from 1863 to 1870 and again from 1875 to 1885. Pop. 47,000.

H. P. CORCORAN,

*Assistant Manager, Wheeling Chamber of Commerce.*

**WHEELING AND LAKE ERIE RAILWAY, The.** Corporate name of a transportation company organized 14 Dec. 1916 in Ohio as successor to the Wheeling and Lake Erie Railroad Company, whose property was sold under foreclosure on 30 Oct. 1916, and purchased on behalf of the bondholders in accordance with the plan of reorganization of 20 Sept. 1916. The lines owned by the company are as follows: Main line, Toledo to Terminal Junction, Ohio, 210.05 miles; main line: Cleveland to Zanesville, Ohio, 144.20 miles; Aetnaville Extension: Terminal Junction to Aetnaville, 2.75 miles; Huron Branch: Huron Junction to Huron, Ohio, 12.80 miles; Steubenville Branch: Warrenton to Steubenville, Ohio, 13.65 miles; Sherrodsville Branch: Canton to Sherrodsville, 45.47 miles; Massillon Branch: Orrville Junction to Run Junction, 22.09 miles. Lines operated: Chagrin Falls Branch: Falls Junction to Chagrin Falls, 8.19 miles; leased line: Adena Railroad: Adena to Saint Clairsville Junction, Ohio, 20.93 miles; trackage rights: Cleveland, Cincinnati, Chicago and Saint Louis Railroad from Linndale to Wellington, 32 miles, making a grand total of 512.13 miles. In 1917 the equipment comprised 205 locomotives, 79 passenger cars, 893 box-freight cars, 80 stock cars, 7,291 coal cars, 126 flat cars and 535 service cars. The railroad moved in the same year 14,218,970 tons of revenue freight, of which 62 per cent came from mines, 27.62 per cent were manufactures and 2.05 per cent agricultural products. The average haul per ton was 106.5 miles and the average rate per ton per mile was 0.623 cents. The system carried 1,623,885 passengers in 1917, at an average rate per passenger per mile of 1.65 cents. The total operating revenue was \$11,028,904, the total operating expenses \$7,378,212, leaving the net revenue from operations \$3,650,692. The net income was \$1,113,895.

**WHEELOCK, hwe'łök, Eleazar,** American clergyman: b. Windham, Conn., 22 April 1711; d. Hanover, N. H., 24 April 1779. He was graduated at Yale in 1733, and from 1735 to 1770 was pastor of the Second Congregational Society in Lebanon, near Columbia, Conn. In 1754 he opened a missionary school for Indians, known from Joshua Moor, who gave for its use a building and two acres of ground, as Moor's Indian Charity School. This he removed in August 1770 to Dresden (now Hanover), N. H.,

founded Dartmouth College, to which a charter had been granted in 1769.

**WHEELOCK, John,** American educator: b. Lebanon, Conn., 28 Jan. 1754; d. Hanover, N. H., 4 April 1817. He was son of Eleazar Wheelock (q.v.). He entered Yale in 1767, but became a member of the new Dartmouth College at Hanover, N. H., and was graduated with the first class in 1771. In 1775 he was elected a member of the provincial assembly, in 1777 was appointed a major in the New York forces and soon after lieutenant-colonel in the Continental army. In 1778 he led an expedition against the Indians. In 1779 he was elected president of Dartmouth College and remained there, except two years, till 1817. He bequeathed half his large estate to Princeton Theological Seminary. He published 'Essay on the Beauties and Excellencies of Painting, Music and Poetry' (1774); 'Sketches of the History of Dartmouth College' (1816), etc.

**WHEELWORK.** See CLOCK.

**WHEELWRIGHT, hwel'rit, Edmund March,** American architect: b. Roxbury, Mass., 14 March 1854; d. 16 Aug. 1912. He was graduated at Harvard University in 1876 and later studied architecture at the Massachusetts Institute of Technology and in Europe. He was afterward connected with different architects in Boston, Albany and New York, and from 1883 conducted his own business in Boston. He was senior partner in the firms Wheelwright and Haven and Wheelwright, Haven and Hoyt. He was city architect of Boston in 1891-95. He designed the Hartford Bridge, the Cambridge Bridge, the Boston Opera House, Jordan Hall at Boston, the Cleveland Museum of Fine Arts, and was one of the architects of the Boston Museum of Fine Arts. He wrote 'Municipal Architecture in Boston' (2 vols., 1898); 'School Architecture' (1901).

**WHEELWRIGHT, John,** American Puritan clergyman: b. Lincolnshire, England, about 1592; d. Salisbury, N. H., 15 Nov. 1679. He was a graduate of Cambridge and vicar of Bilsby, near Alford, Lincolnshire; but in 1636, being driven from his church by Archbishop Laud, he emigrated to Boston, Mass., where the same year he was chosen pastor of a branch of the Boston church at Mount Wollaston, in what is now Quincy. The celebrated Anne Hutchinson (q.v.) was his sister-in-law, and he partook of her views. Differences of opinion led to personal animosities between him and John Wilson, the pastor of the Boston church; and the General Court appointed a fast in January 1637, partly to heal these dissensions. On this occasion Wheelwright preached in Boston and, as his enemies asserted, denounced the ministers and magistrates. The General Court pronounced him guilty of sedition and contempt, for which in November 1637 he was banished from the colony. In 1638 he formed a settlement on the banks of the Piscataqua, which he called Exeter. After a residence of five years here the town was declared to be within the limits of Massachusetts, and he removed with a part of his church to Wells in the district of Maine. In 1644 his sentence of banishment was revoked, in consequence of some acknowledgments on his part, and he returned to that

colony in 1646 and settled in Hampton. In 1654 he published his 'Vindication.' About 1657 he went to England, where Cromwell, who had been his college classmate, received him cordially; but he returned in 1660 and in 1662 settled as pastor in Salisbury, N. H. His 'Writings,' with a memoir, edited by C. H. Bell, were published by the Prince Society in 1876.

**WHELAN**, hwé'lan, Richard Vincent, American Roman Catholic prelate; b. Baltimore, Md., 28 Jan. 1809; d. there, 7 July 1874. He was educated at Mount Saint Mary's College, Emmitsburg, Md., and at the Seminary of Saint Sulpice, Paris, where he was graduated in 1831. He was ordained to the priesthood in 1832, returned to the United States and in 1832-35 was a professor at Mount Saint Mary's. He was engaged in missionary work at Harper's Ferry and other towns in Virginia and Maryland in 1835-40, and in the latter year was consecrated bishop of Richmond. He built a theological seminary near Richmond, founded schools and academies, built a cathedral at Wheeling, and in various ways greatly improved the condition of his diocese. When the diocese was divided in 1850 he became bishop of Wheeling. The Wheeling diocese then contained but two churches and two priests, with no supplementary institutions of any kind. At his death it possessed 48 churches, 40 stations for religious services, 29 priests, six academies, four convents, a hospital, an orphan asylum and a college. He was present at the Vatican Council of 1869-70 and opposed the definition of the dogma of papal infallibility, considering the time inopportune.

**WHELK**, a gastropod mollusk of the genus *Buccinum* and order *Ctenobranchiata*. The large or common whelk (*B. undatum*) is of common occurrence on both sides of the north Atlantic, and is distinguished by the shell having its canal notched, and the mouth or aperture of large size. The whorls of the shell, which has a thick horny epidermis, are few and rounded. In England these animals are largely used for food and bait, and are caught in "creels" baited with garbage, but in America they are not eaten. The eggs are contained in egg-cases, bundles of which are common on the sea-coasts; each capsule contains several eggs, some of which develop and devour the others. The red whelk, or "roaring buckie" of the Scotch (*Fusus antiquus*), belongs to the family *Fusida* (q.v.). The tulip whelk (*Fasciolaria tulipa*) is very richly colored and inhabits the tropical seas. The purple whelk (*Purpura lapillus*) is so named from its affording a part of the dye which made Tyre of old so famous.

**WHEN LILACS LAST IN THE DOOR-YARD BLOOMED.** Swinburne called this elegy on Abraham Lincoln by Walt Whitman "the most sonorous anthem ever chanted in the church of the world." Such praise may be too high for the poem, but it can hardly be denied a place among the great elegies of the English language. The highly artistic and carefully wrought structure of the poem somewhat corresponds to that of a symphony, in its varied and intricate harmonies, and its three leading motifs of the lilacs, the evening star and the song of the thrush, which, constantly recurring, finally

merge into the poet's song of love, regret and consolation. As in much of Whitman's best work, nature is here not a mere background, but is suffused with human feeling and becomes one with it. The scenes before the house in the dusk and in the swamp with the thrush, the vast panorama of country and town which loved Lincoln and which now laments him—these are not mere pictures, but realities; are not apart from the human passions of the poem, but an essential ingredient of them. The free verse, with its irregular rhythms and its lines of varying length, permits an immense range of emotional effects, of exquisite melodies and vast harmonies, perhaps not attained by any other poem in American literature; and Whitman's characteristic magic of phrase weaves its spell in such lines as "the yellow gold of the gorgeous, indolent, sinking sun," and "the huge and thoughtful night." The elegy gives no such intellectual estimate of Lincoln as Lowell attempts in the 'Commemoration Ode'; it is simply a song,—a lament and a consolation. Its emotion appears as spontaneous and unstudied as it is sincere and unrestrained; but for all that the poem is none the less a nobly planned and carefully executed work of art.

MARION TUCKER

**WHERRY**, hwér'i, William Macky, American soldier; b. Saint Louis, Mo., 13 Sept. 1836. He was educated at the University of Missouri and studied law; served through the Civil War; and was present at the battles of Wilson's Creek, Dallas, Kenesaw Mountain, Atlanta, Jonesboro, Nashville, and at the surrender of Gen. J. E. Johnston. He was brevetted brigadier-general of volunteers in 1865, mustered out of the volunteer service in 1866, and appointed captain in the regular army and subsequently served on frontier duty. In the war with Spain in 1898 he took part in the battle of San Juan Hill and in the capture of Santiago. He was promoted brigadier-general, United States of America, 7 Jan. 1899, and was retired the same month. He has published 'Battles and Leaders of the Civil War' (1888-89).

**WHERRY**, a light, shallow boat, for plying on rivers; also a light, half-decked fishing vessel, used in different parts of Great Britain and Ireland.

**WHETSTONE**, any stone used for sharpening tools. Sandstones and fine mica schists form the coarser kinds. Silicious clay rocks, and particularly the fine compact rocks made of quartz-mud, such as the Arkansas stone or novaculite, form the more desirable varieties for oil-stones and delicate hones. See **SEDIMENTARY ROCKS**; **SCHISTS**.

**WHEWELL**, hú'él, William, English scholar; b. Lancaster, 24 May 1794; d. Cambridge, 6 March 1866. He was graduated from Trinity College, Cambridge, in 1816, and in due course became Fellow and tutor of his college. He labored with Herschel, Babbage and Pe to raise the standard of mathematics in the university, and wrote textbooks which were celebrated. From 1828 till 1832 he was professor of mineralogy, and in 1838 was elected Knightbridge chair of moral philosophy, which he held till 1855. In 1841 he became master of Trinity and in this position labored and successfully to obtain for the natu

moral sciences a better recognized position among the studies of the university. He became Fellow of the Royal Society in 1820, and was one of the first members of the British Association, of which he was president in 1841. Whewell was a strong, healthy, clear-headed man, possessed of a vigorous and capacious intellect, and endowed with extraordinary powers of acquiring and retaining knowledge. The extent and variety of his attainments were very unusual. Yet there was nothing superficial about his learning, notwithstanding the well-known *mot* of Sydney Smith, that "science was his forte and omniscience his foible." Besides other gifts, he built at his own expense, and presented to his college, a *hostel*, or collection of chambers for undergraduates. His principal writings include the Bridgewater treatise 'Astronomy and General Physics, considered with reference to Natural Theology' (1833); 'History of the Inductive Sciences' (1837); 'Philosophy of the Inductive Sciences' (1840); 'Novum Organum Renovatum'; 'Indications of the Creator'; 'History of Scientific Ideas'; 'Elements of Morality, including Polity'; 'Lectures on Systematic Morality'; 'Architectural Notes on German Churches'; 'On Liberal Education in General'; 'Lectures on the History of Moral Philosophy in England'; 'Philosophy of Discovery'; 'History of Moral Philosophy'; 'Platonic Dialogues for English Readers.' He was the author of the well-known anonymous essay, 'The Plurality of Worlds.' Consult Todhunter, 'Whewell: an Account of His Writings' (1876); 'Life,' by Mrs. Stair Douglas (1881); Clark, 'Old Friends at Cambridge and Elsewhere' (1900).

**WHEY**, a clear, straw-colored liquid, consisting of the part of milk which remains fluid after the milk has been curdled by the use of rennet in cheese making, or by the action of the acid in the natural souring of the milk. Its average percentage of solids is 6.96, of which .36 per cent is fat, .84 per cent proteins and 5.76 per cent chiefly sugar, with a trace of salts and other matter. It is ordinarily used in the feeding of swine and calves, not because of any great nutritive value but as a means of conserving economically the solids it contains. Whey cheese is made by evaporating the liquid and then adding cream. In large cheese-making establishments the whey is sometimes put through a separating process to collect the fat, which is made into a good quality of butter. Milk sugar is also made from whey in factories large enough to make it profitable. Various cooling drinks are made from whey, and in some European countries "whey cures" for certain diseases consist of drinking a prescribed amount of the liquid, and sometimes of bathing in it.

**WHIGS**, a word of British origin, used for many years to designate members of an American political party. It had previously been used in America in colonial and Revolutionary times to indicate those who were opposed to the attempts of the British Crown to deprive the Americans of their political and commercial rights. It disappeared with the close of the Revolution, and did not appear again until the National Republicans, successors to the Federalists (q.v.), adopted the name of Whigs. Those Whigs who considered the slav-

ery question settled by the compromise of 1850 were called in Massachusetts "Cotton Whigs," and in New York "Silver Grays." The Whigs continued to exist as one of the two great parties until the election of 1852, which was followed by a division on the slavery issue, the anti-slavery Whigs joining the Republican party, and the others making common cause with the Democracy.

The term was prominent in British political history for nearly two centuries to designate the political party which advocates such changes in the Constitution as tend in the direction of democracy. Defoe thus accounts for the origin of the name: "The use of it began then when the western men (the peasantry of the West Lowlands of Scotland), called Cameronians, took arms frequently for their religion. Whig is a word used in those parts for a liquor (*whig*, Scotch for *whey*), which the men used to drink . . . and so became common to the people who drank it. It afterward became a denomination of the poor harassed people of that part of the country, who, being unmercifully persecuted by the government, against all law and justice, thought they had a civil right to their religious liberties, and therefore resisted the power of the prince (Charles II)." Monmouth was sent to quell the insurrection, and "at his return he found himself ill-treated for having used the rebels too mercifully; and Lauderdale told Charles, with an oath, that the duke had been so civil to the Whigs because he was a Whig himself in his heart. This made it a court word, and in a little time the friends and followers of the duke began to be called Whigs."

A different origin is, however, assigned to the term. Sir James Balfour, in writing of an outbreak which occurred in 1648, in his own day, calls the enthusiasts "whigamores," and Burnet, who was then five years old, offers the following explanation: "The southwest counties of Scotland have seldom corn enough to serve them throughout the year, and the northern parts producing more than they need, those in the west come in the summer to buy at Leith the stores that come from the north; and from a word, whiggam, used in driving their horses, all that drove were called the whigamores, and shorter, the whiggs. After the news came of Duke Hamilton's defeat (in 1648), the ministers animated their people to rise and march to Edinburgh; and they came up, marching at the head of their parishes, with an unheard-of fury, preaching and praying as they came. . . . This was called the whigamores inroad, and ever after that, all that opposed the court came in derision to be called whigs; and from Scotland the word passed to England." The Whigs brought about the Revolution of 1688-89, and established the Protestant succession; they were chiefly instrumental in obtaining the abolition of the slave-trade and slavery, the repeal of the Test and Corporation Acts, Catholic emancipation, Parliamentary and municipal reform, the repeal of the corn-laws and similar measures. The term Liberals is now generally applied to the representatives of this party; the extreme section of the party, who agitate for sweeping innovations, usually have a more or less close connection with the Whigs, and have

adopted the name of Radicals. See **POLITICAL PARTIES**.

**WHIN.** See **FURZE**.

**WHIN, WHINSTONE**, a mining term for intruded igneous or basaltic rock generally of a firm texture and resistant character. The great Whin Sill of Northumberland is a typical example.

**WHINCHAT**, European warbler (*Pratincola rubetra*), allied to the stonechat, and is named from its frequenting the neighborhood of whin and furze bushes. It is also called furzechat. It possesses a long white streak, passing across the sides of the head, which, as well as all the upper parts of the body, is colored brown. The lower parts are yellowish. Its length is usually under 10 inches; four to six green-blue eggs are laid in ground nests. Its song is very sweet and it has been known to imitate the song of other birds. Its range is not confined to Europe, as it is found in many parts of Africa and occasionally in western Asia.

**WHIP-SNAKE**, a light brown harmless snake (*Masticophis flagelliformis*) with whitish tail, closely related to the blacksnake; called also coach-whip. It is found in the southern United States and Mexico, and is especially abundant in Texas. Its name is given it on account of its general appearance; and the more ignorant Indians and negroes believe it will whip or lash its adversary with its tail. It runs with the utmost swiftness, and has the general habits of a blacksnake (q.v.). A group of very slender poisonous African and Asiatic tree-snakes, the *Dipsadinae*, are called whip-snakes in some books. They are elapine and poisonous and conceal themselves aided by their leaf-green color, in bushes where they dart upon birds, lizards, insects, etc., unsuspecting of their presence.

**WHIPPING or FLOGGING.** See **FLOGGING**; **WHIPPING-POST**.

**WHIPPING POST**, a post at which punishment was inflicted by the law of England, and until recent years in the State of Delaware, chiefly for minor offenses. The criminal law in England enumerates several offenses for which whipping at the post may be inflicted on males under 16. A subsequent act enacts that when the offender is under 14 the number of strokes is not to exceed 12. In Scotland no person above 16 is to be whipped for theft or crime committed against person or property. In connection with the pillory (q.v.) it flourished in America in colonial times and was commonly employed on blacks in slavery. In Delaware robbery, theft and other crimes were for many years punished by whipping. See **FLAGELLATION**.

**WHIPPLE**, hwip'1, **Abraham**, American naval officer: b. Providence, R. I., 1733; d. near Marietta, Ohio, 29 May 1819. In the French and Indian War he commanded the privateer *Gamecock* and on one cruise alone captured 23 prizes. He was in charge of the expedition which on 8-9 June 1772 destroyed the British armed schooner *Gaspee*, commanded successively the *Columbus*, the schooner *Providence* and the frigate *Providence*, and from 1775-79 with the schooner *Providence* took

more prizes and destroyed more any other commander in the colony. With the frigate *Providence* he evaded surveillance and succeeded in getting to important dispatches for France, and performed the daring exploit of carrying vessels from a merchant fleet of 100 sail, eight of which reached Boston safely brought about \$1,000,000 when sold. He commanded the naval forces at Charleston in 1780, but was captured and held a until the close of the war. He commanded a vessel which in 1784 unfurled the first A flag on the river Thames.

**WHIPPLE**, Edwin Percy, American and critic: b. Gloucester, Mass., 6 1819; d. Boston, 16 June 1886. After ordinary education, he began writing for papers, in 1837 became a clerk in a brokerage office and from 1837 to 1841 superintendent of the reading-room of the Chants' Exchange. In 1843 he first attracted attention by a critical panegyric on M in the *Boston Miscellany*, and in Oct that year entered upon his successful career as a lecturer, chiefly on literary topics. He contributed much to reviews and journal publishing in 1848-49 two volumes of 'Essays and Reviews,' including discussions of 'Poets of the 19th Century,' 'Byron,' 'Choate' and 'Henry Fielding.' In 1850 he was literary editor of the *Boston* (a newly-established daily). The greater part of his work is composed of essays on literature and authors, though he treated of other subjects with an almost equal discrimination. 'Literature of the Age of Elizabeth' probably shows him to best advantage, his estimates of the moderns are also taking and for the most part just. His characterizations were penetrative, and at times effectively expressed. He lacked, however, a large extent, originality and power, another's declaration that 'with the perception of Lowell and Matthew Arnold, the ablest critical essayist of his time' now be accepted. Among his further contributions are 'Literature and Life' (1 small volume of lectures; 'Character and Characteristic Men' (1866); 'Success and Conditions' (1871). Three books appear humorously, 'Recollections of Eminent Men and Other Papers' (1887), with an introduction by C. A. Bartol; 'American Literature: Papers' (1887), with a brief introduction by Whittier, and containing the centennial of American literature written in the *Harper's Magazine*; and *Outlooks on Literature and Politics* (1888). Contributors by T. W. Higginson in the *Atlantic* lviii. 345, and by T. W. Hunt in the *thea Sacra*, l. 30.

**WHIPPLE**, Henry Benjamin, A Protestant Episcopal bishop: b. Adams County, N. Y., 15 Feb. 1822; d. Ft. Minn., 16 Sept. 1901. Ill health prevented entering college, for which he had planned and he engaged in business for several years. In 1847 he began a theological course and took priest's orders in the Episcopal Church in 1850 and was rector of Zion Church, N. Y., 1850-57 and of the church of

Communion, Chicago, 1857-59. In October 1859 he was consecrated first bishop of Minnesota. He very soon afterward organized the Seabury Mission at Faribault, out of which have since been developed the cathedral of Our Merciful Saviour, Seabury Divinity School, the Shattuck School for boys, and Saint Mary's Hall, a school for girls. Bishop Whipple was widely known as "the apostle to the Indians" on account of his labors among them both for their material as well as spiritual welfare. By the Indians he was called "Straight Tongue." He thoroughly understood the Indian character and at the time of the Sioux massacre in 1862 insisted that the trouble came directly from the false dealing of the whites with the Indians. In 1876 he secured the Sioux treaty, opening up the best portions of Dakota to white settlement, and his advice in regard to Indian affairs was sought by every President from Lincoln to McKinley. In his 'Lights and Shadows of a Long Episcopate' (1899) the character of the Indian problem will be found very fully treated. Bishop Whipple traveled extensively and was well known and highly regarded in England, while in his own country he was beloved and respected by men of every creed.

**WHIPPLE, Squire**, American civil engineer: b. Hardwick, Mass., 24 March 1804; d. Albany, N. Y., 15 March 1888. He was graduated from Union College in 1830 and engaged in canal and railway surveying. He patented in 1840 an iron bridge truss of the bowstring type, several of which were built over the Erie Canal. After 1852 he built several bridges known as the "Whipple trapezoidal type," and in 1872 took out a patent for a lift drawbridge, one of which was built over the Erie Canal at Utica. He wrote 'The Way to Happiness' (1847); 'Treatise on Bridge Building' (1847); and 'The Doctrine of Central Forces' (1866).

**WHIPPLE, William**, American soldier and politician: b. Kittery, Me., 14 Jan. 1730; d. Portsmouth, N. H., 28 Nov. 1785. Before 1751 he was captain of a merchantman trading with the West Indies and making voyages to Africa for slaves. But in 1759 he set up as a merchant at Portsmouth, and in 1775 was chosen a delegate to the New Hampshire provincial congress. He was also made a member of the provincial council of safety. In January 1776 he was elected to the Continental Congress, continuing to hold his seat until September 1779, and signing the Declaration of Independence. As brigadier-general of New Hampshire troops, he commanded a brigade in the operations against Burgoyne in 1777, and assisted in negotiating the terms of the surrender of the British general. Commanding the New Hampshire forces, he co-operated with Sullivan in the campaign against the British in Rhode Island in 1778. From 1782 to 1784 he was superintendent of finance for New Hampshire, and from 1782 until his death a judge of the Superior Court. He was president of the commission for the adjustment of the dispute between Connecticut and Pennsylvania regarding the Wyoming Valley region.

**WHIPPOORWILL**, a North American nightjar (*Antrostomus vociferus*). In this genus the rictal bristles are greatly developed and

reach far beyond the tip of the small, weak bill, and sometimes they are fringed. The nostrils are not tubular as in *Nyctidromus*. The whippoorwill is ordinarily 10 inches long with a spread of wings of about 18 inches, the mouth bristles are simple, the tail long and rounded, and the soft lax plumage closely and delicately mottled with gray, black, white and yellowish brown, the female with the tips of the outer tail-feathers tawny, the same parts in the male white. These birds inhabit the United States and British provinces east of the plains, and breed chiefly northward, throughout most of this area. Being migratory, they reach the Middle and New England States in May. The whippoorwills are strictly nocturnal, but usually become quiet by midnight, except on moonlight nights when they continue active till dawn; but at all times they are most vociferous during the early evening. The song is a clear, energetic whistle, aptly syllabified in the name, strongly accented on the last syllable, and is repeated many times; then, after a short pause begins anew. They fly noiselessly in pursuit of flying insects, skimming low over stone walls and bushes, or even alighting on the ground to pick up an insect. Large moths, nightflying beetles and insects frequenting forest borders are their chief food. When they pass close to a person at night they may be heard to utter a low murmuring sound. Unlike the great majority of birds they always perch along and not across a bough, a peculiarity which they share with other weak-footed birds. Whippoorwills do not fly abroad during cloudy days like the night hawk, and as a consequence their appearance is unknown to many persons to whom the song is quite familiar. No nest is made, and the two elliptical, creamy white eggs, marked with brown and lavender, are laid in a depression on the bare ground, or a log. When danger threatens the old birds often carry the eggs or young in their mouth to a place of safety. A much larger species of similar colors and habits, but more southern in its range, is the chuck-will's-widow (*A. carolinensis*); (q.v.). In this species the rictal bristles are provided with lateral filaments.

**WHIPTAIL SCORPION**. See SCORPION.

**WHIRLIGIG BEETLE**. See WATER-BEETLES.

**WHIRLPOOL**, a circular eddy or whirling current in a stream or the sea, of considerable dimensions, produced by the configuration of the channel, by meeting currents, by winds meeting tides, etc. There are some very celebrated whirlpools, such as Charybdis, in the strait between Sicily and Italy; and the Malström, off the coast of Norway. When the agitation is increased by high tides or winds they sometimes become dangerous to navigators. But large modern vessels cannot be sucked into any whirlpool, like some of the small craft of the ancients.

**WHIRLWIND**. See CYCLONE; WATER-SPOUT.

**WHISKY**, the name applied to a well-known liquor distilled from corn, barley, wheat, oats and other grains; potatoes, beet and other roots and sometimes molasses and subsequently refined, colored and flavored by various processes. However under regulations under the

Federal Food and Drug Act the name whisky alone is limited to grain distillates. Whisky from malt alone is made in the Scotch distilleries as follows: The malt is bruised upon cylinders and the quantity intended to be mashed is put into the mash pan, water at a temperature of about 170° F. being then added. After two or three hours' agitation the whole is left to repose for an hour and a half, and then the worts are drawn off to about one-third of the water employed. About two-thirds of the first quantity of water of a somewhat higher temperature is put into the pan, and the agitation is renewed for about half an hour. After a second period of repose these second worts are drawn off. Both infusions are now cooled down as quickly as possible to the temperature of 80° or 70° to prevent souring; the wort is cooled down by being exposed in shallow coolers to currents of air, or by being passed through serpentine tubes surrounded with cold water. More water may be let into the pan, and a third wort drawn off, which may be fixed with the other worts, or used instead of water for the first infusion of malt. The quantity of saccharine matter converted into alcohol depends upon the proportion of ferment or yeast introduced into the worts; if too little be used, a portion of the sugar will remain undecomposed; if too much, the spirits will have an unpleasant taste. Generally the worts are let down at the specific gravity of 1.050 or 1.060, and at a temperature of 60° to 50°. For every 100 gallons a gallon of good porter yeast is added and thoroughly incorporated by agitation. An hour after the addition of the yeast fermentation begins to show itself by a ring of froth around the edges of the vat, and in about five hours frothy bubbles cover its whole surface. Large vats generally afford a better result than small ones, owing to the equality of the fermenting process. It is considered good worts when the specific gravity comes down to that of water and superior worts when it falls to 0.995. In about 48 to 60 hours the wash begins to get clear and comparatively tranquil, and is then ready for distillation. In its simplest form the still consists of a copper boiler into which the wash is poured. This vessel is furnished with a close head terminating in a bent tube which passes in a spiral form through a vessel filled with cold water. (See DISTILLATION). On the application of heat to the still the spirit begins to rise in vapor at 175°, along with more or less steam. These vapors are condensed in passing through the spiral tube, and trickle in fluid form into a receiver. The product of this first distillation is called low wines. This is again distilled at a lower temperature, which gets rid of part of the water and of the fetid oils that had come over with the alcohol. Great purity and strength can only be obtained by repeated distillation. The casks or packages into which these spirits are put are never charred, as in America, but preference is given to empty wine or rum casks which impart both flavor and color, and when plain casks are used, flavoring and coloring is accomplished by means of blending wines. If nothing whatever is added to the spirits which are put in plain casks, the coloring and flavoring is attributable to the tannic acid extracted from the wood, and the oxidation of the aldehydes in combination with the ethyl alcohol.

In the United States, Kentucky, Maryland and Pennsylvania whiskies, or those represented to be such, constitute the majority of those consumed for drinking purposes, either medicinal or otherwise. Kentucky whiskies are known as Sour Mash, Sweet Mash and Bourbons and Pennsylvania and Maryland whiskies as Eastern Ryes. At the head of the various processes of distillation, for excellence of quality of the spirit produced thereby, stands that known as "fire copper," which is the method that originally established the high reputation of whisky in these States; those since employed, while giving a larger yield of spirit to the bushel of grain, procure it at the expense of the quality and flavor thereof. In this process the corn and rye meals are scalded or mashed, with hot spent beer, which is the liquid residue of the previous distillation. The mash is then allowed to cool to the proper temperature, when malt is added, and the mash, diluted with a sufficient quantity of water, is left to ferment the time established by law. The diluted mash when fermented is called beer. The beer is distilled in three different ways. In the very smallest distilleries, it is sometimes boiled in copper stills, over wood fires; the vapor, passing through a copper coil or worm, immersed in cold water, is condensed and delivered into a receiver. The condensed liquid is called low wines or singlings. Singlings contain only a small amount of spirit. This manner of boiling the beer is seldom used, as the large quantity of grain contained in the beer makes it apt to cake in the still; and, becoming scorched, it gives the whisky a strong, smoky flavor, a very little of which, however, is not considered objectionable. The singlings are doubled or again distilled in small copper stills, or doublers, over wood fires and the vapor again condensed in a copper worm, whence it is delivered into the receiving cistern. Another name for doublings is high wines. The usual way of distilling sour mash whisky is to boil the beer in a wooden still by admitting steam, the vapor being condensed into singlings; the singlings are doubled as above. In the third way the beer is boiled in a copper still by steam confined in a copper pipe placed inside the still. The singlings are doubled in small copper stills, over wood fires, in the same manner described. This latter way is considered a great improvement, as it avoids both the scorching of the grain in distilling the beer and the admission of live steam, while it preserves all the characteristics so highly prized in "sour-mash, fire copper" whiskies. The yield by the sour-mash process is from two to three gallons to the bushel of grain.

Most whisky is made by the process known as "steam." In this the corn and rye meals and malt are mixed with water in the mash-tub, where they are scalded with direct or live steam, introduced by means of a perforated pipe at the bottom of the tub. When fully scalded the mash is cooled down and run into the fermenting tubs. Fresh yeast is used in fermenting, which gives the name of "sweet mash." The still is made of wood and divided into two or three compartments. When the still is charged a certain amount of beer is placed in each compartment, live steam is admitted into the lower, which boils the beer, and the vapor from it ascends through a curved pipe into the

compartment above, where its continued reception boils the charge therein contained; the vapor from this again ascends into the next compartment above, where the same process is repeated. The vapor then passes through a pipe into a wooden doubler, where it boils the low wines; and the vapor arising thence passes into a copper worm, where it is condensed and then run into the whisky cistern. Only one worm is used and one condensation made. Highwines, as well as whisky, are manufactured by this process. The yield is from three and a half to four and a half gallons. In making whisky by the "steam copper" process, the mash is made and fermented and the beer boiled in the same manner as for the "steam" process. The same wooden still is used; but, instead of the vapor from the upper compartment passing directly into a wooden doubler, it is run through a worm and condensed into singlings, which are doubled in a copper still by live steam, or by steam confined in a jacket around the still, or sometimes by fire underneath.

In locating a distillery a full supply of clear, bright water that contains the proper chemical qualities is the first consideration. It is well known to both chemists and practical distillers that water containing a large quantity of sulphate of lime, earthy carbonates and no organic matter is best adapted to distilling. The lime and carbonates being dissolved in the acid generated during the fermentation of the mash mostly pass off in the form of carbonic acid gas and leave the water soft and best suited for extracting the active properties of the malt and grain. Great care has to be taken in the selection of the grain to have it well developed and sound. Musty or unsound grain is fatal to the production of fine whisky, and its defects become more prominent as the whisky increases in age. Those distillers most careful to manufacture only fine goods use the grain that is grown in their own section of the country in order to have both the grain and water spring from the same kind of soil. Successful fermentation requires of the distiller not only constant attention, but also extensive knowledge both of the principles of chemistry and of practical results. It is exceedingly injurious to allow the fermentation to be prematurely concluded or to proceed too long. As a general rule, the slower the fermentation and lower the heat at which the distillation is carried on the finer and purer will be the spirit. The mash being made and fermented, and the beer distilled by whatever process, the whisky is collected in the cistern and thence run into barrels, under the control of the United States inspector, and in the custody of the United States storekeeper, who has also charge of it while in the bonded warehouse, till the tax is paid. Barrels, and the cooperage thereof, require much attention, and must be made of well-seasoned oak. For highwines they are not charred, but for whisky they should be well charred, as the char has some peculiar chemical effect on the character and ripening of the whisky that is very desirable.

The subsequent purity of the product depends largely upon the care exercised by the distiller in stopping the distillation when the temperature of the vapor rises above the boiling point of ethyl alcohol and water and certain flavoring bodies depending upon the material employed.

The process of fermentation which precedes that of distillation produces a number of alcohols radically different from ethyl alcohol (which, with water, is the body of whiskies) and which seriously serve to contaminate the product. These are usually referred to by the distiller in America as the "heads" and "tails," because the former have a lower boiling point than that of ethyl alcohol, and the latter a higher boiling point, as a result of which a careful distiller can separate them from the main body of the distillate which is to be preserved.

In England these heads and tails are called "feints." Among these is fusel oil, from which it is very desirable that the spirit should be freed as much as possible. This may be partially accomplished by the action of charcoal and heat, which are the principles underlying the barrel-charring process of refinement and maturation. If, however, the fusel oil contents are too large to start with, they will never be sufficiently reduced by such process to make the product wholesome and palatable. In such case, they can only be removed or reduced by a subsequent process of rectification, including redistilling and the passage of the spirits through leach tubs. It follows, therefore, from the process of manufacture, that the fusel oil contents or percentage of impurities is not fixed or constant, and this fact led to the process called blending. Under the present system of Internal Revenue Laws in the United States distilled spirits can be sold only by one who qualifies thereunder as a wholesale liquor dealer, and such person may also be a rectifier. A rectifier is one who rectifies, purifies or refines distilled spirits, or who merely mixes without refining. Whenever it is found that whisky which has been subjected to the barrel-charring process still contains an excessive quantity of fusel oil, or has acquired an excessive quantity of tannic acid, it can only be corrected by redistillation or other rectifying processes or by the addition thereto of ethyl alcohol and water (termed for commercial purposes either "neutral spirits" or "cologne spirits") which contains no fusel oil and no tannic acid. One effect of charring a barrel is to produce a coating of a gummy, resinous substance beneath the char and next to the hard wood which is classed as caramel and which not only imparts a flavor, but produces about two-thirds of the color usually obtained by spirits which have been stored in such a barrel for a length of time. The other one-third of the color is imparted by the tannin or flavescin which the spirits extract from the wood.

Since neutral spirits are seldom put in charred barrels, they retain their original color, which is water white, and when they are mixed with the whisky which has been colored, it necessarily lightens the color which has to be restored by the addition of plain caramel. Harmless flavorings are sometimes added to modify or soften the effect of the tannin, which is a severe astringent. On account of their diminished toxicity, smoothness which sometimes results from the addition of sugar, and improved flavor which results from diluting or diminishing the tannic acid, acetic acid and fusel oil, blends are considered by some more desirable than a simple whisky.

The bulk of the so-called straight or simple

Whiskies in America are made by adding water to the highwines or doublings in the receiving cistern until they are reduced to "100 proof" or "proof,"—approximately half ethyl alcohol and half water,—and then storing them in charred barrels.

Highwines contain higher alcohols known as "impurities," created during the process of fermentation. If these impurities are removed from the highwines, the spirit is then termed "neutral," but that term is properly applied to it only so long as it is kept in its original condition, free from any coloring or flavoring matters. To insure this result, neutral spirits are stored in paraffined or waxed barrels. Neutral spirits when put into charred barrels are converted into whisky, but milder in flavor and less fiery than whisky produced from high wines. Being unsuitable for blending purposes, such whisky is seldom produced in America, although all foreign whiskies partake more of its characteristics than of whisky produced from highwines.

The recent custom of steam-heating warehouses in which whisky in charred barrels is stored increases the proof very materially. If kept in damp storage, the proof would diminish. Whisky ranges in proof from 70 to 120, but all spirits that have been subjected to the process usually recognized as producing whisky are considered whisky without reference to their "proof," though regulations under the Food and Drugs Act require the proof to be between 80 and 110 if the actual proof is not stated.

Other than the above no standard for whisky is created by the Federal laws, but many of the States have adopted the standard which was originally laid down in the United States Pharmacopœia, which required that whisky for medicinal purposes should be approximately from 88 to 110 proof, should contain no more than traces of fusel oil from grain and oak tannin from casks, a stated limit of free acid, and show a residue from 100 C. C. evaporated on a water bath and dried at 212° F., of not more than 0.5 Gm. Blended whiskies more nearly meet these requirements than straight whiskies. The subject was omitted from the last revision of the Pharmacopœia.

Whisky, whether called "straight" or "blended," is composed of approximately half water and half ethyl alcohol, plus a color and a flavor, and the only substantial difference between the two consists in the percentage of fusel oil and tannic acid, which exists in straight whiskies in a larger amount than in blended whiskies.

According to the report of the commissioner of internal revenue for the fiscal year ended 30 June 1918, grain to the amount of 16,655,125 bushels was consumed in the manufacture of whisky, the product of which for that year in the United States amounted to 186,555,202 gallons. The distillation of grain for potable beverages was discontinued 9 Nov. 1917 under Food Control Act of 10 Oct. 1917, as a war measure, since which time only whisky previously distilled has been sold. In view of the prohibition amendment to the Federal Constitution resumption of distillation for beverage purposes is forbidden.

**WHISKY FRAUDS.** The, in American civil history, a national internal revenue scandal,

which reached its climax in 1874 through the efforts of Secretary of the Treasury D. H. Bristow. Statistics showed that for some years prior to 1874 the United States had, in Saint Louis alone, lost at least \$1,200,000 of revenue which it should have received from whisky, yet special agents of the Treasury set to work from time to time had failed to do more than cause an occasional flurry among the thieves. The Whisky Ring was organized in Saint Louis when the Liberal Republicans there achieved their first success. It occurred to certain politicians to have revenue officers raise a campaign fund among the distillers. This idea the officers modified later, raising money in the same way for themselves, and in return conniving at the grossest thievery. As it became necessary to hide the frauds, newspapers and higher officials were hushed, till the ring assumed national dimensions. Its headquarters were at Saint Louis, but it had branches at Milwaukee, Chicago, Peoria, Cincinnati and New Orleans, and an agent at Washington. A huge corruption fund was distributed among gaugers, storekeepers, collectors and other officials, according to a fixed schedule of prices. As a result of the investigation by Secretary Bristow arrests were made in nearly every leading city. Indictments were found against 152 liquor men and other private parties, and against 80 government officials, notably the chief clerk in the Treasury Department, and General Grant's private secretary, Gen. O. E. Babcock.

**WHISKY INSURRECTION,** a popular name given to a local outbreak in opposition to the excise laws passed by Congress 3 March 1791. General objections were urged against the measure, and in western Pennsylvania the inhabitants considered the tax an unfair discrimination against their particular region and raised an insurrection. It became necessary for President Washington to call out an army of 15,000 militia to subdue the rebels, who dispersed without bloodshed.

**WHISKY RING.** See WHISKY FRAUDS.

**THE WHISPERING GALLERY,** a gallery or dome of an elliptical or circular form, of peculiar acoustic qualities, arranged to echo faint sounds between certain points, the sounds being conveyed around the interior wall so that they may be readily heard, while the same are inaudible elsewhere in the interior. Thus, in an elliptical chamber, if a person standing in one of the foci speak in a whisper, he will be heard distinctly by a person standing in the other focus, though the same sound would not be audible at the same distance under any other circumstances, or at any other place in the chamber. There is a whispering gallery in the Capitol at Washington, one at Saint Paul Cathedral, London, and another at Glastonbury Cathedral, England.

**WHIST,** a well-known game at cards, clearly described by Edmond Hoyle (qv.) in his "Short Treatise on the Game of Whist" (1743). See BRIDGE.

**WHISTLE-WOOD,** a North American maple tree (*Acer pennsylvanicum*). It is a tree, or sometimes only a shrub, common in mountainous districts of the eastern U. S.

States and Canada. Generally it is found in thicket-like young woods, growing in damp rocky soil. The flowers are in long axillary racemes, and bloom late in spring, drooping under the branches. They are succeeded by strings of the two-celled winged fruits of a yellowish green tint. The slender trunks are olive-green, when older becoming a reddish-brown, striped with short, delicate streaks of white pigment, which may be scraped off, and for this reason the tree is often called striped maple; it is, however, also known as moose-wood, since the deer are fond of the young shoots when the sugary sap is flowing. The bark is easily stripped off the young branches, leaving white withes from which country folk make whistles. Other whistles are made from the bass-wood (*Tilia americana*), and the name is given in Great Britain to the mountain-ash (*Sorbus*) and to the common and sycamore maples.

**WHISTLER**, hwis'lér, **James Abbott McNeill**, American artist: b. Lowell, Mass., 10 July 1834; d. London, 17 July 1903. In 1851 he was appointed to the West Point Military Academy, which he left in 1854; and in 1854-55 was a draughtsman in the Coast and Geodetic Survey. This employment he soon quitted, going to England and thence to Paris, where in 1855-57 he was a pupil in the studio of C. G. Gleyre, an artist of Ingres' school, who "never drew a line without having first assured himself how Raphael would have proceeded." Previous to the series generally styled the "French Set," Whistler is known to have etched three plates, and other early attempts were made. The "French Set," renderings of figures, street scenes and interiors, appeared in 1858 (published by Delâtre) — 12 plates, with an etched title. But few copies were printed. In 1863 Whistler went to London and settled in Chelsea. During his earlier days there he completed the 'Thames Set' of etchings, 16 in all, treating of the craft of that stream and the quaint buildings along its edge. Some rare prints of these, generally considered superior, were made before their publication in 1871. 'The Pool' and 'Black Lion Wharf' are among the best of them. He exhibited paintings frequently at the Royal Academy, one of the earliest being 'At the Piano,' purchased by the Scottish painter John Phillip for 30 guineas. In 1872 the 'Arrangement in Gray and Black' ('The Painter's Mother'), now in the Luxembourg Gallery, was accepted by the Academy only on the insistence of Sir William Boxall. Whistler sent other pictures, such as 'The Last of Old Westminster,' and 'Symphony in White III,' but he could not agree with the management of that institution, long before his death ceased to exhibit there and was never made A.R.A. Some of his best work was shown at the Grosvenor Gallery, opened by Sir Coutts Lindsay in 1877, including famous portraits, 'Irving as Philip II' and the 'Arrangements,' 'Harmonies,' and 'Nocturne,' novel in title and character. It was in 1877 that Ruskin wrote of the 'Nocturne, Black and Gold' ('The Falling Rocket'), then at the Grosvenor: "I have seen and heard much of cockney impudence before now, but never expected to hear a coxcomb ask 200 guineas for flinging a pot of paint in the pub-

lic's face" ('Fors Clavigera'). Then ensued the diverting Ruskin suit, brought for libel by the artist and heard in November 1878. The verdict was for the plaintiff, and the farthing assessed for damages Whistler afterward wore on his watch chain. The costs against Ruskin, £306 12s. 4d., were met by a public subscription. Whistler followed up the affair by his pamphlet, 'Art vs. Art-Critics,' in which he first proved his cleverness in controversial satire. He preferred to exhibit his works under conditions which he could himself direct and gave a special exhibition in 1874. Others, of either prints or paintings, were held in the rooms of the Fine Arts Society in 1880, 1881, 1883, 1884 and 1886. At the International Society, Knightsbridge, he always had chief place. He became a member of the Royal Society of British Artists in 1884 and in 1886 some "revolutionary members" made him its president. His administration improved the artistic quality of the exhibitions, but was not commercially successful, and in 1889 he failed of re-election and many of his following resigned. His explanation was characteristic: "It is all very simple. The Royal Society of British Artists has disintegrated — the 'artists' have come out, the 'British remain.'" He failed for a long time of the recognition he merited; but latterly many distinctions were conferred upon him. He was a member of the Legion of Honor and the Bavarian Order of Saint Michael, member of the Munich, Rome, Dresden and other academies; in 1900 received the unusual award at the Paris Exposition of the gold medal for etching and also for painting; and in 1902 the gold medal of honor from the Pennsylvania Academy of Fine Arts. By many Whistler's etchings have been ranked as the consummate product of his art, classed with those of Rembrandt and even said to surpass the world's greatest etcher in the process of selecting essentials and a certain subtlety in execution. He did not keep a set of proofs or memoranda of his work and probably no complete list of his etchings. The first catalogue of them appeared in 1874. Wedmore gave 214 in 1886, 268 in 1889; a supplement to Wedmore increased the number to 372. It is probable that the total is more than 400 prints. It has been said that while Rembrandt chose greater subjects, only a comparatively small part of the total number of his plates is sought by collectors, but all of Whistler's are highly esteemed by connoisseurs. "There are no failures," declares one writer; some are sketchier than others, but all are genuine expressions of Whistler's art. Whistler used an increasing economy of means; the 'First Venice Set,' published by the Fine Arts Society in 1880 (12 plates), and the 'Twenty-six Etchings' (1886), principally of Venetian subjects, though including some English also, show in this respect great difference from the 'French' and 'Thames' sets. The unflinching characteristics of the etchings are precision and flexibility of line and remarkable picturesqueness in the rendering of shade and light. Their observation and their technical skill are alike noteworthy. Of the single plates may be mentioned 'Joe,' 'Little Putney,' 'Battersea Bridge,' 'Old Chelsea' and 'Speke Hall.' Examples are to be seen in many important

public collections, including the Venice Academy, Bibliothèque Nationale, British Museum, the New York Public Library and the Dresden Gallery. In dry-point and lithography, too, Whistler was very successful. His first lithographs were made in 1877 and he greatly improved the art. His London exhibition of 1883 contained, besides etchings, a number of dry-points; in 1896 about 70 lithographs were shown at the Fine Arts Society. The Way catalogue, no longer in print and claiming to include all those printed down to 1897, gave 130, to which at least eight must further be added. The list of nearly 400 etchings and dry-points and 138 lithographs, known to be in existence, reveals a large amount of work, even supposing that the artist had done nothing else. In pastel and water-colors, Whistler wrought sparingly, although some of the Venetian pastels are the equals of anything yet attempted in that medium. His creed as a painter he stated in two series of 'Propositions,' and the lecture 'Ten o'Clock' first given in London 20 Feb. 1885. One of the propositions was that a painting had "no mission to fulfil," but was a "joy to the artist, a delusion to the philanthropist, a puzzle to the botanist." Critics he thought a herd of ignoramuses; but they had their utility—"they keep one always busy, always up to the mark, either fighting or proving them idiots." For a long time in London he was better known for his pugnacity than for his art. His arrogance, his mordant wit, his sparkling bon-mots, his striking individuality—these were sooner recognized than his genius. His fondness for sarcasm and the severity and clearness with which he lambasted those he did not like—and they were many—qualified him as a past-master in "the gentle art of making enemies." It is to be regretted that his exceptional genius was thus marred. He had in oils a broad range of subjects. There are the numerous portraits; marines ('Valparaiso Harbor'); 'Blue Wave—Biarritz'; 'The Ocean'; and landscapes of many sorts, especially those interpretative of night. His method was to apply many coats of thin color instead of one or a few of greater consistency' this guarantees to his work a superior permanence. He was above all the colorist and in pure line and color harmonies has been called one of the supreme artists. His work has repeatedly been compared to that of Velasquez, but study shows very important dissimilarities and Whistler must remain unique. He borrowed somewhat from Oriental art, though always subordinating these elements to his own ends. Among portraits not referred to is that of Carlyle, now in the Glasgow Museum, of which the philosopher observed, "weel, man, you have given me a clean collar, and that is more than Meester Watts has done." Whistler did some work in interior decoration, such as the music-room of Sarasate (Paris) and the "Peacock-room" for Mr. Leyland (London). Many fine examples of his paintings are in American galleries, public and private. His place in the history of world art cannot yet be estimated, but he may safely be put among the greatest painters of the 19th century.

McNeill Whistler' (Chicago 1909).

**WHISTLEWING**, or **WHISTLER**, a duck. See **GOLDEN-EYE**.

**WHISTON**, hwis'ton, William, English mathematician and Anglican clergyman: b. Norton, Leicestershire, 9 Dec. 1667; d. London, 27 Aug. 1752. He took his degree at Clare Hall, Cambridge, in 1690, and in 1691 was elected to a fellowship there. He was ordained a deacon in 1693, was appointed chaplain to the bishop of Norwich, and in 1698 became vicar of Lowestoft, Suffolk. He was appointed deputy professor of mathematics to Newton at Cambridge in 1701, and in 1703, upon Newton's resignation, succeeded to the Lucasian professorship. He continued to preach, but having given expression to Arian views, was in 1710 summarily expelled from his professorship and the university. He removed to London where he published 'An Historical Preface to Primitive Christianity Revived' (1711). He was thereupon prosecuted for heresy, but after proceedings lasting five years, was permitted to remain in the English Church. He subsequently engaged in lecturing upon scientific subjects, being among the first to introduce lectures with experiments in London. He founded in 1715 a society for the promotion of primitive Christianity, the meetings of which were held in his home, and afterward became a Baptist. He made a translation of Josephus (1737) which ran through many editions and wrote 'New Theory of the Earth' (1696); 'The Accomplishment of Scripture Prophecies' (1708); 'A New Method of Discovering the Longitude' (1714); 'The True Origin of the Sabellian and Athanasian Doctrines of the Trinity' (1720); 'The Testimony of Phlegon Vindicated' (1732); 'The Longitudes Found by the Ellipsis of Jupiter's Planets' (1738); 'Memoirs' (1749), etc.

**WHITAKER**, hwit'a-ker, Alexander, American clergyman: b. Cambridge, England, 1585; d. Henrico County, Va., after 1613. He was graduated from Cambridge, was for some years rector of a north of England parish, settled in Henrico County, Va., in 1611 and was active in missionary work. He baptized Pocahontas and officiated at her wedding. He wrote 'Good Newes from Virginia,' (1613), one of the first books written in the colonies.

**WHITAKER**, hwit'a-kér, **Daniel Kimball**, American editor: b. Sharon, Conn., 13 April 1801; d. 10 April 1881; grandson of the Rev. Nathaniel Whitaker. He was graduated at Harvard, 1820, studied law and settled in South Carolina, becoming the law partner of ex-Governor John Lyde Wilson. Though eminently successful as a lawyer, his preferences were for literature and he established and edited a number of periodicals, among them the *Southern Literary Journal* and *Whitaker's Magazine*. In 1841 he established at Charleston, S. C., the *Southern Quarterly Review*, which he edited until the Civil War. In 1866 he moved to New Orleans, La., and founded and for many years edited the *New Orleans Monthly Review*. He was corresponding secretary of the New Orleans Academy of Sciences.

**WHITAKER**, Edward Gascoigne, American judge: b. New York, 13 April 1853. He received his education at Southampton Academy and at a German university, and was admitted to the bar in 1876. In 1884 he was appointed deputy attorney-general of New York, which office he occupied for seven years. In 1912 he received the appointment as justice of the Supreme Court of New York, first district. As president of the State Bar Association (1897), Mr. Whitaker served on the committee concerned with international arbitration problems; was active in promoting expedient measures for the prompt publication of appellate reports, and was instrumental in establishing the system of uniform examinations for admission of students to the bar.

**WHITAKER**, John, English Anglican divine: b. Manchester, about 1735; d. Ruan-Langhorne, Cornwall, 30 Oct. 1808. He was educated at Oxford. In 1771 he published a 'History of Manchester,' and in refutation of Macpherson's theory that the modern Highlanders were descendants of the Caledonians of Tacitus, wrote his 'Genuine History of the Britons' (1772), maintaining that they were descended from an Irish colonization which followed the Roman invasion. In 1778 he was presented by his college to the rectory of Ruan-Langhorne. His most important works are 'Sermons upon Death, Judgment, Heaven and Hell' (1783); 'Mary, Queen of Scots, Vindicated' (1787); 'The Origin of Arianism Disclosed' (1791); 'The Course of Hannibal over the Alps Ascertained' (1794); 'Life of Saint Neot' (1809).

**WHITAKER**, Joseph, English publisher: b. London, 4 May 1820; d. Enfield, Middlesex, 15 May 1895. In 1849 he started a church monthly called *The Penny Post*, soon after established a theological publishing business of his own in Pall Mall, and in 1856-59 was editor of *The Gentleman's Magazine*. He founded *The Bookseller* in 1858, but his name is remembered principally in the title of 'Whitaker's Almanac,' which first appeared in 1868. The 'Reference Catalogue of Current Literature' was started by him in 1874.

**WHITAKER**, Nathaniel, American Presbyterian clergyman: b. Long Island, N. Y., 22 Feb. 1732; d. Woodbridge, Va., 21 Jan. 1795. He was graduated from Princeton in 1752, entered the ministry and became pastor of a church at Chelsea, Conn., and visited England

in 1765-66, accompanied by Samson Occom, an educated Indian, for the purpose of soliciting funds for the establishment of an institution of learning in America for the use of the Indians. His mission resulted in the foundation of Dartmouth College. He was subsequently engaged in pastoral duties in Massachusetts and in Maine, finally removing to Virginia. He was a staunch Whig and ardently supported the cause of the colonics during the Revolution. Several of his sermons were published.

**WHITAKER**, Ozi William, American Protestant Episcopal bishop: b. New Salem, Mass., 10 May 1830; d. 9 Feb. 1911. He was graduated from Middlebury College, Vermont, in 1856 and from the General Theological Seminary in 1863. He took priest's orders in the last-named year, was rector of Saint John's, Gold Hill, Nev. (1863-65), of Saint Paul's, Englewood, N. J. (1865-67), and of Saint Paul's, Virginia City, Nev. (1867-69). In 1869 he was consecrated missionary bishop of Nevada, was transferred to the diocese of Pennsylvania as assistant bishop in 1886, and upon the death of Bishop Stevens in 1887 became bishop of Pennsylvania.

**WHITBREAD**, hwit'brëd, **Samuel**, English politician: b. Cardington, Bedfordshire, 1758; d. 6 July 1815. He was educated at Oxford and Cambridge and entered the House of Commons in 1790 as Whig member for Bedford. He at once made his mark as an able advocate of Parliamentary reform, religious and civil liberty, the abolition of slavery and similar liberal causes, and as a strong opponent of Pitt's war policy. He took a leading part in the impeachment of Viscount Melville in 1805-06 and against Lord Chatham for his mismanagement of the Walcheren Expedition in 1809. He committed suicide after being engaged in a very trying controversy over the rebuilding of Drury Lane Theatre. Consult 'The Creevy Papers' (1903).

**WHITBY**, hwit'bi, Canada, capital of Ontario County, a town and port of entry on Lake Ontario, at the southern terminus of the Whitby and Port Perry Railway, and on the Grand Trunk Railway, 30 miles east of Toronto. It has iron foundries, tanneries, manufactories of agricultural implements, mill machinery and musical instruments and carries on an active agricultural trade. Pop. 2,500.

**WHITBY**, England, seaport in the North Riding of Yorkshire, 48 miles north-northeast of York, at the mouth of the Esk, which divides it into two parts. The houses are ranged on bold acclivities and an ancient restored cruciform church stands on the verge of a lofty cliff; there are several modern churches and Non-Conformist chapels; a town-hall, courthouse, museum, temperance hall, seamen's hospital, etc. The harbor is spacious and commodious, having wet and dry docks, etc. The manufacture of jet ornaments is carried on, a very hard black ossified wood being abundant in the neighborhood. There are also yards for ship and boat building and productive sea fisheries. In 657 Saint Hilda founded her famous priory on the site of Whitby, then called Streoneshalh, and in it was held the important Synod of Whitby in 664, at which the Roman usage as regarded Easter was adopted (see EASTER). The poet

Cædmon (q.v.) was a resident in this monastery, of which nothing now remains, though the choir, north transept and part of the nave of an abbey erected on the site in the 11th century are still standing. The ruins are in early English style and extremely beautiful. The neighborhood is rich in picturesque scenery and interesting features. Pop. about 13,000. Consult Kitchen, 'Whitby Abbey and Other Essays' (1904).

**WHITCHER**, hwich'ér, **Frances Miriam Berry**, American humorist: b. Whitestown, N. Y., 1 Nov. 1811; d. there, 4 Jan. 1852. She was married in 1847 to Rev. B. W. Whitcher, an Episcopal clergyman of Elmira, N. Y. Her 'Widow Bedott's Table-Talk' first appeared in Neal's *Saturday Gazette*, published by J. C. Neal, author of 'Charcoal Sketches.' After her death these and other humorous articles of the journalistic type, once very popular, were collected in 'The Widow Bedott's Papers' (1855) and 'Widow Sprigg, Mary Elmer and Other Sketches' (1867).

**WHITE**, **Andrew Dickson**, American diplomat, educator and author: b. Homer, N. Y., 7 Nov. 1832; d. Ithaca, N. Y., 4 Nov. 1918. He was graduated from Yale in 1853 and studied at the College of France, Paris, and at the University of Berlin. He was attaché of the American legation at Saint Petersburg in 1854-55 at the time of the Crimean War, and in 1857, shortly after his return to the United States, became professor of history and English literature at the University of Michigan. In 1863 he returned to Syracuse and was elected to the New York State senate, where he was especially interested in educational legislation, obtaining the passage of bills organizing the State normal system and providing for the codifying of the educational laws. He also had an important part in the founding and organization of Cornell University, contributing \$300,000 for the purpose, and also procuring for that institution the national land grant for agricultural colleges; in 1867 he became president of the university and was also professor of history. He maintained his connection with Cornell until 1885, when he resigned both presidency and professorship. He gave to the university his excellent historical library of about 30,000 volumes, and on the acceptance of this gift the departments of history and economics were reorganized as the White School of History and Political Science. While president of Cornell, he was also active in public affairs; in 1871 was one of a commission to study and report on the desirability of annexing Santo Domingo; in 1878 was honorary commissioner to the Paris Exposition, and in 1879-81 Minister to Germany, during which time he had leave of absence from the university. In 1892-94 he was Minister to Russia; in 1896 was one of the commissioners to investigate the Venezuela boundary question, and in 1897-1902 was Ambassador to Germany, holding that position longer than any other American Minister. Before his retirement from the German Ambassadorship he was elected a member of the Berlin Academy of Sciences. In 1899 he was president of the United States delegation to The Hague Peace Conference. He retired from public life in 1902 and passed his remain-

ing years at Ithaca. His published works include 'History of the Warfare of Science against Theology' (1898), an enlargement of his 'Warfare of Science' (1876); 'Studies in General History'; 'The New Germany'; 'European Schools of History'; 'Paper Money Inflation in France' (1876); 'Chapters from My Diplomatic Life' (*Century Magazine*, 1903); 'Autobiography' (1905); 'Seven Great Statesmen in the Warfare of Humanity with Unreason' (1911).

**WHITE**, **Arthur Silva**, English publicist: b. London, 1 Feb. 1859. He was secretary to the Royal Scottish Geographical Society and editor of the *Scottish Geographical Magazine* in 1884-92, and for 15 years was engaged in foreign travel. In 1898 he explored the oasis of Siwa and in 1900 traveled in the Sudan. His publications include 'Development of Africa' (1890); Report to the Paris Geographical International Congress (1898); 'From Sphinx to Oracle' (1899); 'The Expansion of Egypt' (1899), etc.

**WHITE**, **Bouck**, Socialist writer and orator: b. Middleburg, N. Y., 1874. He completed the Harvard course at 18 and was graduated from the Union Theological Seminary in 1902. In following years he held several charges and from 1908 to 1913 was resident pastor of Trinity House, Brooklyn. Always extremely socialistic in his views, he aroused antagonism and was relieved of his charge. He at once organized the church of the Social Revolution, in Manhattan, N. Y. The following year he was arrested for interfering with a church service and sentenced to six months for disorderly conduct. In 1916 he trampled on an American flag and was again sent to prison for treasonous utterances. He is a writer of considerable force and has produced 'Quo Vaditis' (1903); 'The Mixing' (1913); 'The Carpenter and the Rich Man' (1911); 'Letters from Prison' (1915).

**WHITE**, **Charles Abiathar**, American geologist: b. North Dighton, Mass., 26 Jan. 1836; d. 1910. He was State geologist of Iowa in 1866-70, occupied the chair of natural history at the Iowa State University in 1867-73, and in 1873-75 held that chair at Bowdoin College, Maine. In 1874-92 he was engaged as geologist and palæontologist on different United States government surveys, and after 1876 was connected honorably with the Smithsonian Institution and the United States National Museum, where he was associate in palæontology. He has published 'Report on the Geological Survey of Iowa' (1870); 'Report on Invertebrate Fossils and Surveys West of the 100th Meridian' (1875); 'Review of the Fossil Ostreids of North America' (1883); 'The Relation of Biology to Geological Investigation' (1894), etc. A complete list of his writings, including 211 titles (1860-85), was catalogued by J. B. Marcott (1885).

**WHITE**, **David**, American geologist: b. Palmyra, N. Y., 1 July 1862. He was graduated at Cornell University in 1886; has been with United States Geological Survey since 1886 and is at present chief geologist of that bureau. His speciality is paleozoic paleobotany and he has served as associate curator of that branch in United States National Museum since 1900.

member of the National Academy of Science, Fellow of the Geological Society of America, and of the American Association for the Advancement of Science, etc. He has published: 'Fossil Flora of Carboniferous of South-Missouri'; 'Flora of Lower Coal Measures of Missouri'; 'Effect of Oxygen in the Fossil Plants of the Group Cycadoides of the Fossil Flora of West Virginia'; 'Fossil Flora of the Appalachian Coal Field'; 'Origin of the Fossil Flora of Coal Measures of Missouri' and many papers in government and scientific periodicals.

**WHITE, Edward Douglass**, American jurist: b. parish of Lafourche, La., 3 Nov. 1845. Educated at Mount Saint Mary's College, Maryland, and at the Jesuit College in New Orleans during the Civil War served in the Confederate army. He subsequently studied law and was admitted to the Louisiana bar.

State senator in 1874; associate justice of the Supreme Court in Louisiana in 1878, and United States senator in 1889-94. While still a member of the Senate he was appointed an associate justice of the United States Supreme Court on 12 Dec. 1910 he was created chief justice.

His opinions on trust cases and the law added much to his reputation. He held his position to his ability, being addressed first by President Cleveland and later by President Taft.

**WHITE, Edwin**, American naval officer: b. 1843; d. Brooklyn, N. Y., 23 Dec. 1905. He was graduated from the United States Naval Academy in 1864; was promoted lieutenant in 1869; commander in 1886; duty at the Naval Academy as commander of cadets in 1895-98; received rank as rear-admiral in 1898 and was assigned to command the USS *Adelphia*, flagship at the Pacific station. Returned from Samoa in 1899 with broken health and was retired from active duty with the rank of rear-admiral.

**WHITE, Eliza Orne**, American author: b. N. H., 2 Aug. 1856. Her publications include: 'Miss Brooks' (1890); 'Winterborn' (1892); 'When Molly Was Six' (1894); 'Coming of Theodora' (1895); 'A Little Long Ago' (1896); 'A Browning Poem and Other Stories' (1897); 'A Lovelace' (1898); 'Edna and Her Brothers' (1900); 'John Forsyth's Aunts' (1901); 'The Enchanted Garden' (1909); 'The Enchanted Garden' (1911).

**WHITE, Frank**, American politician: b. Danvers, Ill., 12 Dec. 1856. He was educated in civil engineering from the University of Illinois in 1880. A few years later he moved to North Dakota, where he became prominent in politics as a Republican; in 1891-93 a member of the lower house of State of North Dakota, and in 1893-99 a member of the State Senate. During the Spanish-American War he was in the army, was major of the First North Dakota regiment and served in the Philippines. He was elected governor of the State of North Dakota for four years.

**WHITE, SIR George Stuart**, English soldier: b. 6 July 1835; d. Chelsea, 26 June 1912. Educated at Sandhurst, entered the army in 1853, served in the Indian mutiny and

the Afghan War, became military secretary to the viceroy of India, and in 1881 lieutenant-colonel of the Gordon Highlanders. His subsequent promotions were colonel (1885), lieutenant-general (1895), major-general and field marshal. From 1893 to 1898 he was commander-in-chief of the forces in India, in 1898-99 quartermaster-general to the forces, and in 1899-1900 was general on staff to command troops at Ladysmith. He defended Ladysmith 118 days (2 Nov. 1899-18 Feb. 1900) against the Boers, being relieved by Lord Dundonald after a disastrous siege. In 1900 he was made governor of Gibraltar, where he remained four years, during which period he was made field marshal. In 1905 he received the Order of Merit, and was transferred to the governorship of Chelsea Hospital. See **SOUTH AFRICAN WAR**.

**WHITE, Gilbert**, English naturalist: b. Selborne, Hampshire, 18 July 1720; d. there, 26 June 1793. He was graduated from Oriel College, Oxford, in 1743, and having taken deacon's orders in 1747, acted as curate to an uncle at Swarraton. After being ordained priest he was for a short period in 1751 curate to the vicar of Selborne. Appointed dean of his college in 1752 he soon after became curate of Durley, Hampshire. He failed to secure the provostship of Oriel in 1757, but in the same year obtained the vicarage of Morton Pinkney, in Northamptonshire, which was in the gift of his college. He never resided on his Northamptonshire living, but throughout his whole life remained closely associated with the Hampshire parish which he has made famous. About 1758 he gave up the Durley curacy for that of Faringdon, near to his home, though for a time he acted as curate of West Deane, Wiltshire. White's great English classic 'The Natural History and Antiquities of Selborne,' the only work of the kind in the language to attain that rank, was published at the end of 1788, with the date 1789 on the title-page. It consists of letters to his two friends, Thomas Pennant, author of the 'British Zoology' and Daines Barrington, who devised the form of 'Naturalist's Journal' which White kept from 1767, when he discontinued the 'Garden Kalendar' begun in 1751. In the preparation of the part on antiquities, compiled only when he had been induced to publish, he was greatly assisted by Richard Chandler, the classical antiquary and traveler. His 'Natural History of Selborne' has won the enthusiastic admiration of men of widely different tastes, and has gone through a very large number of editions. Professor Newton says that such was White's keenness of observation, his undoubted errors are scarce worthy of notice. In America, where most of the plants and animals mentioned are, save to a few experts, known only by name, the popularity of the work has been great. The most important editions after the first are the following: the so-called Markwick's or Aikin's (1802), including 'The Naturalist's Calendar,' which Dr. Aikin had compiled from White's papers and published in 1795, but excluding the 'Antiquities'; the 1813 octavo, including his poems for the first time; Mitford's (1813); Rennie's (1833); Bennett's (1837), based upon the preceding; Jardine and Jesse's (1851);

Jardine's (1853); Harting's (1875), one of the best, based upon Bennett's; Buckland's (1875), with a chapter on the 'Antiquities' by the Earl of Selborne; Bell's (1877), which superseded all previous ones, and may still be regarded as the best (see BELL, THOMAS); Grant Allen's (1889), without the 'Antiquities'; and Bowdler Sharpe's (1900-01), including the 'Antiquities' and the 'Garden Kalendar.' There is a bibliography (1897) by E. A. Martin. Consult Jesse, 'Gleanings in Natural History,' 2d series (1834); Gordon, 'Gilbert White in Sussex' (1893); and Shelley's 'Gilbert White and Selborne' (New York 1906).

**WHITE, Henry,** American diplomat: b. Baltimore, Md., 29 March 1850. He was privately educated in the United States and in Europe, and entered the United States diplomatic service. He was secretary of the United States Legation at Vienna in 1883-84; was second secretary of the Embassy at London in 1884-86, and afterward secretary until 1893, when his connection with the diplomatic service was interrupted by the Cleveland administration in 1893. In the meantime he had frequently acted as chargé d'affaires, and in 1886 he was special American representative at the International Conference which abolished sugar bounties. He was reappointed secretary of the Embassy at London by President McKinley in 1897, and occupied that office until he was appointed Ambassador to Italy by President Roosevelt in 1905. He was Ambassador to France in 1907-09, and in 1910 was sent as special Ambassador to Chile. He headed the American delegation at the Algeciras Conference concerning Moroccan affairs in 1906; and in 1917 was appointed manager of the Potomac division of the Red Cross. On 30 Nov. 1918 he was appointed a member of the United States delegation to the Paris Peace Conference, where he served on the Waterways Commission, and was chairman of the subcommittee of the Commission of the Internationalization of Ports, Waterways and Railroads.

**WHITE, Henry Kirke,** English poet: b. Nottingham, 21 March 1785; d. Cambridge, 19 Oct. 1806. The son of a butcher, he was apprenticed to a stocking weaver, and later to an attorney, in whose office he devoted his spare time to the study of Latin and Greek. At 14 he wrote verse which was published in different magazines, and in 1803 published 'Clifton Grove, a Sketch in Verse, with Other Poems,' a venture which won for him the attention and friendship of Southey and other literary men. He obtained a sizarship at Saint John's College, Cambridge, in 1804, and entered upon his studies with such close application that his health broke under the strain, resulting in his death from consumption. After his death his manuscripts were placed in charge of Southey, who edited his poems, letters, etc., and published them under the title 'Remains, etc., with an Account of his Life' (1807). He will be longest remembered by his hymn beginning

"When marshalled on the nightly plain  
The glittering host bestud the sky."

**WHITE, Henry Seely,** American mathematician: b. Cazenovia, N. Y., 20 May 1861. He was graduated at Wesleyan University in 1882,

and took his Ph.D. at Göttingen in 1891. He was professor of pure mathematics at Northwestern University in 1894-1905, also serving as secretary of the faculty there in 1903-05; and since 1905 he has been professor of mathematics at Vassar College. He was also president of Vassar Brothers Institution in 1911-13, and has occupied that position since 1916. He was president of the American Mathematical Society in 1907-08; and was elected to the National Academy of Sciences in 1915. He was associate editor of the *Transactions* of the American Mathematical Society in 1902-06, and its editor in 1907-13. He has specialized on the geometry of curves and surfaces and on the theory of variants.

**WHITE, Hervey,** American author: b. New London, Iowa, 26 Nov. 1866. He was graduated from Harvard in 1894, and was reference librarian in the John Crerar Library 1896-99. He has published 'D' (1899); 'Quicksand' (1900); 'When Love is Not Created, and Other Stories' (1900); 'N' and the Fairies' (1902); 'In an Old Man's Garden' (1910); 'The Adventures of You Maverick' (1911).

**WHITE, Horace,** American editor: b. Cobleskill, N. H., 1834; d. New York City, Sept. 1916. He was graduated from Beloit College, Wisconsin, and from Brown University. Entering upon the career of journalism, he came city editor of the *Chicago Evening Journal*, correspondent of the *Associated Press* and assistant secretary of the National Kansas Committee. As correspondent for the *Chicago Tribune*, he accompanied Abraham Lincoln on his political campaign against Douglas. He headed a syndicate for the publication of *Civil War* news during 1864, and from 1865-74 was editor-in-chief of the *Chicago Tribune*. Leaving this post, he went to New York in the capacity of treasurer of the Oregon Railway and Navigation Company. He was one of the founders of the *New York Evening Post*, acting first as head of the company, and later (1899-1903) as editor-in-chief, retiring as editor emeritus. In 1909 he was appointed by Governor Hughes to serve on the New York State Commission on Speculation in Securities and Commodities. As an author he published several noteworthy works, including 'Money and Banking' (1895); 'Life of Lyman Trumbull' (1913), and edited several French and Italian works on finance.

**WHITE, Horatio Stevens,** American educator: b. Syracuse, N. Y., 23 April 1852. He was graduated at Harvard University in 1873, later studied in Europe, and was admitted to the bar of New York in 1878. He was assistant professor of Greek and Latin at Cornell University in 1876-78, later was assistant in German, and was appointed professor of German there in 1891. Since 1902 he has occupied the chair of German at Harvard University. He edited 'Selections from Lessing's Prose' (1888); 'Selections for German Prose Composition' (1891); 'Deutsch Volklieder' (1892); Appleton's 'Twentieth Century Series of German Classics' (1901-05); Fiske's 'Chess Tales and Chess Miscellanies' (1912), etc.

**WHITE, Hugh Lawson,** American jurist and legislator: b. Iredell County, N. C., 30 Oct.

**White, John**, American lawyer and politician: b. Knoxville, Tenn., 10 April 1840. He was a volunteer against the Cherokees in 1861 and began practice at Knoxville. He was judge of the Supreme Court of Tennessee, 1861-67, and 1869-75, became State district attorney in 1867, was elected to the State senate, was president of the Bank of Tennessee in 1815-27, senator in 1817-25, United States congressman in 1821-24 for the adjustment of claims against Spain, and in 1825 was elected to the United States Senate to succeed General Jackson. He was opposed to the making of improvements by the Federal government in the movement which resulted in the establishment of the National Bank. He was an earnest advocate of the removal of the western part of the Mississippi, and by his support of the bill to limit executive patronage he incurred the enmity of Jackson. In 1835 he was elected to the Presidency, his electors were from Georgia and Tennessee, and he received a majority in the electoral college. He became a Whig in 1838, and in 1839 resigned in the Senate because of his unwillingness to vote for the Sub-Treasury Bill, as he was instructed to do by the Tennessee legislature. Consult Scott, Nancy N., 'Memoir of John White' (1856).

**White, Israel Charles**, American geologist: b. Monongalia County, W. Va., 1 Nov. 1849. He was graduated at West Virginia University in 1872. He was assistant geologist of the United States Geological Survey in 1873-75, and in 1877-92 he was professor of geology at West Virginia University. He represented the State in 1892 in order to develop a large petroleum business, and he has been State geologist of West Virginia. He is an authority on coal, petroleum, and natural gas, and with Edward Orton he was the developer of the anticlinal theory of oil migration. The West Virginia 'Geological Survey' contains many of his reports.

**White, James**, Canadian geographer: b. London, Ontario, 3 Feb. 1863. He was graduated at the Royal Military College, Kingston, Ontario. He was a government surveyor in the Province of Quebec and Ontario in 1884-86, geographer and chief draughtsman of the Canadian Geological Survey in 1894-99; chief geographer of the Department of the Interior in 1899-1912. He was appointed director of the Royal Conservation Commission in 1909, and became its assistant chairman and deputy head in 1913. Since 1917 he has been chairman of the advisory board of the Canadian Life Protection. He has published a number of papers on Canada, and several large scale maps. He is author of 'Altitude in Canada' (1906); 'Maps and Map Making in Canada' (1906); 'Atlas of Canada' (1906); 'Oregon and its Juan Boundaries' (1908); 'Derivation of Place Names in Canada' (1912); 'A Study of Altitudes' (1903; 1916), etc.

**White, James William**, American surgeon: b. Philadelphia, Pa., 2 Nov. 1850; d. Philadelphia, Pa., April 1916. He was graduated M.D. at the University of Pennsylvania in 1874 and in 1871-72 served on Professor Henshaw's staff in the Hassler Expedition to the

West Indies, the coasts of South America and the Straits of Magellan. He then engaged in practice at Philadelphia, held several hospital charges and was successively professor of genito-urine surgery, of clinical surgery and of anatomy. He was professor of surgery at the University of Pennsylvania until he retired, becoming professor emeritus. He was attached to the American Ambulance Hospital at Neuilly, France, in 1915. Aberdeen University conferred the degree LL.D. on him in 1906. He left a bequest of \$400,000 to the University of Pennsylvania. He was co-author of 'American Text-Book of Surgery' (1896); 'Genito-Urinal Surgery' (1897); 'Human Anatomy' (1906), and author of 'Text-Book of the War for Americans' (1915).

**White, John Blake**, American artist and author: b. Eutaw Springs, S. C., 2 Sept. 1781; d. Charleston, S. C., 24 Aug. 1859. He studied under Benjamin West in London in 1800-04. Returning to the United States, he established himself in Boston, but on account of the lack of practice went to Charleston, S. C., and became a lawyer, was successful in that profession, and was several times a member of the South Carolina legislature. His best-known picture, 'The Unfurling of the United States Flag in the City of Mexico,' was destroyed during the Civil War. His other paintings include 'Battle of Eutaw Springs' (1804); 'Battle of Fort Moultrie' (1806); 'Battle of New Orleans'; 'Mrs. Motte Presenting the Arrows'; and 'Marion Inviting the British Officer to Dinner' (1836). He also wrote the dramas 'Foscari, or the Venetian Exile' (1805); 'Mysteries of the Castle' (1806); 'Modern Honor' (1812); 'Triumph of Liberty, or Louisiana Preserved' (1819), and 'Intemperance' (1839).

**White, John Campbell**, American religious worker and university president; brother of Wilbert W. White (q.v.): b. Wooster, Ohio, 31 March 1870. He was graduated at the University of Wooster in 1890. In 1890-91 he was national college secretary of the Young Men's Christian Association, and he was traveling secretary of the Student Volunteer Movement in 1891-92. He was general secretary of the Y. M. C. A. at Calcutta, India, in 1893-1903, and served as secretary of the ways and means committee of the United Presbyterian Church in 1903-06. He was secretary of the Laymen's Missionary Movement in 1907-15, and has since been president of the University of Wooster. He is author of 'Missions and Leadership' (1915).

**White, John Hanson**, American Protestant Episcopal bishop: b. Cincinnati, Ohio, 10 March 1849. He was graduated from Kenyon College in 1872, and Berkeley Divinity School, Middletown, Conn., in 1875. He was ordained priest in 1876, was rector of Grace Church, Old Saybrook, Conn., 1878-81; of Christ Church, Joliet, Ill., 1881-89; Saint John's Church, Saint Paul, 1889-91, and warden of Sealbury Divinity School, Fairbault, Minn., 1891-95. In the last-named year he was consecrated bishop of Indiana and on the division of the diocese in 1899 chose the northern portion with the title of bishop of Michigan City.

**White, Joseph Blanco**, English clergyman and author: b. Seville, Spain, 11 July 1775;

d. Liverpool, 30 May 1841. After study in Seville University, he was ordained sub-deacon (1796) and priest (1800) in the Roman Catholic Church, in 1802 was appointed to a chaplaincy in the Chapel Royal of Saint Ferdinand at Seville, but having abandoned his belief in Christianity, withdrew from the priesthood, and went to England in 1810. There he became editor of *Español*, a monthly periodical, circulated in Spain (partly by the English government) in aid of the national cause; in 1812 again became a Christian; and in 1814 qualified as an English clergyman. He began contributing in 1820 to the *New Monthly*, edited by Thomas Campbell (q.v.), and in 1825 published 'Evidences against Catholicism.' In 1826 he settled at Oxford as a member of Oriel, and there Newman, Pusey and other leaders of the Oxford movement learned much from him respecting Catholic theology. He finally became an acknowledged Unitarian, and from 1835 lived at Liverpool, doing some desultory literary work. Many of his books had a real interest in their time; but he is best known to literature by his sonnet 'Night and Death,' which Coleridge, in a letter of 1827, declared to be the finest in the English language. Among his further publications are 'Letters from Spain by Don Leucadio Doblado' (1822); 'Second Travels of an Irish Gentleman in Search of a Religion' (1833); in answer to Thomas Moore's 'Travels,' and 'Observations on Heresy and Orthodoxy' (1835).

**WHITE, Octavius Augustus**, American physician: b. Charleston, S. C., 8 Feb. 1826; d. New York, 25 May 1903. He was graduated from the College of Charleston in 1846 and from the South Carolina Medical College in 1848, he practised with success until the outbreak of the Civil War, and he was made surgeon in the Confederate army. He became an expert on yellow fever, during the war he was sent within the Union lines at Goldsborough, N. C., for medical services connected with the fever, and wrote much on the subject, as well as on general topics of medicine and surgery. Several professional inventions are to be credited to him.

**WHITE, Percy**, English novelist: b. London 1852. He taught English literature and language in a French college for some years, entered journalism in 1880 and for 10 years edited *Public Opinion*. He has published several brilliant novels, strongly satirical in character, among them being 'Mr. Bailey-Martin' (1893); 'Andria' (1896); 'A Millionaire's Daughter' (1898); 'The Heart of the Dancer' (1900); 'The New Christians' (1902).

**WHITE, Peregrine**, the first child born in New England of English parents: b. on board the *Mayflower*, in the harbor of Cape Cod, 20 Nov. 1620; d. Marshfield, Mass., 22 July 1704. He was the son of William and Susanna White, and on account of his birth received 200 acres of land from the General Court. He filled various civil and military offices, and "was vigorous and of a comely aspect to the last." His father died during the colonists' first winter at Plymouth, and the marriage of his mother to Gov. Edward Winslow was the first wedding in New England.

**WHITE, Richard Grant**, American author and critic: b. New York, 22 May 1821; d. there, 8 April 1885. He was graduated from the New York University in 1839, studied medicine and then law, and became a contributor of musical, art and dramatic critiques to the *New York Courier and Enquirer*. From 1854 to 1859 he was an editor of this journal; and of the *World*, 1860-61. His 'Yankee Letters,' contributed in 1853-67 to the *London Spectator*, were interesting narratives of contemporary events and of considerable service to the national cause. In 1861-78 he was chief clerk of the United States revenue marine bureau for the district of New York. White was particularly known as a Shakespearean scholar. He contributed articles on Shakespeare to *Putnam's Magazine* in 1853, in 1854 published 'Shakespeare's Scholar,' and in 1857-63 a critical edition of the poet's works. Other volumes on this general subject were, 'Essay on the Authorship of the Three Parts of Henry The Sixth' (1859); 'Memoirs of William Shakespeare with an Essay toward the Expression of his Genius' (1865), and the posthumous 'Study in Shakespeare' (1885). White's 'Riverside edition of Shakespeare' (1883) was one of the most popular prepared by an American. He was also one of the leading American critics of his time, dogmatic at times and over-hasty in generalization, but vigorous, acute and frequently brilliant. Philological studies were represented by his 'Words and their Uses: A Study of the English Language' (1870; rev. ed., 1872), and 'Every-Day English' (1881). The most widely circulated of his writings was the anonymous satire 'The New Gospel of Peace' (1863-66). He also wrote a novel 'The rate of Mansfield Humphreys' (1884), and edited 'Illustrated Record of the New York Exhibition of the Industry of All Nations' (1854), and 'Poetry, Lyrical, Narrative, and Satirical of the Civil War' (1866). His scholarship was considerable, his style readable and often marked by satire, and his authority in his day decided. An interesting article regarding him by F. P. Church appeared in the *Atlantic* for March 1891, Vol. 67.

**WHITE, Stanford**, American architect: b. New York, 9 Nov. 1853; d. New York, 25 June 1906. He was the son of Richard Grant White (q.v.) and was graduated from the University of New York and received his professional training under Charles D. Gambrill and H. H. Richardson, and was the chief assistant of the latter in the construction of Trinity Church, Boston. In 1881 he became a member of the firm of McKim, Mead and White. He was the designer of Madison Square Garden, the Washington Arch, the Tiffany apartments, Columbia University Library, the Century and Metropolitan Club buildings, and other important structures. He was killed in the Madison Square Garden, New York, by Harry K. Thaw.

**WHITE, Stewart Edward**, American novelist: b. Grand Rapids, Mich., 12 March 1873. He was graduated from the University of Michigan in 1895 and studied law at the Columbia Law School (1896-97). He has published stories of Western life, including 'The Westerners' (1901); 'The Claim Jumpers' (1901); 'The Blazed Trail' (1902); 'Con-

(1903); 'The Forest' (1903); (1907); 'The Cabin' (1910); 'Footprints' (1912); 'Gold discovered Country' (1915).

**Wilbert Webster**, American re- and educator, brother of J. C. b. Ashland, Ohio, 16 Jan. 1863. ed at the University of Wooster a Theological Seminary in 1885, h.D., at Yale University in 1891. was professor of Hebrew and Literature at Xenia Theological after serving as a teacher at ble Institute, Chicago, in 1895- l in religious work in England 1897-1900. In 1900 he became the Bible Teachers' Training York. He is editor of the w and is author of 'Thirty emiah' (1895); 'Thirty Studies' (1897); 'Studies in Old Testa- rs' (1900; 2d ed., 1904); 'Thirty Gospel by Matthew' (1903), etc.

**William**, American Protestant op: b. Philadelphia, Pa., 4 April 17 July 1836. He was graduated : of Philadelphia in 1765, come- ological studies in 1770, and and to obtain holy orders, was he diaconate by the bishop of '0, and to the priesthood by the wrich in 1772. Returning to e became assistant minister and or of Christ Church and Saint 1, being at one period the only gyman in Philadelphia, and in ain to Congress. The degree of t honorary degree of the Uni- nsylvania, was conferred on him eting which issued the summons on preparatory to organizing the iscopal Church, was held at his and he presided over the First ention in 1789. In 1786 he was of Pennsylvania and was conse- beth palace, England, 1787. He rs of the Protestant Episcopal ); 'Lectures on the Catechism' onsult 'Memoir,' by Bird Wil- cConnell, 'History of the Amer- Church' (1890).

**William Alanson**, American d alienist: b. Brooklyn, N. Y., He studied at Cornell University was graduated M.D. at the Long Hospital in 1891. He was as- in at the New York State Hos- Insane at Binghamton in 1892- e 1903 he has been superintend- Elizabeth's Hospital for the In- ngton, D. C. He has also held nervous and mental diseases at iversity since 1903 and at George iversity since 1904, as well as e United States Naval and Army l. He has collaborated with Dr. iffe (q.v.) in preparing different es. Author of 'Mental Mechan- 'Outlines of Psychiatry' (5th 15), etc.

**William Allen**, American author: n., 1868. He was educated at the

University of Kansas and in 1890 became editor of the *Eldorado Daily Republican*. He after- ward was engaged on the editorial staffs of the *Kansas City Journal* and of the *Star*, and in 1894 purchased the *Emporia Gazette*. His edi- torial, 'What's the Matter with Kansas?' pub- lished in that paper in August 1896, was read and reprinted throughout the country. He has published 'The Real Issue' (1896); 'The Court of Boyville' (1899); 'Stratagems and Spoils' (1901); 'A Certain Rich Man' (1909); 'The Old Order Changeth' (1910); 'God's Puppets' (1916); 'In the Heart of a Fool' (1918); 'The Martial Adventures of Henry and Me' (1918), etc.

**WHITE, Sir William Henry**, English naval constructor: b. Devonport, 2 Feb. 1845; d. 1913. He was educated at the Royal School of Naval Architecture, served in the construc- tive department of the Admiralty, 1867-83, be- coming chief constructor, and from 1870 to 1881 was professor of naval architecture at the Royal School of Naval Architecture and at the Royal Naval College. In 1883-85 he organized and directed the warship building department of Armstrong and Company, Newcastle. From 1885 to 1902 he was director of naval construc- tion and assistant comptroller of the navy, and during that period was the responsible designer of all British ships of war. Upon his resigna- tion, due to failing health, he received from Parliament a special money grant in recogni- tion of his services to the navy. He has pub- lished 'A Manual of Naval Architecture'; 'Architecture and Public Buildings'; 'A Treatise on Shipbuilding,' and numerous pro- fessional papers.

**WHITE, Sir William Thomas**, Canadian statesman: b. Bronte, Ontario, 13 Nov. 1866. He was graduated at Toronto University in 1895 and was called to the bar of Ontario in 1899. He was for some years engaged in newspaper work on the staff of the *Toronto Evening Telegram*, and later was connected with the assessment department of the Toronto municipal government. He became prominent in financial circles and was president of the National Trust Company in 1900-11. He was a determined opponent of the Reciprocity Treaty between Canada and the United States, and although a Liberal in politics was instru- mental in defeating the Laurier Ministry. He has been Minister of Finance in the Conserva- tive Cabinet of Sir Robert L. Borden since October 1911. He was knighted in 1916.

**WHITE ANTS.** See TERMITES.

**WHITE BASS.** See BASS.

**WHITE BOOK**, a government publication in Germany and Portugal, corresponding to the British Blue Book and the Yellow Book of France. See BLUE BOOKS.

**WHITE BOYS**, an illegal association formed in Ireland in 1760, composed of starv- ing day-laborers, evicted farmers and others in a like condition, who used to assemble at nights to destroy the property of landlords or their agents, the Protestant clergy, the tithe collectors or any others that had made themselves ob- noxious in the locality. In many cases they did not confine their acts of aggression merely to plunder and destruction, but even went the length of murder.

**WHITE BRETHREN** a sect which caused a commotion in Europe about the beginning of the 15th century. A priest whose origin is unknown, his nationality being variously alleged as Spanish, French and Scotch, made his appearance in Lombardy, and said that he was the prophet Elias, and had come back from heaven to give notice of the coming destruction of the world. He had thousands of followers, who were arrayed in white, and carried large crucifixes, as they marched from the Ligurian Alps into central Italy. Pope Boniface IX caused him to be apprehended, and he was burned as an impostor. The White Brethren then dispersed.

**WHITE CAMELIA**, The Knights of the, formed in May 1867 at New Orleans, was the largest of the revolutionary orders called into existence by the misgovernment of Reconstruction. Its principal strength was in the Gulf States, farther south than the notorious Ku Klux Klan (q.v.). The organization was as follows: A supreme council for the United States; a grand council in each State; a central council in each congressional district and councils in each county. Each council was divided into circles and groups. The officers of the council were known as commander, lieutenant-commander, etc.; the members were called "brothers." The objects of the order were, to nullify radical legislation, to reduce the influence of the blacks in politics, to prevent amalgamation of the races and to defend the white race against radical encroachment. The members swore to vote for no black for office, to observe always a marked distinction between the races, to maintain the social and political superiority of the white race, at the same time protecting the blacks in the privileges rightfully theirs. The constitution forbade the indorsement of any political party by the order. Each member was free to vote as he pleased, subject to his oath always to oppose negroes for office, or those favorable to negro political rights. The order sometimes operated also as a body of regulators using such methods as were usually attributed to the Ku Klux Klan, but the membership was of a higher order. The discipline was good and the effect of its operations was to control the lawless negroes, intimidate and drive from the country the carpet-baggers and to secure again to the whites control of the State and county governments. These objects being accomplished, the order gradually disbanded. Its secrets were well kept and not until recent years was anything definite known of the order. The White Brotherhood and the White League were closely related orders that existed in the same territory a few years after the White Camelia had disintegrated. Consult Brown, 'Lower South American History' (1902); 'Constitution and Ritual of the Knights of the White Camelia,' in West Virginia University Documents relating to Reconstruction, Nos. 1 and 2.

**WHITE CAPS**, in American history, the lawless bands in southern Indiana, who, from 1880, undertook the regulation of the manners and morals of that section. During the Civil War, the Knights of the Golden Circle (q.v.) flourished in the same parts. The White Caps dressed differently in different parts of the

country which they terrorized. Where they were regularly organized and did the most mischief they generally had nearly a full uniform or regalia. They wore white paper foolscaps, with paper masks, and coats of coffee sackings. To make the coats they merely cut arm or sleeve holes in the sides of coffee sacks close to the bottoms and holes in the bottoms to put their heads through.

**WHITE CATTLE** (of Chillingham), certain cattle preserved in a semi-wild state in Chillingham Park, England. They are pure white, except the muzzle, which is black, and the horns which are tipped with black. The white color on the body, however, is artificially produced, the owner causing all spotted calves to be killed. They are now generally believed to be the descendants of the mountain bull or urus (see Ox), which was wild in Gaul at the time of Cæsar's invasion, and the stock whence modern breeds of domestic English cattle have been partly derived. Dawkins, however, considers them the last surviving representatives of a still more primitive race, the gigantic ox known by its remains in caves to have occupied Great Britain in the Pleistocene Period. He considers them much modified in every respect by their small range and their contact with man.

**WHITE CLOVER, OAK PINE.** See CLOVER; OAK; PINE.

**WHITE COLORS**, in painting, white pigment or white lead. Baryta yields several commercial varieties of white color, largely used for adulterating white lead. The substances used are heavy spar, the native sulphate, and witherite, the native carbonate, of baryta. An artificial sulphate of baryta is also used in permanent white. Zinc white or Chinese white is a hydrated oxide of zinc and pearl white is yielded by the nitrate of bismuth. A fine chalk yields Spanish white, and whiting is ordinary ground chalk. Quicklime is a sanitary white for external walls, etc.

**WHITE CROSS**, a self-supporting American organization which had a large membership throughout the Union, having for its motto, "Truth, Charity and Philanthropy," and for its emblem cross bandages of white on a field of red. It was founded in 1898 by Mrs. Jane Creighton of Portland, Ore., and its object was the care of wounded and sick American soldiers and sailors, and aid to the widows and orphans of those who had fallen in battle, or died of disease or accident.

**WHITE CROSS SOCIETY**, an association founded in England, in 1883, by the bishop of Durham, and introduced in the United States in that year by the Rev. B. F. De Costa, rector of the Protestant Episcopal Church of Saint John the Evangelist, New York, who became a Roman Catholic in 1899. The objects of the society are "to urge upon men the obligation of personal purity; to raise the tone of public opinion upon the subject of morality; to secure proper legislation in connection with morality." Those who become members of the society promise "by the help of God" to treat all women with respect and endeavor to protect them from wrong and degradation; to endeavor to put down all indecent language and coarse jests; to maintain the law of purity as equally

and women; to endeavor to principles and try to uplift and to use every possible the command, "Keep thyself society seeks to forward its ob- ill presentation of those spirit- form distinguishing character- stianity and demonstrate its lity to every form of impurity." been established also in Canada.

**DECORATIONS.**  
**LEPHANT,** an elephant af- inism. Such animals, always y esteemed by some Eastern are considered sacred in Siam, d has become a national symbol, called "the land of the white one of the highest decorations rulers is that of the Order of ant. A specimen purchased by arnum from King Theebaw, of ough to the United States in seven feet and a half high and front of trunk, fore feet and vere of a light ash color. Fig- ent which does one much more , or more generally any nominal has this effect. It is reported d times the ruler of Siam de- y one, he made him a present ant. The sacred elephant has ppetite, and, being sacred, it e to let it die, so that the gift d ruin on the recipient.

**YES,** one of the numerous ous birds of the New Zealand ight-birds locally, because they upon the plant-lice which tor- ants and orchard trees. They genus *Zosterops*, which is vari- by ornithologists, but seems elated to the titmice. Other tered elsewhere throughout the pics. All are neatly but not l have in most cases a con- of white feathers around the pretty nests. The genus is in- r, from the fact that many of confined to small islands, ap- ng examples of the effect of

**FATHER,** a symbol of coward- oduced in the days when cock- vogue. As a thoroughbred game te feathers, a white feather was e bird was not game.

**Y,** a minute insect of the fam- closely allied to the aphids and nest the leaves of plants, usu- r side, and are pests in green- GREENHOUSE INSECTS). They a whitish mealy secretion, and o secrete wax. The group is and does not do much harm to trees, except that one species ) has been prevalent in Florida ince about 1890. The evil they nly from their sucking the nu- the plants, but from the spread

of smut-fungus which is promoted by their presence. Consult Howard, 'The Insect-book' (New York 1901).

**WHITE FRIARS,** a name formerly given to the friars of Our Lady of Mount Carmel, because they wore a white scapular and cloak over their brown habit. See **CARMELITES**.

**WHITE GOAT.** See **ROCKY MOUNTAIN**

**GOAT.**  
**WHITE HATS,** a badge of the Demo- cratic party in Flanders in the 14th century. White hats were used in England to denote radical proclivities, because Orator Hunt (1773-1835), the great demagogue, during the Wellington and Peel administration, used to wear a white hat.

**WHITE HELLEBORE,** a liliaceous plant of the genus *Veratrum*, a source of insect-poi- son, the principle of which is the alkaloid vera- trin. See also **HELLEBORE**.

**WHITE HOUSE,** the official residence of the President of the United States, in Wash- ington, D. C. The name arose from the fact that the building is constructed of freestone and painted white. It is 170 feet long, 86 feet deep and two stories in height. It has an Ionic por- tico, the main entrance faces north. Reception rooms are on the first floor and the private apartments of the President are on the second floor. Among the reception rooms are the Blue Room used for diplomatic functions, the East Room used for public receptions, and the Red and Green rooms. The original official resi- dence for the President was begun in 1792; it was first occupied by Adams, in 1800. In 1814 it was burned by the British and four years later was rebuilt. In 1903 executive offices con- nected with the main building were built on the grounds. President Harrison and McKin- ley used for the official name, "Executive Mansion"; President Roosevelt returned to the old name, White House.

**WHITE LADY,** an apparition which fig- ures in the legends and traditions of various countries, as presenting herself to give warning of death and other momentous events in royal and titled households. The White Lady is sup- posed to be an ancestress of the family she vis- its, and the association of such a legend with a family name is regarded as a guarantee of noble and ancient lineage. The one-time imperial house of Hohenzollern had its White Lady, and Hampton Court, England, is said to be invaded at times by a supernatural visitor, although there seems to be some doubt whether it is a White Lady or the ghost of Henry VIII. The earliest historical instance of the apparition is recorded as having occurred in the 15th century and is celebrated under the name of Bertha of Rosenberg, in Bohemia. Similar appearances are said to have been witnessed in the Schloss at Berlin, one as recent as 1879.

**WHITE LEAD,** a white pigment very largely used in painting. Many processes have been devised for its manufacture. The old Dutch method was to expose sheet lead in coils, placed in earthenware jars partly filled with vinegar, to the combined action of air, moist- ure and carbonic acid gas. This was done by immersing the jars with their contents in de- composing horse manure which furnished the heat and carbonic acid gas necessary for the

process. The English process, which is the one by which most of the white lead is made, differs from the Dutch process by the use of fermenting tan bark instead of manure. The pots containing the lead and dilute acetic acid or vinegar are piled in rows in the so-called stacks and surrounded with the fermenting tan bark. After about three months the lead is removed and purified. The process is slow and the methods of purification dangerous to the workmen, but the resulting white lead is of the best quality. In the French method a solution of basic lead acetate is first prepared by the action of an impure acetic acid on litharge or lead oxide. Carbonic acid gas is then passed through this solution and the white lead precipitated. White lead is also produced electrolytically, by employing a solution of sodium-nitrate, preferably in a cell of wood and a porous diaphragm. The anode is of lead and the cathode of copper. When the current is turned on, nitric acid appears at the anode as lead nitrate and from the cathode appears caustic soda. The lead hydroxide obtained is later treated with sodium bicarbonate to secure the carbonate of lead. White lead is subject to frequent adulteration. It may be tested for purity by making a solution of the powder in acetic acid, which should take up all the lead and leave the adulterant. White lead is a basic carbonate of lead of somewhat variable composition. That formed by the Dutch and English processes may be represented by the formula  $2\text{PbCO}_3, \text{Pb}(\text{OH})_2$ .

**WHITE LEAGUE, The,** in American history, a popular name for a semi-military organization, gathered to repress the negroes of the State of Louisiana, who, it was asserted, were meditating insurrection. The organization had its inception in New Orleans in 1874 and on the refusal of the city authorities to allow the landing of a cargo of firearms, which the league had imported from New York, a riot ensued which resulted in more than 100 deaths. The league afterward became a powerful factor in Louisiana politics.

**WHITE METAL,** a term used for an alloy of lead, antimony and tin used for bearings in machinery. Also applied to many other alloys that have a white color.

**WHITE MONKS.** See *Bernardines* under **ORDERS, RELIGIOUS.**

**WHITE MOUNTAINS,** a group of peaks and hills, or a range of monuments, principally in New Hampshire, in the northern part; but which extend into Maine on the east and on the west are connected with the Green Mountains in Vermont. They belong to the Appalachian system. Mount Katahdin, in Maine, is the highest elevation on the eastern rim, and in New Hampshire there are about 20 peaks, with deep narrow valleys and long lines of rounded foot-hills. The peaks are in two groups; the eastern or White Mountain group proper and the Franconia group, separated by a tableland varying from 10 to 20 miles in width. The principal summits of the eastern group are, beginning at the Notch and passing around to Gorham, Mounts Webster, Clinton, Pleasant, Franklin, Monroe, Washington, Clay, Jefferson, Adams and Madison. Of these Mount Washington is the highest and is indeed the highest mountain summit in New England, being

6,293 feet above the level of the sea. The principal peaks of the Franconia group are Pleasant, Lafayette, Liberty, Cherry and Moosehillcock. Near the southern border of the plateau are Whiteface, Chocorua, Red Hill and Ossipee, and in the southeast, Kearsarge. North of the plateau and near the upper waters of the Connecticut, are several elevations, among which are the twin mountains known as Stratford peaks. The plateau is deeply furrowed by several streams. The geological formation of the White Mountains is almost entirely of ancient metamorphic rocks. In many of the peaks the upper portion is composed of huge masses of naked granite or gneiss, and the debris which in the course of ages has clothed the lower portion with a coarse gravelly soil, possesses only enough of the constituents of vegetable life to support those trees and shrubs which will grow in the hardest and poorest soil. Land slides, the result of dislodgment of bowlders and loosely adherent soil after heavy rains, are not infrequent. One of these occurred in the notch of the White Mountain group in August 1826 and destroyed a whole family named Willey. The most noteworthy of many waterfalls among the mountains are the Artist's Fall in North Conway; the Silver Cascade, a beautiful thread of water descending from far up the side of Mount Webster; Ripley's Falls, on a tributary of the Saco, below the Willey house, the lower one, Sylvan Glade cataract, falling at an angle of 45 degrees, 156 feet, in a stream from 50 to 75 feet in width; the falls of the Ammonoosuc, which in a course of 30 miles descends over 5,000 feet; the Berlin Falls on the Androscoggin, descending over 200 feet in the course of a mile, and the Crystal Cascade and Glen Ellis Fall, near the Glen house, on a tributary of the Androscoggin. Of the "notches," or passages (not rent through the solid granite of the mountains by some violent convulsion of nature as has often been supposed, but carved by the slow action of rivers), there are five, the White Mountain Notch, two miles in length and at its narrowest point only 22 feet wide, through which the Saco River passes; the Franconia Notch, which permits the passage of the Pemigewasset; the Pinkham Notch, through which a branch of the Saco and one of the Androscoggin find their way, and the Grafton and Dixville notches, through which flow the Androscoggin and one of its tributaries. The first two of these are those best known. "The Flume" at Franconia Notch is the most noted of those narrow waterways excavated through the rock, though there are others hardly inferior to it in attractiveness. Among the other objects of interest in the Franconia group is the "Old Man of the Mountain," a well-defined profile of the human face formed by three projecting rocks. (See **FRANCONIA**). At the base of the mountain lies a beautiful lakelet one-fourth of a mile long and one-eighth wide, called "Profile Lake," or the "Old Man's Wash-bowl." Five miles south of the notch is the "Basin," a circular bowl-like cavity 45 feet in diameter and 28 in depth, produced by the whirling of large stones in a natural hollow in the rock by the current. It is filled with clear sparkling water, which flows down the mountains in a succession of beautifully clear

s. The "Pool," in the same vicinity, is all well in the solid rock 60 feet in diameter and 190 feet deep, of which 40 feet is water. The White Mountains were first visited by a white man, Darby Field, of Pascataquac, in 1671, when with two Indians he ascended the mountains. Later in the same year General Washington and his companions explored the mountains and discovered the sources of the Saco, Connecticut, Androscoggin and Kennebec rivers. The White Mountains are a famous summer resort. Several railroads enter the mountains, and the seasons special trains carry passengers direct from many of the large cities.

**WHITE OAK SWAMP, Battle of.** See **WHITE PLAINS, BATTLE OF.**

**WHITE PLAINS, N. Y.,** village, county seat of Westchester County, on the Harlem Division of the New York Central and Hudson River Railroad, about 20 miles from the center of New York City. It has several factories and has grown rapidly as a residential suburb. It has a high school, opened in 1886, graded elementary public and parish schools, Saint John's Academy for Boys, Good Samaritan Training School, several private schools and a public library. Bloomingdale Asylum for the insane occupies a prominent position overlooking the village, nearby are several beautiful parks, connected with the water supply of New York City. Several golf clubs maintain courses and grounds, as does also the Westchester Golf Association. It has been an incorporated town since 1886, and owns and operates the water works. The government is vested in a town and board of trustees. Pop. 19,287. The White Plains and vicinity were the scene of many battles and skirmishes during the Revolutionary War. Fortifications on their ruins were seen on all sides. On 21 October Washington established his headquarters at White Plains. On the evening of 27 October Haslett with 1,600 American troops had taken possession of Chatterton Hill, a commanding eminence on the west side of the Bronx, and on the morning of the 28th, re-enforced by a small tactical force under McDougall and two companies of cannon under command of Alexander Hamilton, he fortified his position as well as he could allow. On the morning of that day Howe advanced with his forces in two columns (numbering about 13,000 men) upon the American army posted along the Bronx. Perceiving the importance of the position on Chatterton Hill and regarding it as the only assailant point of the American army, Leslie was sent with a strong detachment to cross the river and attack it in front, while Rall with a regiment was ordered to cross the river at a quarter of a mile below and attack the American in flank. The hill was carried with difficulty, the Americans retreating in order and without being pursued. The American troops rested that night on Chatterton Hill. The next day, 29 October, a skirmish took place between the two armies; but Howe, perceiving the Americans still too strongly posted to be attacked with safety, waited for reinforcements. These arrived on the evening of the 30th, but a storm coming on, the Americans took advantage of it and withdrew to the still

stronger position of Newcastle, two miles above, which they had previously fortified. Afraid to attack them in this position, Howe fell back to the junction of the Harlem and Hudson rivers and encamped on Fordham Heights, and Washington withdrew his army leisurely into New Jersey and made his headquarters at Hackensack. The loss of the Americans in the battle of White Plains and the skirmish of the succeeding days were nearly 300 in killed, wounded and prisoners, and that of the British about the same.

**WHITE RIVER,** in Arkansas, has its rise in the Ozark Mountains, in the northwestern part of the State, flows northeast into Missouri, forming a large curve and entering Arkansas again in Marion County, then flows southeast to the Mississippi River. It enters the Mississippi through several channels, some of which pass through the mouth-channels of the Arkansas River. Except in the highlands of the Ozark Mountains, the greater part of the course of the river is through marshy forest land. It is navigable to Batesville, about 300 miles. The total length is about 500 miles.

**WHITE RIVER,** in Indiana, the chief branch of the Wabash in the State, is formed by the confluence, in Pike County, of the East and West Fork, which have their rise near the eastern boundary of the State. From the junction of the two forks to the mouth of the White, where it enters the Wabash, is 50 miles; the total length from the source of the West Fork is 350 miles. The river is navigable to Martinsville on the West Fork and to Rockford on the East Fork.

**WHITE RIVER,** in South Dakota, the chief river of the southwestern portion of the State, rising in Dawes County, northwestern Nebraska, and flowing northeast into South Dakota, through Shannon and Washington counties, thence easterly to the Missouri River, which it joins a little south of Oacoma. The territory drained is locally known as the "Bad Lands," length about 425 miles.

**WHITE RIVER JUNCTION, Vt.,** village in Windsor County, on the Connecticut River at the mouth of the White River and on the Central Vermont, the Boston and Maine and the Woodstock railroads, about 65 miles south by east of Montpelier and 14 miles east by north of Woodstock. It is a commercial centre for a large agricultural region in both Vermont and New Hampshire. The national bank has a capital of \$100,000 and deposits amounting to over \$1,275,000; the savings bank has deposits amounting to \$481,150. White River Junction is in the town of Hartford and the government census does not give the population of the village separate. Pop. 4,179.

**WHITE SAGE.** See **EUROTTA; GOOSEFOOT.**

**WHITE SANDS.** A remarkable accumulation of granular gypsum in the Tularosa Desert in west-central part of Otero County, N. Mex. It consists mostly of dunes five to 50 feet high of dazzling whiteness and covers an area of about 270 square miles and its amount is at least 2,000,000,000 tons. Most of the material is nearly pure gypsum containing about 95 per cent of that mineral. To the north it grades into quartz sand. Attempts have been

made to utilize the deposit for manufacture of plaster of paris but local demand for this product is small and cost of long distance shipment is too great. The gypsum was carried into the basin in solution from the adjoining mountains and after crystallizing by evaporation of the water has been blown by the wind into dunes. Some of it is brought to the surface by ground water.

**WHITE SEA**, northern Russia, a large gulf opening into the government of Archangel, between the Kola Peninsula on the west and the Kanin Peninsula on the east. Near its mouth, and on the eastern side, is a branch called the Gulf of Mezen, which receives the waters of the river Mezen, and the inner part of the sea sends off three large arms, namely, the Gulf of Kandalak, penetrating northwest into Lapland, the Gulf of Onega, receiving the river Onega and the Gulf of Archangel, into which flows the Northern Dvina. Of the islands in the sea, Solovetskii is the largest. The White Sea is comparatively shallow, and is frozen over from October to May. Archangel, at the mouth of the Northern Dvina, is the leading port of northern Russia, and other ports on the shores of the sea are Onega and Kem. Canals connect the White Sea basin with basins of the Caspian, Baltic and Black Sea.

**WHITE SULPHUR SPRINGS**, Mont., city, county-seat of Meagher County, about 65 miles east by south of Helena. It is reached by stage from the Northern Pacific Railroad, a distance of about 40 miles. It is the commercial centre of a large agricultural, stock-raising and mining region and is noted for its thermal springs. The national bank has a capital of \$100,000. Pop. 417, which includes only those within the limits and not the number who transact business in the city.

**WHITE SULPHUR SPRINGS**, W. Va., a district in Greenbrier County, on the Chesapeake and Ohio Railroad, about 230 miles west by north of Richmond and 90 miles west of Staunton. The locality has long been noted for its medicinal springs. The temperature of the water is 62° F. It is a famous health-resort. Pop. 338.

**WHITE-SWELLING**, any severe disease of the joints resulting from chronic inflammation in the bones, cartilages or membranes. The knee, ankle, wrist and elbow are the joints most subject to this form of disease. It is distinguished from simple inflammation of the synovial membrane (synovitis) by the fact that the synovial membrane passes into pulpy degeneration. Amputation is frequently necessary. The disease may be local or constitutional in origin, being in the latter case due to rheumatism, gout, syphilis, pyæmia, etc.

**WHITE WHALE**. See **WHALE**.

**WHITEAVES**, Joseph Frederick, Canadian paleontologist: b. Oxford, England, 26 Dec. 1835; d. 8 Aug. 1909. He studied at the University of Oxford in 1858-61 and made investigations of the land- and fresh-water mollusca and fossils of the oolitic rocks in the vicinity of Oxford, adding considerably to the information possessed. He removed to Canada in 1861, was engaged in geological investigations in Montreal and Quebec in 1861-62, and

in 1863-75 he was curator of the museum and secretary of the Natural History Society of Montreal. He made a special study of the land- and fresh-water mollusca of Lower Canada in 1867-73. He was appointed to the Canada Geological Survey in 1875, became its paleontologist in 1876, and in 1877 was appointed zoologist and assistant director. He was one of the original Fellows of the Royal Society of Canada and contributed to the society's *Transactions* as well as to the *Canadian Naturalist* and similar periodicals.

**WHITEBAIT**, a small fish, called by Valenciennes *Rogenia alba*, and for which he constituted the genus *Rogenia* as a distinct genus of the Herring family (*Clupeidae*), but which is now regarded by naturalists as merely the fry of the herring or of similar fish. The whitebait-fishery is actively prosecuted on several parts of the British Coast, particularly in the estuary of the Thames, where the whitebait is very abundant in spring and summer, beginning to appear in the end of March or early in April. Adult whitebait are caught on the coast of Kent and Essex during winter, and in that condition are about six inches in length. Whitebait is found also in the Forth. It is much in request as a delicacy for the table. At the time when ordinarily captured, whitebait are only from one and one-half to four inches in length. They are caught by means of bag nets sunk four or five feet below the surface of the water. For several months they continue to ascend the river in shoals with the flood-tide and descend with the ebb-tide, not being able to live in fresh water. They are fried with flour or crumbs; they are often laid on a napkin and sprinkled with fine flour and a little salt, rolled about till well covered with flour and then thrown into a pot of boiling lard, where they remain till they are of a pale-straw color. The whitebait has the body more compressed than the mature herring; belly serrated; lower jaw longer than the upper; scales very soft, small and thin, and very easily rubbed off; color silvery white, greenish on the back. The food of the whitebait seems to consist of minute crustaceans. It is probable that under the name whitebait the fry of all the British *Clupeidae* — the pilchard, the sprat and the shad — are indiscriminately taken and used like the fry of the herring.

**WHITECHAPEL**, London, England, a parish and parliamentary district, east of the nucleate city of London, one of the poorest portions of the metropolis, and formerly notorious for its criminal population. From 1888 to 1891 it was the scene of the atrocities of the mysterious Jack the Ripper. Within its boundaries are the Tower of London and London Hospital, and it is intersected by Whitechapel Road. The name is derived from a former medieval chapel, whence all distances east of London were calculated. The pop. is about 100,000.

**WHITEFIELD**, Whit'feld, George, English evangelist, founder of the Calvinist Methodists: b. Gloucester, 16 Dec. 1714; d. Newburyport, Mass., 30 Sept. 1770. He was sent to the grammar school of Saint Mary de Crypt at Gloucester, and at 18 entered as servitor at Pembroke College, Oxford, where he became acquainted with the Wesleys, and

the small society which procured them ne of Methodists. Hearing of his de tendencies, Dr. Benson, bishop of ter, made him an offer of ordination at ch he accepted, and he was ordained a in 1736. Such was his powerful and preaching, that, after his first sermon .ester, a complaint was made to the that he had driven several people mad; ch the prelate observed that he hoped lness would not be forgotten before the unday. He for some time supplied a at Dummer, in Hampshire, but the next sent him by the Wesleys of their s in Georgia excited in him a desire to in their labors, and he arrived at ah in May 1737. Observing the deplor- nt of education in the colony, he pro- an orphan-house for which he ded- to raise contributions in Eng- here he arrived in the beginning of Although discountenanced by many of gy, Bishop Benson did not scruple to on him priest's orders; and on going to the churches in which he preached capable of holding the crowds assembled. n adopted the practice of preaching in en air, which he first carried out at ood, near Bristol, among the colliers, on his discourses produced a surprising and whose vicious manners and habits bly improved. He afterward preached open air in Bristol, and in Moorfields, gton, and other places in the neighbor- f London, to vast assemblages of peo- 1 August 1739, he again embarked for a, and made a tour through several provinces, where he preached to im- audiences, with an effect vividly por- in the autobiography of Benjamin n. His preach- with great opposition in New England time and Harvard College put forth a ny" against him. Returning to England 1748 he was soon after introduced to ntess of Huntington, who made him her chaplains. A visit to Ireland and ore voyages to America followed, and eral years his labors were unremitting. ached at Exeter, N. H., the day before th, and also at Newburyport. He is beneath the pulpit of the Federal Street at Newburyport. His works were pub- n 1771-72. Consult Gillies, 'Memoirs' 7). Tyerman, L., 'Life of Whitefield'

**ITEFISHES**, a name given in the States to various species of salmonoid f the genus *Coregonus* and sometimes e of *Argyrosomus*, more properly desig- iscoes. *Coregonus* has a comparatively and nearly toothless mouth, the pre-

maxillary bones broad and with the edge nearly vertical, and the lower jaw short. The thin cycloid scales are much larger than in the salmon and trouts, and the caudal fin is deeply forked. Internally, the stomach is horse-shoe shaped and provided with very numerous pyloric caeca, and the swim-bladder is very large. The species, about 15 in number, though some ichthyologists recognize many more, are confined to the clear lakes of the northern portions of the northern hemisphere often extending into the Arctic regions and sometimes there becoming anadromous. Wherever found they are highly valued for food. North America has about eight species. The common whitefish (*C. clupeiiformis*) has its centre of distribution in the Great Lakes, but extends into the various lake systems of New York and southern Canada. It reaches a length of two feet and may be distinguished from the related species by its numerous and long gill-rakers, the toothless mouth and the elevated but not compressed back. As generally in the whitefishes, the color is olivaceous above and white below. It receives various local names from the fishermen, such as buffalo-back; and the variety landlocked in Otsego Lake at the head of the Susquehanna River is known as the Otsego bass. During the greater part of the year the whitefish remains in the deeper waters of the lakes, moving about in schools which change their feeding grounds with considerable regularity. Being toothless they feed only upon small animals, such as crustaceans, snails and insect larvæ, the first being by far the most important part of their diet. During the late fall and early winter the schools congregate on the shallows to spawn; in the act of spawning the female rises to the surface and is immediately followed by a male which mingles the sperm with the stream of eggs issuing from her vent. The eggs are about one-eighth of an inch in diameter and sink to the bottom, where most of them are eaten by the small fishes and mud-puppies which swarm on the spawning grounds. They develop slowly and require several weeks to hatch, the exact time depending upon the temperature of the water. Each female produces from 10,000 to 75,000 eggs, depending upon her size.

Besides the enemies affecting the eggs and young the adult whitefish are preyed upon by the large pike and lake-trout which follow the schools, and to a less extent by smaller predaceous fishes. The extensive development of the fisheries, which are prosecuted most vigorously at the very season when the spawning fish are most accessible on the shallows, has so depleted the numbers of the whitefish that the fisheries are now dependent upon artificial propagation for their maintenance. The methods are essentially the same as those employed in the artificial propagation of the shad, though many modifications in detail have been found necessary. Hundreds of millions of eggs are now annually taken and hatched under the auspices of the United States and State commissions of fisheries. Such extensive and even greater operations are required to sustain these fisheries at a point of production equal to satisfying the demand of the market. These figures represent the American catch alone and during the same year the Canadian fisheries prob-

ably yielded about 40,000,000 pounds more. Whitefish are sold fresh or are frozen immediately after capture and placed in cold storage at a temperature several degrees below freezing and in this condition shipped, especially during the winter, to all parts of the country. Relatively small quantities are also pickled or smoked.

Other species of *Coregonus* are found in the Great Lakes as well as in other lakes particularly northward and westward, but at the present time none are so highly valued as the common whitefish. An important one is the shad-waiter or round whitefish (*G. quadrilateralis*). The genus *Argyrosomus*, however, includes two species of great and increasing importance, though inferior in quality to the common whitefish. The genus differs from *Coregonus* chiefly in the projecting lower jaw, larger mouth and horizontal premaxillary bones. The numerous species are similarly distributed in North America, which has eight, Europe and Asia, and except for their great activity and predatory mode of life their habits in general resemble those of the true whitefishes. The cisco whiting or lake herring (*A. arctedi*) is about a foot long, bluish or greenish above, with dark, speckled silvery sides. It abounds in shallow waters of the Great Lakes and, as indicated above, is of great commercial value. The moon-eye cisco (*A. hoyi*) has a very large eye and the sides are brilliantly silvery. It is about a foot long and is the object of a considerable fishery in the western part of Lake Michigan. It spawns in November in relatively deep water. A third important species of this genus is the blue-fin whitefish (*A. nigripennis*), distinguished from all of the preceding which have pale fins by the blue-black color of its pectorals, anals and ventral. It attains a length of 18 inches and is plentiful in the deep waters of Lake Michigan and the small lakes of Minnesota and Wisconsin and thence northwestward to Athabasca.

Whitefishes seldom take the hook, but are captured by means of pound, trap and gill nets and to a smaller extent with seines. The pound and trap nets are arranged in lines which sometimes reach to a distance of 10 or 12 miles from shore, while the gill nets are set much farther out in deep water and are weighted to the bottom.

Consult Brown Goode, 'Natural History of Aquatic Animals' (Washington 1884), and 'American Game and Food Fishes' (New York 1902); Townsend, 'Statistics of the Fisheries of the Great Lakes,' Report United States Fish Commission for 1901; and special papers of the United States Bureau of Fishes, and of the Canadian Fisheries Department.

**WHITEHALL**, London, England, a street leading from Parliament Square to Trafalgar Square, containing several public offices, and named after a palace that once stood there. The building known as the Horse Guards, the office of the commander-in-chief of the army, is so called in consequence of being the station where that part of the troops usually do duty. The treasury, near the Horse Guards, is built on the site of part of the old palace; the First Lord of the Treasury, however, has his official residence in Downing Street, where also the Cabinet meets. The Admiralty Office contains

the offices connected with the administration of the naval affairs of the country. The original Whitehall succeeded a palace built by Hubert de Burgh before the middle of the 13th century. It afterward came into the possession of the archbishops of York, was inhabited by Wolsey (under the name of York Place), then passed to Henry VIII and was called Whitehall. Charles I was executed in front of Whitehall and he was led to the scaffold out of one of the windows. Oliver Cromwell died in Whitehall. In 1697 the building was destroyed by fire, except the banqueting hall, which had been added by James I, according to a design of Inigo Jones, in 1619. This portion still remains and chiefly consists of one room, of an oblong form and 40 feet high. The ceiling, representing the apotheosis of James I, was painted by Rubens and was retouched by Cipriani. This building was long a royal chapel, but it now contains the museum of the Royal United Service Institution.

**WHITEHALL**, Ill., city in Greene County, on the Chicago and Alton and the Chicago, Burlington and Quincy railroads, about 25 miles southwest of Jacksonville and 63 miles north of Saint Louis. It is in an agricultural and stock-raising region and in the vicinity are deposits of fire clay. The chief manufactures are flour, sewer-pipe, tiles, stoneware and machinery. Its shipping trade is chiefly in farm and dairy products, livestock and clay products. There are six churches, a high school and library. The two banks have a combined capital of \$100,000. Pop. 2,854.

**WHITEHALL**, N. Y., village in Washington County, on Lake Champlain, Poultry River, the Champlain Canal and the Delaware and Hudson Railroad, about 75 miles north by east of Albany. It is at the foot of Skene's Mountain, in a narrow valley. It has railroad shops, silk and knitting mills, grist mills, lumber mills and machine shops. It has a high school and a library. The bank has a capital of \$50,000 and deposits (1903) of nearly \$700,000. The village owns and operates the waterworks. The government is vested in a board of trustees and a president chosen annually by popular vote. In 1761 Whitehall was settled by Major Philip Skene and a colony of about 30 families; in November 1763 it was incorporated. When differences arose between America and England, which culminated in the Revolution, Skene joined the British and the Americans took possession of his property. An American garrison was stationed at Whitehall in 1776; but fearing capture by Burgoyne, they destroyed the fort, and the houses, and abandoned the place. At the close of the war nearly all the people returned and claimed their former holdings. The whole of the Skene property was sold at auction, and the highest bidder gave £11 10s. In 1806 it was incorporated as a village. In 1812 when the Lake Champlain towns and villages were again near the centre of danger, a fort and block house was built. In 1819 the Champlain Canal was built from Whitehall to Fort Edward, and five years later it was extended to Troy. Pop. 4,666.

**WHITEHAVEN**, England, a seaport and important coal-mining centre in Cumberland, situated on a bay of the Irish Sea, 40 miles

est of Carlisle. It is well built, and has a custom-house, market-house, public baths, with swimming-pond; a good harbor and a deepwater dock. There is a considerable shipping coals, iron-ore, pig-iron, steel rails, etc., exported and American and other produce. The manufactures comprise sail-cordage, anchors, nails, cement, alabaster, ware, candles and soap. Iron shipping also is carried on, and there are blast-furnaces, iron- and brass-foundries, engineering flour- and saw-mills, breweries, a tannery, etc. There are here extensive coal mines, in which a large number of the natives are employed. The coal-mines, which have been worked since the 17th century, extend several miles under the sea, and coal is mined in the town. Pop. 20,000.

**WHITEHEAD, Charles**, English poet: b. London, 1804; d. Melbourne, Australia, 5 July 1872. He was engaged in a London mercantile business until 1857 when he went to Australia and engaged in journalism. He was the author of numerous poems, plays and sketches, among which are 'The Solitary' (1831); 'The Autobiography of Jack Ketch' (1834); 'The Cavalcade' (1836); 'Richard Savage' (1842), recently dramatized; 'Smiles and Tears, or Romance of Life' (3 vols. 1847); 'Life and Letters of Sir Walter Raleigh' (1854), etc. He was the friend of T. B. Bell, Mackenzie, 'Charles Whitehead, a Titan Genius' (1884).

**WHITEHEAD, Cortlandt**, American Episcopalian bishop: b. New York, 30 Aug. 1802. He was graduated from Yale in 1823 and from the Philadelphia Divinity School in 1825. Ordained to the priesthood in 1826 he engaged in pastoral work in Colorado for several years and was rector of the Church of the Holy Trinity, South Bethlehem, Pa., 1870-82. In July 1882 he was consecrated bishop of Virginia.

**WHITEHEAD, William**, English poet: b. London, 1715; d. London, 14 April 1785. He was educated at Winchester and Clare Hall, Cambridge, was appointed secretary and registrar of the order of the Bath in 1755, and in 1756 was appointed poet-laureate, in succession to John Dryden (q.v.). His identity is frequently confused with that of the satirist Paul Whitehead. He was the author of the tragedy 'The Roman Father' (1750); and 'Creusa, or Athens' (1754); the comedy, 'The Rivals' (1762); a farce, 'The Trip to Italy' (1770); and numerous minor works.

His collected works were edited and published with a memoir by William Mason in 1785. Consult Thompson, E., 'Poems and Miscellaneous Compositions of P. Whitehead' (1777).

**WHITEHILL, Clarence Eugene**, American singer: b. Marengo, Iowa, 5 Nov. 1872. He studied under L. A. Phelps in Chicago and was engaged as a church singer until, following the advice of Madame Melba, he went to Europe to study for the operatic stage. He studied under Giraudet and Sbriglia in Paris. In 1900 made his debut successfully at the Grand Opéra Comique in Paris. He studied the Wagnerian rôles with Cosima Wagner and

was highly successful in them. He appeared at Baireuth, and at Covent Garden, London; and after 1909 at the Metropolitan Opera Company, New York, and with the Chicago Opera Company.

**WHITEING, Richard**, English journalist and novelist: b. London, 27 July 1840. He was educated privately and began his career in journalism in 1866 with a series of satirical sketches on social and political topics afterward republished as 'Mr. Sprouts—his Opinions' (1867). He was subsequently engaged on the *Morning Star* as leader-writer, and was afterward Paris correspondent for various New York, London and Manchester papers, but returned to London to join the editorial staff of the London *Daily News*, a position he resigned in 1899. He has written 'The Democracy' (1876); 'The Island' (1888); 'No. 5 John Street' (1899); 'The Life of Paris' (1900); 'The Yellow Van' (1903); 'All Moonshine' (1907); 'My Harvest' (1915), etc.

**WHITELOCKE, hwit'lök, Bulstrode**, English statesman: b. London, 2 Aug. 1605; d. Chilton Park, Wiltshire, 28 July 1675. Educated at Oxford he studied law at the Middle Temple, was called to the bar in 1626, and entered Parliament as member for Stafford. He was elected to the Long Parliament of 1640 from Great Marlow, was chairman of the committee for drawing up Stafford's charges of impeachment, and one of the commissioners appointed to treat with the king at Oxford. As a member of the Westminster Assembly (1643) he opposed the adoption of Presbyterianism, and as a commissioner of the Great Seal (1649) withheld consent to the king's death. In 1623 he was Ambassador to Sweden, where he concluded a treaty with Queen Christina, and on his return was speaker of the House of Commons (1656), and one of Cromwell's lords (1657). From his manuscripts have been published 'Memorials of English Affairs from the Beginning of the Reign of Charles I to the Restoration' (1682; new ed. 1852); 'Memorials of English Affairs from Bruce to the End of the Reign of James I' (1709); 'Journal of the Swedish Embassy' (1722; new ed., 1845), and other works.

**WHITESTONE, N. Y.**, in New York City, borough of Queens. The village was a place of importance, on account of its good harbor, and its position near the eastern entrance to New York Harbor. It is near the United States military post at Willett's Point and Fort Schuyler, on Throgg's Neck. Pop. 3,000.

**WHITETHROAT**, a bird, either of two species of Old World warblers—*Curruca cinerea*, the greater, and *C. sylvicola*, the lesser whitethroat; or a hummingbird (*Leucochloris albicollis*) of Brazil; or a whitethroated sparrow (*Zonotrichia albicollis*), commonly known in the eastern United States, where it is a migrant, as Peabody-bird.

**WHITEWASH**, a milky fluid produced by mixing good slaked lime with water: used as a cheap coating for walls, fences, etc. When mixed with a little size and sometimes colored it is used on interior walls under the name of calcimine.

**WHITEWATER, Wis.**, city in Walworth County, on the Whitewater River, and on the

Chicago, Milwaukee and Saint Paul Railroad, about 46 miles southeast of Madison and 50 miles southwest of Milwaukee. It is in an agricultural and stock-raising region and has creameries, paper mill, wagon works, sash and door factories, flour mill, machine shops and furniture factory. It has a State normal school, a high school, opened in 1886, public and parish schools and a public library. There are two banks and a newspaper. Pop. 4,000.

**WHITEWOOD.** See LINDEN.

**WHITFIELD, hwi't'feld, or WHITFELD, Henry,** English clergyman: d. Winchester, England, about 1658. Of the date of his birth and his early life nothing is definitely known. He appears to have been appointed to the living of Ockley, Surrey, in 1616, but having protected several Puritan clergymen during the Laudian persecution incurred the displeasure of Laud, which was further increased by his refusal to read to his parishioners from the 'Book of Sports.' He, therefore, emigrated to New England in 1637 with many followers and was one of the founders of Guilford, Conn. In 1650 he returned to England and was minister at Winchester. His writings include 'Some Helpe to Stirre up to Christian Duties' (3d ed., 1636); 'The Light Appearing more and more toward the Perfect Day' (1641); and 'Strength out of Weakness' (1652).

**WHITFIELD, Robert Parr,** American geologist: b. New Hartford, N. Y., 27 May 1828; d. 1910. He studied natural history and geology almost unaided, was assistant on the New York State geological survey in 1856-76, and in 1872 was attached to the United States Geological Survey. He was instructor in geology at the Rensselaer Polytechnic Institute in 1872-75, professor in 1875-78 and for many years after 1887 was curator of the American Museum of Natural History in New York.

**WHITGIFT, John,** English prelate: b. Great Grimsby, Lincolnshire, about 1530; d. Lambeth, 29 Feb. 1604. He was educated at Pembroke Hall, Cambridge, and after the accession of Elizabeth took holy orders (1560) and was made chaplain to Cox, bishop of Ely. In 1563 he was appointed Lady Margaret professor of divinity at Cambridge, in which office he gained a high reputation by his lectures on the book of Revelations and the Epistle to the Hebrews, and in 1567 was elected master of Pembroke Hall. Soon after the queen made him her chaplain and master of Trinity College, Cambridge, and the same year he also became regius professor of divinity. He was made dean of Lincoln in 1571, and in 1576 bishop of Worcester, and, being also vice-president of the marches of Wales, made constant use of both the temporal and spiritual powers to put down Roman Catholicism and Puritanism within the limits of his jurisdiction. In 1583 he became archbishop of Canterbury, and soon exacted from every clergyman in the church a subscription to the three points of the queen's supremacy, the lawfulness of the common prayer and ordination service, and the truth of the whole 39 articles. Making use of the court of high commission he removed from positions in the church all non-conformists. In 1585 the star chamber, at his instigation, passed ordinances for the regulation of the press, by which

no one was allowed to print except in Oxford and Cambridge; the number of copies was to be determined by the ecclesiastical commissioners; and none but a few specified persons were to be suffered to print any book or thing whatsoever until it should be examined and allowed by the archbishop of Canterbury and the bishop of London; and every printer who printed any book contrary to the intent of the statute was to be imprisoned for three months. In 1586 he was sworn of the Privy Council and framed the statutes of cathedral church hospitals and grammar school at Croy founded by Whitgift. Consult 'Life of Strype' (1718) and by Sir George Peck and Frere, W. H., 'The English Church, 1558-1625' (London 1904).

**WHITING, hwi't'ing, Arthur,** musician: b. Cambridge, Mass., 20 July 1857. He studied music in Munich at the Royal School with Rheinberger. He is a pianist and has composed orchestral and chamber music, as well as numerous songs, pianoforte concertos and sacred music. His series of "University Concerts" have been well received at Harvard, Yale and Princeton and other colleges.

**WHITING, George Elbridge,** musician and composer: b. Holliston, Sept. 1842. He early displayed musical talent and was engaged as an organist successively at Hartford, Conn., Boston and at Altamont, N. Y. He studied in Europe in 1863 and in 1864 was organist at the church of the Immaculate Conception, Boston, in 1876-78 and has since that position since 1883. In 1878-80 he was organist at the Cincinnati Music Hall and professor of organ and composition at the Cincinnati College of Music. He was a successful teacher in the New England Conservatory of Music for several years but resigned in 1893. His compositions include 'Grand March' (1876); 'Tale of the Viking'; 'Dream Picture' (1877); 'Midnight, Cantata'; a one-act Italian, 'Lenora' (1893); and numerous lullabies, symphonies, etc.

**WHITING, Lilian, American,** b. Niagara Falls, N. Y., 3 Oct. 1857. She was prominent in journalism in Saint Louis, Mo., in 1880-90 was literary editor of the 'Traveler' and was editor of the 'Boston Herald' in 1890-93. Her published books are characterized by familiarity with occult subjects and a disposition to lead her readers unconsciously to recognize the genuineness of mystical and spiritualistic teaching. They include 'Dreamland Sent.' verse; 'The Wonderful' (3 vols., 1894-96-98); 'Kate Field's Story' (1899); 'The World Beautiful' (1901); 'Boston Days' (1902); 'The World Beautiful' (1905); 'Life Transfigured' (1906); 'The Brownings — Their Life and Art' (1907); 'Athens the Violet Crowned' (1911); 'Lure of London' (1914); 'Women Venerated' (1915); 'Canada's Story' (1917); 'The Adventure' (1917).

**WHITING, William Henry C.** Confederate soldier: b. Miss., 1825; d. Governor's Island, New York, 10 March 1865. He was graduated from the United States Military Academy at West Point, N. Y., in 1845.

in 1845. He entered the engineering corps and was engaged in military construction work, reaching the rank of captain in 1858. He resigned from the army 20 Feb. 1861 and entered the service of the Southern Confederacy. He was chief engineer of the Army of the Shenandoah under Gen. J. E. Johnston in June and July 1862, holding the rank of major; and was promoted brigadier-general 27 Aug. 1861. He saw service at the first battle of Bull Run and at the battle of West Point, Va. He was promoted major-general in 1863, built Fort Fisher, N. C., and in 1864 was placed in command there. He was wounded and taken prisoner when Fort Fisher fell, 15 Jan. 1865, later dying from his wounds.

**WHITING**, Ind., town in Lake County, on Lake Michigan, and on the Pennsylvania Railroad, about 16 miles southeast of Chicago. It has a good harbor and steamer connections with the Lake Michigan ports. It has a large oil refinery, machine shops and several industrial establishments connected with refining and shipping petroleum and with shipping farm products. The manufacturing establishments, though small in number, are capitalized for over \$15,000,000, and the value of the annual products is about \$20,000,000. Pop. 6,587.

**WHITING**, a name applied to several quite unrelated fishes probably in allusion to the noteworthy whiteness of their flesh, or, in some cases, of the skin of the lower parts. In the United States, and more especially in the South, several species of *Menticirrhus*, a genus of *Scianida*, are known as whiting, but more widely as kingfishes (q.v.). The common whiting (*M. americanus*) reaches a length of about a foot; the body is elongated and slender with a high spinous dorsal and a long low soft dorsal fin, an undulate caudal fin, and is completely covered with ctenoid scales; the outer row of teeth of the upper jaw are enlarged and strong and the color silvery gray with faint oblique dusky bars. It is very common along sandy shores of the entire Gulf Coast and on the Atlantic Coast northward to about the mouth of Chesapeake Bay and southward to Brazil. Though remaining on these coasts throughout the year they are most plentiful in summer when they frequent the bays and estuaries, but prefer strong currents and the deeper waters. They feed upon crabs, shrimps and other crustaceans, and being vigorous biters and gamy fighters afford splendid angling. Great numbers are caught on lines for the market and the flesh is unusually firm, delicate and well-flavored. Spawning is said to occur in May. The surf whiting (*M. littoralis*) is so called because, unlike the last, it frequents shallow waters along sandy shores and is captured in large quantities by means of seines. The outer teeth of the upper jaw are not enlarged; the gill-rakers are better developed than in the common whiting; and the black tip of the caudal fin is another mark of distinction. The common northern kingfish (*M. saxatilis*) also extends into southern waters and is there confused with the above species under the name of whiting. It may be recognized by its dusky color and the distinct, dark bands which cross the sides obliquely. Other species occur on the Pacific Coast. By the New England fisherman the name of whiting or silver hake is given to a

common species of the cod family (*Gadida*), the *Merluccius bilinearis* of American ichthyologists, though many European authorities fail to distinguish it from the Old World *M. vulgaris*. From the great majority of the cods the whiting is distinguished by the total absence of a chin-barbel and by the peculiar excavated area of the top of the skull; the second dorsal and the anal fin are long and each divided nearly in two by a deep notch. The body is elongated and covered with small scales; the color grayish silvery white below. This whiting is common in waters of moderate depth along the shores of New England and somewhat northward, and extends southward in deep water to Virginia and even to the Bahamas. Unlike most of the *Gadida*, which are essentially bottom-feeders, it is an active, roving species, which comes to the surface to pursue and feed upon herring and other fishes. Sometimes large schools appear on our coasts and many are captured in purse-seines and pound-nets. Spawning takes place at the bottom on the edge of the continental slope. Owing to its comparatively small size and the softness of its flesh it is one of the least important economically of the family.

The European whiting (*M. vulgaris*) is scarcely distinguishable from the American, but has much smaller scales, fewer spines in the first dorsal fin and larger teeth. It frequents shallower water and is very abundant along the northern coasts of Europe. It makes its appearance in vast shoals, keeping at a short distance from the shore, and is taken by the line in great numbers. It is considered the most delicate and most wholesome of all the species of cod; but it does not attain a large size, usually not exceeding a foot in length and under two pounds in weight. The food of the adults consists chiefly of fishes and of the young of shrimps and other crustaceans. Spawning occurs in, and the young frequent, the shore waters. As long as the young feed chiefly on the bottom they retain a chin-barbel, but as their habits change this degenerates and finally disappears. Other fishes sometimes called whiting are the hog-fish, harvest-fish and a white-fish (q.v.).

**WHITING**, a preparation of white chalk from which the grosser impurities have been removed. It is extensively used in the arts, also for cleaning silver and making putty.

**WHITLEY'S WORKSHOP COMMITTEES, or WHITLEY'S INDUSTRIAL COUNCILS.** See WORKSHOP COMMITTEES.

**WHITLOCK, Brand**, American ambassador and author: b. Urbana, Ohio, 4 March 1869. He was engaged in journalism in Toledo, Ohio, in 1887-90, and was on the staff of the *Chicago Herald* in 1890-93. He was a clerk in the office of the Illinois secretary of state in 1893-97. He had meanwhile studied law and was admitted to the bar of Illinois in 1894 and to that of Ohio in 1897, then establishing himself in law practice at Toledo. He was elected mayor of Toledo in 1905 and served four successive terms, declining a fifth nomination. He succeeded in securing a new city charter providing for the initiative, referendum, recall and direct nominations. He was by this time a well-established magazine writer, producing both verse and prose, the latter dealing in the

main with politics and economics in an uncompromising fashion. He was appointed Minister to Belgium by President Wilson in 1913 and was in office at the outbreak of the European War. He was entrusted with the representation of seven of the warring nations, remaining at his post after the German invasion. His skill in dealing with the difficulties of the situation under the German occupation earned for him a worldwide reputation; and he won scarcely less praise for his handling of the Belgian relief work. The necessity for his leaving invaded Belgium when the United States declared war upon Germany in April 1917 was viewed with deep regret in Belgium. He refused to leave Brussels unless accompanied by the other Americans there, and crossed into Switzerland 4 April 1917. He later visited King Albert of Belgium at the battle front, and after the signing of the armistice in November 1918 he resumed his duties at Brussels. He returned to the United States for a visit in 1919, and while at home the country's representation in Belgium was raised to rank of an embassy, Mr. Whitlock thus becoming Ambassador. He is author of 'The Thirteenth District' (1902); 'Her Infinite Variety' (1904); 'The Turn of the Balance' (1907); 'Abraham Lincoln' (1908); 'The Gold Brick' (1910); 'On the Enforcement of Law in Cities' (1910-13); 'Forty Years of It: An Autobiography' (1914); 'Memories of Belgium Under the German Occupation' (1918); 'Belgium, A Personal Narrative' (1919), etc.

**WHITLOCK, hwit'lök, Elizabeth Kemble**, English actress, fifth child of Roger Kemble (q.v.): b. Warrington, Lancashire, 2 April 1761; d. 27 Feb. 1836. She first appeared at Drury Lane theatre in February 1783, as Portia. In 1785 she was married to Charles Edward Whitlock, a provincial manager and actor, and seven years later accompanied her husband to this country, where they performed for many years in the principal cities. Mrs. Whitlock became the most popular actress of the day in America, and in Philadelphia frequently performed before President Washington and other distinguished persons. She returned to England in 1807 with a competency and thenceforth retired from the stage. In personal appearance and voice she was said to have strongly resembled her sister, Mrs. Siddons.

**WHITMAN, Charles Otis**, American zoologist: b. Woodstock, Me., 14 Dec. 1842; d. 6 Dec. 1910. He was graduated from Bowdoin in 1868, studied at Leipzig, and in 1880-81 was professor of zoology at the Imperial University, Tokio, Japan. He was engaged in further studies at the Naples Zoological Station in 1882, and in 1883-85 was assistant in zoology at Harvard. He was director of the Allis Lake Laboratory, Milwaukee, in 1886-89, and in 1890-92 professor of zoology at Clark University, Worcester, Mass. He became director of the Marine Biological Laboratory at Woods Hole, Mass., upon its foundation in 1888, and from 1892 until his death was at the head of the department of zoology at the University of Chicago. He was elected to the National Academy of Sciences in 1895. He founded the *Journal of Morphology* in 1887, and after 1883 was editor of the microscopical department of

the *American Naturalist*. He has made a specialty of the development of the vertebrates and of the structure and development of worms. His writings include 'Methods of Research in Microscopical Anatomy and Embryology' (1885); 'Biological Lectures' (1890-95); 'The Inadequacy of the Cell Theory of Development' (1893); 'Animal Behavior' (1898), etc.

**WHITMAN, Charles Seymour**, American lawyer: b. Hanover, Conn., 28 Aug. 1868. He studied at Amherst College and then studied law at New York University, and was admitted to the bar in 1894. In 1901 he was appointed assistant corporation counsel of New York City where his effective work won for him the post of city magistrate. In this capacity he founded the Night Court in that city for the immediate trial of all offenders arrested at night. In 1907 Governor Hughes appointed him a judge of the Court of Sessions, and in the following year deputy attorney-general in the investigation of election frauds in the northern part of the State. In 1909 he was elected district-attorney of New York City on a Fusion ticket. In this capacity he secured representation of the district-attorney's staff in the city magistrate's office, and was active in suppressing arson offenders. The noted Becker trial came up during his tenancy of office, and Whitman's mastery of the case was most effective in unearthing and reforming the relations between certain members of the New York City police and professional criminals. The handling of the Schmidt murder case, the prosecution of the poultry trust and of election frauds won for Mr. Whitman the highest commendation. He was renominated in 1913 and elected almost unanimously. In 1914 Whitman was elected to the governorship of New York State. His principal plank was the reformation of the State finances, which he proceeded to institute vigorously by a reorganization of State departments and a thorough investigation of the salaries of Civil Service employees. In 1916 he was elected chairman of the Republican National Convention, where he urged the nomination of Charles E. Hughes for President. In September of the same year he was re-elected to the governorship and established a precedent by sending to every enrolled voter a report of his first term as governor, containing also reports of the heads of other State departments. In connection with the European War, the governor ably supported the Federal administration in war policies and effectively mobilized the State's resources. He also inaugurated a State Constabulary, and a new State Guard to replace the National Guard on service in France. In 1918 he was again nominated for governor on the Republican ticket, but was defeated by Alfred E. Smith, the Democratic candidate.

**WHITMAN, Frank Perkins**, American physicist: b. Troy, N. Y., 29 July 1853. He was graduated at Brown University in 1874 and took his A.M. there in 1877, later studying at Johns Hopkins University. He was professor of physics at Rensselaer Polytechnic Institute, Troy, in 1880-86; and has since occupied that chair at Western Reserve University. He is a contributor to scientific periodicals.

**WHITMAN, Marcus**, American missionary and pioneer. b. Rushville, N. Y., 4 Sept. 1802; d. near Walla Walla, Ore., 29 Nov. 1847. After studying medicine at the Berkshire Medical Institution, Pittsfield, Mass., he practised in Canada for four years. He offered his services as a missionary (1834) to the American Board of Commissioners for Foreign Missions, and in 1835 went with Samuel Parker to explore the region of the Oregon, but did not go beyond Green River. In 1836 having married, with his wife and three fellow missionaries he set out to work among the Indians of the upper Columbia. The party crossed the plains by wagon, being the first persons to reach the Pacific Coast by this route. On 1 May they reached the Columbia River, and located themselves near the site of the present Walla Walla, Wash. They were soon followed by a large number of emigrants, who settled in what was then known as Oregon, and now forms the States of Oregon, Washington and Idaho. At this time the Hudson Bay Company was using every possible means to secure this territory to the English. When this plan became evident to Whitman he decided to take every precaution to forestall it. The Ashburton Treaty was then before Congress, and was expected to settle the Oregon question. In 1842-43 Whitman traveled over 3,000 miles to the East on horseback, enduring all the hardships of a Western winter in the mountains, and according to the statement of H. H. Spalding, one of his missionary companions, he reached Washington (3 March 1843) only to find that the treaty had been signed, but that the Oregon question had not been included. Whitman, as Spalding's version represents, at once went to work to show the government the value of the land it had deemed worthless, demonstrated to the people the fertility of the soil of Oregon, and the fact that it could be reached by wagon, and then returned at the head of a large body of emigrants. By his daring ride and earnest endeavors Whitman, in this view of the matter, won this great section for the United States and the results of his work were secured by the treaty of 1846. This claim, however, has been the subject of much controversy, and to the satisfaction of some students has been disproved. Whatever its merits, there is no doubt that Whitman's ride (he reached Boston 30 March 1843) resulted in the reversal of the missionary board's purpose to discontinue the southern branch of the mission in which he was engaged; and his work and that of his companions has a historical relation to the American settlement of the Oregon country. Whitman, his wife, and 12 of their companions were massacred by the Cayuse Indians. Consult Nixon, 'Life of Marcus Whitman' (1895); Mowry, 'Marcus Whitman' (1901); and Bourne, 'Essays in Historical Criticism' (1901), in which the Whitman claims are examined and discredited; and Marshall, W. J., 'The Acquisition of Oregon and the Long Suppressed Evidence about Marcus Whitman' (Seattle 1911). See OREGON; OREGON QUESTION, THE.

**WHITMAN, Sarah Helen Power**, American poet: b. Providence, R. I., 1803; d. there, 27 June 1878. She was married to John W. Whitman, a Boston lawyer, was once engaged

to Edgar Allen Poe, afterward writing a defense of him entitled 'Edgar A. Poe and His Critics' (1860); contributed numerous critical articles and poems to periodicals, and was noted for her conversational powers. Her verse was in part collected in the volume 'Hours of Life, and Other Poems' (1853), and fully in the posthumous 'Poems' (1879). 'Fairy Ballads' and some other works were written with her sister, Anna M. Power. Her finest poem, 'A Still Day in Autumn,' has much melody and beauty of expression and retains an honored place in anthologies.

**WHITMAN, Walt** (originally WALTER), American poet: b. West Hills, Long Island, N. Y., 31 May 1819; d. Camden, N. J., 26 March 1892. He was educated in the public schools of Brooklyn, and learned the printer's trade after which he taught in country schools in Long Island. For a brief period he did editorial and reportorial work on newspapers, and in 1847-48 he made an extensive pedestrian tour as a workman through the United States and Canada, subsequently employing himself as a carpenter and builder. His first and chief work, 'Leaves of Grass,' was published by himself in New York in 1855. This thin volume of 94 pages was received, for the most part, with abuse, mainly because of its unconventional metrical style and the freedom with which the poet dealt with moral and social subjects. During the American Civil War, Whitman's brother was wounded on the battlefield, and the poet, who hastened to his aid, remained afterward as a volunteer army nurse at Washington and in Virginia for the years 1862-65. One result of this experience was the small volume 'Drum Taps' (1865), subsequently included with 'Leaves of Grass.' After the war he held a government clerkship in Washington, but the fatigue and mental strain of his labors in the hospitals brought about a severe attack of paralysis in 1873. He was recovering from this when the sudden death of his mother in his presence caused a serious relapse. From this time he resided at Camden, N. J., never securing robust health. During all these years Whitman wrote with the old vigor and freedom of rhythm, but with less of the early crudeness of expression. Though Whitman, like Carlyle and Browning, may be a dangerous and dangerously easy model for imitation, he undoubtedly worked out for himself a style of distinction as notable as theirs. This in itself is a title of fame, or at least a charm against oblivion, even though his literary style ran to extremes and vices. His evolved style was a rhythmic recitative or irregular chant, precursors of which may be found in the English translation of the Psalms and other Biblical poems, in Macpherson's 'Ossian,' and in the later poems of William Blake. These chants vary in movement and seem governed by laws rhythmic rather than metric, which (like the grammar of an unwritten tongue) have never been formulated even by the inventors themselves. They have a peculiar, wild, stirring charm, which is apt, for a time, to make regular verses seem tame and insipid. As to subject, Whitman set himself the Atlantean task of uplifting into the sphere or dominion of poetry the whole of modern life and man, omitting nothing, com-

cealing nothing. His thesis is that of Saint Peter's vision: "There is nothing common or unclean." Hence the logical necessity with Whitman to include the treatment of subjects which in modern society are tabooed as obscene and unmentionable; hence, too, the accusations of indecency, so evident and pertinent from the accuser's point of view, but so futile and irrelevant from that of the accused. Whitman was an idealist who bound himself by a solemn vow to be a thorough-going realist; and his resolute and often successful endeavor to secure this union gave his work its exceptional artistic quality. He was a prince of impressionists in literature. But so hard and high was the task that he set himself, that it is no matter of surprise that he sometimes, if not often, fails, and from heights where he was approaching the sublime, falls perilously near the ridiculous. This is the fate of all artists who strive for the highest things, that their failures — often only apparent — are more easily detected than their solid achievements; hence the contumely and ridicule that a Turner or a Wordsworth, Keats or Shelley suffers at the hands of a clever but uninitiated critic. So it was largely with Whitman; but it is better to approach him in the same spirit that he has shown toward man and nature, that of forever seeking for what was great and good, while outfracting steadily and bravely every stern and refractory reality. As the years roll on, Whitman's work is more highly esteemed. He had the true poetic fire, and was one of those who "talked with angels," and had glimpses of the life beyond. Several writers have contended that he was "illuminated," like Moses and Swedenborg. Besides the two books already mentioned, he published 'Drum-Taps' (1865); 'Memoranda During the War' (1867); 'Democratic Vistas' (1870); 'Passage to India' (1870); 'After All, Not to Create Only' (1871); 'As Strong as a Bird on Pinions Free' (1872); 'Two Rivulets' (1873); 'Specimen Days and Collected' (1883); 'November Boughs' (1885); 'Sands at Seventy' (1888); and 'Good!ye, My Fancy' (1892).

The *Conserverator*, of Philadelphia, is the organ of Whitman study. Consult 'Autobiographia,' selected from the poet's writings (1892); Bazalgette, Leon, 'Walt Whitman - The Man and the Artist' (Garden City, N. Y., 1919); Burroughs, 'Whitman as Poet and Person' (1870); Buche, authorized 'Life' (1883); Burroughs, 'Whitman: A Study' (1896); Harrod, Thomas B., (ed.) 'Letters of Anne Gilchrist and Walt Whitman' (1918); O'Connor, 'The Good, Gray Poet' (1860); Dowden, 'Snakes in Literature' (1878); Symonds, 'Essays, Speculative and Suggestive' (Vol. II, 1899); Slav, 'Walt Whitman, Bibliography' (New York, 1910).

**WHITMAN**, Mass., town in Plymouth County, on the New York, New Haven and Hartford Railroad, about seven miles east of Brockton and 20 miles south by east of Boston. The chief manufacturing establishments are boot and shoe factories, paper and wood box factories, tuck and nail works and steel shank factory. Whitman has 65 manufacturing establishments, employing about 2,500 persons, with annual products of over \$6,000,000. It has

seven churches, public schools and a library. There are two banks, one na one savings bank. The government is tered by annual town meetings. The originally a part of Abington, but w in 1875 and incorporated as South In 1886 the present name was adop 7,292.

**WHITMAN COLLEGE**, located Walla, Wash. It was founded by C as a memorial to Marcus Whitman was chartered in 1859 as Whitman but was not open to students till 186 the courses were extended, the stand and a new charter obtained in 1883 the name was changed to Whitma Women are admitted on equal terms students. The organization includes to the College Department, the Co of Music and the Academy. The c of the degrees of bachelor of art; of letters, bachelor of science and b music. Certain studies, including B figure, are required for all courses required for the H.B. degree, French for the B.L. and B.S. degrees, and work in theory of music, history of i mony and counterpoint for the mu Each student by the end of the fr must elect a major study in which a work must be done; the major for tl gree must be in mathematics or a sci rest of the required number of hou electives. Courses in pedagogy are i the curriculum. Practical music wor count toward a degree in the above courses; but in the conservatory the bachelor of music is conferred on st hold a bachelor's degree and comple ular music course. There are 20 s and one loan fund; students are aid ing employment. The students main tian associations, literary societies a torical association, glee clubs, athlet ions and a general organization kn "Associate Students"; the college i with the Inter-Collegiate Debating , and the Inter-Collegiate Athletic . The campus consist of 27 acres near of the city and includes a small buildings include the Whitman Merr ings Hall (men's dormitory), Key and Prentiss Hall (women's dormitor ciation Hall, the conservatory and t sium. The library in 1917 contai volumes; the students numbered 49 productive funds totaled \$684,044.

**WHITMARSH, Hubert Phel** journalist; b. Macho, province o 10 Aug. 1803. He was a d; New York and Boston in 1887. in the latter year became the tive of the *Century* in Cuba. quently went to the Philippines fo look and in 1900-01 was governor c P. I., resigning in the last-named yea published 'The World's Rough Ha Golden Talisman'; 'Mysterious Voy Dajabon'; 'The Young Pearl Divers

**WHITNEY**, hwit'ni. **Adelin** Train, American author; b. Boston Sept. 1824; d. Milton, Mass., 21 M

Eli Whitney

married to Seth D. Whitney of Milton, 1843. Although a frequent contributor to different periodicals during her earlier real literary career did not begin until her best work was done in the two following decades. Her writings, which are for young people, are wholesome in tone and retaining in style, and include, among others, 'Footsteps on the Seas, a Poem' (1862); 'Boys at Chequasset' (1862); 'Faith's Girlhood,' which first brought her general notice (1863); 'A Summer in Lesdithwaite's Life' (1866); 'Patience Outings' (1868); 'Hitherto: A Story of Days' (1869); 'Real Folks' (1871); 'verse' (1872); 'Sights and Insights' (1872); 'Bonnyborough' (1885); 'Bird Talk,' (1887); 'A Golden Gossip' (1890); 'Letters to Girl Friends' (1897), etc.

**WHITNEY, Anne,** American sculptor and Watertown, Mass., September 1821; d. 1915. She contributed to magazines and wrote considerable verse of high quality in 1859 in a volume of 'Poems.' In 1860 she began work as a professional sculptor, at a studio at Watertown, whence, after years of study abroad, it was transferred to Boston. Among her works are the figure of Samuel Adams for the Capitol at Boston, a bronze replica of which stands in a square, Boston; one of Lief Erikson in a replica in Milwaukee, Wis.; and signs and studies, including 'Roma,' a gilded copy of which was exhibited at the 1893 Exposition.

**WHITNEY, Asa,** American inventor and tinner: b. Townsend, Mass., 1 Dec. 1791; d. Philadelphia, 4 June 1874. As a boy he learned at the blacksmith's trade, also became a tinner, and afterward manufactured machinery in Vermont and at Brownsville, N. Y. He was appointed master machinist of saw and Hudson railroad shops, and later became superintendent of the same in 1839-41 he was a State canal commissioner in New York, and in 1842 removed to Philadelphia, where he entered into partnership with the Baldwin in the building of locomotives.

In 1847 he perfected a process for casting iron carwheels, and began to manufacture them extensively. By his further inventions in carwheels, etc., he did much to increase the convenience and safety of railroads and travel. He left \$50,000 to the State of Pennsylvania to found a chair in mechanical engineering.

**WHITNEY, Caspar,** American journalist: b. Baltimore, Md., 2 Sept. 1862. He graduated from Saint Mathew's College, spent several years in traveling and acting as correspondent for *Harper's* during much of the time and writing on sports. For five years he was editor of and later of *Outdoor America*. His articles include 'A Sporting Pilgrimage'; 'Ones to the Barren Grounds'; 'Hawaiian'; 'Jungle Travels and Jungle People'; 'Wing Road,' etc.

**WHITNEY, Eli,** American inventor: b. Boston, Mass., 8 Dec. 1765; d. New Haven, Conn., Jan. 1825. He was graduated at Yale while there having paid his expenses

partly by teaching, partly by mechanical labor. He went to Georgia as a teacher, but finding a patron in the widow of General Nathaniel Greene, of the Revolutionary army, he resided on her estate and studied law. The cotton culture at this period, especially that of the best kind, the green-seed cotton, was limited by the slow and difficult work of separating the cotton from the seed by hand. Whitney set to work to remedy this by inventing a machine, but worked under great disadvantages, for he had to make his own tools. Reports of his success prompted some lawless people to break into his workshop and steal his machine, and get others made before he could secure a patent. He formed a partnership with one Miller in 1793 and went to Connecticut to manufacture cotton gins; but the lawsuits in defense of his rights carried off all his profits and \$50,000 voted him by the State of South Carolina. Finally in 1798 he got a government contract for the manufacture of firearms, and was the first to effect the division of labor by which each part was made separately. He made a fortune by this manufacture, carried out with ingenious machinery at Whitneyville, Conn.; while he received little credit for the perfection of the gin, one of the most important of the whole series of inventions connected with the cotton manufacture. See COTTON; COTTON CULTIVATION IN THE UNITED STATES.

**WHITNEY, Gertrude Vanderbilt** (Mrs. HARRY PAYNE WHITNEY), American sculptor, daughter of Cornelius Vanderbilt, 1843-99 (q.v.); b. New York City. She was married to H. P. Whitney, son of William C. Whitney (q.v.), in 1896, is prominent socially and has gained a considerable reputation as a sculptor. She organized the Society of Friends for Young Artists; and during the European War she maintained a hospital at Neuilly, France, for which service she received a gold medal from the French Foreign Office in 1915. She designed the 'Titanic Memorial' for Potomac Park, Washington, D. C.; the 'Aztec Fountain,' Pan-American Union, Washington; 'The Fountain of El Dorado' (exhibited at San Francisco, 1915), etc.

**WHITNEY, Henry Howard,** American military officer: b. Glen Hope, Pa., 25 Dec. 1866. He was graduated from West Point in 1892, and was on special duty at the War Department in 1896-98. In the last-named year, under orders from the Secretary of War, he disguised himself as an English sailor, communicated with General Gomez, and made a military reconnaissance of the island of Porto Rico, thereby gaining the information upon which General Miles based the campaign on that island. He was captain of volunteers in 1898-99, served through the Spanish War as captain and assistant adjutant-general on the staff of General Miles, and in 1899 was appointed lieutenant. He accompanied General Miles in his tour around the world in 1902-03, and since 1911 has been stationed at Mindanao, P. I.

**WHITNEY, Sir James Pliny,** Canadian statesman: b. Williamsburg, Ontario, 2 Oct. 1843; d. 24 Sept. 1914. He was called to the bar of Ontario in 1876, and engaged in practice at Morrisburg, Ontario. He was elected to the Ontario legislature in 1888, where he became

the leader of the Conservative Opposition; and from 1905 until his death he was Premier of Ontario. He was knighted in 1908.

**WHITNEY, Josiah Dwight**, American geologist, brother of W. D. Whitney (q.v.): b. Northampton, Mass., 23 Nov. 1819; d. Lake Sunapee, N. H., 18 Aug. 1896. He was graduated at Yale in 1839, and spent the years 1842-47 in study in Europe, and then explored, with J. W. Foster, the Lake Superior region. Their 'Synopsis' of the explorations was published in 1849 and their 'Report' on the geology, 1850-51. He was appointed State chemist and professor in the Iowa State University in 1855 and State geologist of California in 1860. He labored on the survey of that State till 1874, publishing his 'Geological Survey of California' (1864-70). In 1865 he was appointed to the chair of geology at Harvard. Among his publications not already named are 'The Metallic Wealth of the United States' (1854); 'Yosemite Guidebook' (1869); 'Contributions to American Geology' (1880); 'Studies in Geographical and Topographical Nomenclature' (1888). The highest peak of the Sierra Nevada was named Mount Whitney (q.v.) in his honor.

**WHITNEY, William Collins**, American capitalist and politician: b. Conway, Mass., 15 July 1841; d. New York, 2 Feb. 1904. He was graduated at Yale in 1863, and at the Harvard Law School in 1865; studied law with Abraham K. Lawrence in New York, and was admitted to the bar in that city. He took an active part in the organization of the Young Men's Democratic Club, and in the proceedings against the "Tweed Ring"; served as corporation counsel of the city in 1875-82, thoroughly reorganizing the law department; and was secretary of the navy in the Cabinet of President Cleveland from 1885 to 1889. In this position he accomplished much in the development of plans for strengthening the naval service, and the "new navy" owes its subsequent increase in considerable part to his progressive policy. He did effective work for the election of Grover Cleveland as governor of New York in 1882, and as President in 1884, and again in 1892, when he was manager of the Democratic campaign. He declined to enter the Cabinet again, preferring to pursue his business career, in which his interests had grown to great proportions. One of his largest enterprises was that which resulted in the consolidation of the various street railway lines in New York City. The Metropolitan Street Railway system was mainly organized by him, and he was a director in many corporations and societies. He was also a man of recreations, was especially interested in the breeding and training of horses, and became the recognized leader of the American turf, for the elevation of which to higher levels of sportsmanship he successfully strove. At the time of his death he was one of the largest landowners in the East, his holdings being in several States, and including a game preserve of 16,000 acres in the Adirondacks. While his main residence was in New York, he also maintained others on his various estates, North and South, as well as a house in London. He left two sons, Harry Payne Whitney and Payne Whitney.

**WHITNEY, William Dwight**, American philologist, brother of J. D. Whitney (q.v.): b.

Northampton, Mass., 9 Feb. 1827; d. New Haven, 9 June 1894. He was graduated from Williams College in 1845, studied at Yale in 1849-50, and then went to Germany, where he continued his philological and Sanskrit studies under Bopp at Berlin and Roth at Tübingen. He was appointed to the professorship of Sanskrit at Yale in 1854, and in 1870 he received in addition the chair of comparative philology, posts which he retained till his death. In 1856 he published, with Roth, an edition of the Atharva-Veda Sanhita, and in 1862 issued at New Haven an edition, with translation and notes, of the 'Atharva-Veda Prātiçākhyā'. His 'Language and the Study of Language' (1867) was an admirable exposition of the main principles of comparative philology. His other published works include 'A Compendious German Grammar' (1869); 'A German Reader' (1869); an edition of the 'Taittiriya-Prātiçākhyā' (1872), for which he was awarded the Bopp medal of the Berlin Academy; 'Oriental and Linguistic Studies' (1872); 'The Life and Growth of Language' (1875); 'Essentials of English Grammar' (1877); 'A Sanskrit Grammar' (1879); 'The Roots, Verb Forms, and Primary Derivatives of the Sanskrit Language' (1885), a supplement to the grammar; 'A Practical French Grammar' (1886), etc. He was a contributor to Böhtlingk and Roth's great 'Sanskrit Dictionary' (1853-75) and editor-in-chief of 'The Century Dictionary of the English Language' (1889-91). He was elected a member of the American Oriental Society in 1850 and wrote more than half of the contents of Vols. 6-12 of the 'Journal' of that society. For a complete bibliography of his work, consult the 19th volume of the 'Journal of the American Oriental Society' (1897).

**WHITNEY, Willis Rodney**, American chemical engineer: b. Jamestown, N. Y., 22 Aug. 1868. He was graduated at the Massachusetts Institute of Technology in 1890 and took his Ph.D. at the University of Leipzig in 1894. He was appointed non-resident assistant professor of theoretical chemistry at the Massachusetts Institute of Technology in 1904, and non-resident professor in 1908. Since 1904 he has been director of the research laboratory of the General Electric Company, Schenectady, N. Y. Among other results of his research work may be mentioned the perfecting of the metallic electric lamp filaments and the development of wrought-tungsten. He was president of the American Chemical Society in 1910 and received its Willard Gibbs Medal in 1916. He was also president of the Electrochemical Society in 1911; and was appointed to the Naval Consulting Board in 1915. He is author of many papers in technical magazines and translator of Le Blanc's 'Electro-Chemistry' (1896).

**WHITNEY, Mount**, a peak of the Sierra Nevada, in the southeastern part of California; altitude, 14,522 feet. It is the highest elevation in the United States, outside of Alaska. On the east side the slope is precipitous, rising abruptly from Owens Valley about 11,000 feet. In 1881 Prof. S. P. Langley remained for some time on the summit, making daily observations on the solar heat.

**WHITNEYITE**, a metallic mineral, containing 88.4 per cent of copper and 11.6 per cent of arsenic and having the formula  $Cu_{10}As_2$ . It is

only massive, its structure being very anular. It is malleable, has a hardness and specific gravity of about 8.5. Its is pale reddish-white, tarnishing quickly ronze or nearly black. It has been re- l as a rare mineral until discovery of quantities in the Mohawk mine, Michigan, it is now a valuable ore of copper.

**HITON, James Morris**, American Con- onal clergyman: b. Boston, Mass., 11 April He was graduated at Yale in 1853 and received the degree of Ph.D. He became of the Hopkins Grammar School in New , Conn. (1854-64) and was a Congrega- pastor in Lynn, Mass. (1865-75) and from 3 at Williston Seminary, Easthampton,

Later he was Congregational pastor in k, N. J., and New York (1879-91) and th, N. J. (1898-1901). Since 1896 he has in the editorial staff of the *Outlook* and ) was elected chairman of the New York Conference of Religion. Among his pub- works are several school textbooks in and Latin and the following: 'Select is of Lysias' (1875); 'Is Eternal Punish- endless?' (1876); 'Beyond the Shadow'; l of the Resurrection' (1881); 'The ion of Revelation' (1885); 'The Divine ction' (1885); several volumes of ser- preached in Great Britain (1887-89); a Patri, Our Talks about the Trinity'; 'Reconsiderations and Re-enforcements'; 'Miracles and Supernatural Religion'; 'Interludes, Ethical, Social, Theolog- 1910); 'Getting Together, Essays by s in Council' (1913).

**HITRIDGE, Frederick Wallingford**, can lawyer: b. New Bedford, Mass., 8 1852; d. New York, 30 Dec. 1916. He aduated at Amherst College in 1874 and : Columbia University Law School in He was admitted to the bar in 1879 and d in practice in New York, where he became senior partner in the law firm dge, Butler and Rice. He was also presi- of several electric railway lines in New and its surrounding suburbs. He was r on administrative law at Columbia 'sity in 1883-94. In 1906 he was special States Ambassador to Spain to attend onation of King Alphonso XIII. He is of many papers on politics and econom- d of 'One American's Opinion of the an War: An Answer to Germany's Ap- (1914).

**HITSIDE, hwit'sid, Samuel Marma-** American military officer: b. Toronto, 9 Jan. 1839; d. 1904. He entered the States army in 1858; served through the ar, was brevetted major in 1865 and in as appointed captain. He was afterward d for more than 25 years in the Indian on the Western frontier, where he cap- Big Foot and his 400 Sioux warriors in ber 1890; and commanded his regiment battle of Wounded Knee on the follow- y. He was promoted lieutenant-colonel ; was in command of the Fifth United cavalry during the Spanish-American nd was placed at the head of the Depart- of Santiago and Puerto Principe, Cuba, uary 1900. He was promoted brigadier- l of volunteers in 1901, receiving that

rank in the regular army in 1902, and in the same year was retired from active service.

**WHITSITT, hwit'sit, William Heth**, American Baptist clergyman and educator: b. Nashville, Tenn., 25 Nov. 1841; d. 1911. He was graduated from Union University, Mur- freesboro, Tenn., in 1861, served in the Con- federate army, 1862-65, and was pastor of Mill Creek Church, Nashville, 1865-66. He subse- quently studied at the University of Virginia, the Southern Baptist Theological Seminary, Louisville, Ky., and at Leipzig, and became pastor of a Baptist church in Albany, Ga., in 1872. He was professor in the Southern Bap- tist Theological Seminary, 1872-95, president of that institution, 1895-99, and was also pro- fessor of philosophy at Richmond College, Va., after 1901. He has published 'History of the Origin of Infant Baptism'; 'Origin of the Disciples of Christ'; 'A Question in Baptist History' (1897).

**WHITSON, John Harvey**, American nov- elist: b. Seymour, Ind., 28 Dec. 1854. He was admitted to the Indiana bar in 1876, but after practising his profession for a time turned to journalism. He has published 'The Young Ditch Rider and Other Stories' (1899); 'Bar- bara, a Woman of the West' (1903); 'With Fremont the Pathfinder' (1903); 'The Rain- bow Chasers' (1904); 'A Courier of the Emp- pier' (1904); 'Campaigning with Tippecanoe' (1904); 'Justin Wingate, Ranchman' (1905); 'The Castle of Doubt' (1906).

**WHITSUNDAY**, the seventh Sunday after Easter; a religious festival in commemoration of the descent of the Holy Spirit on the day of Pentecost. The name was derived from the white garments worn on that day by candidates for ordination and children presented for bap- tism. The older name was Pentecost. See PENTECOST.

**WHITTEMORE, hwit'ë-môr, Amos**, American inventor: b. Cambridge, Mass., 19 April 1759; d. West Cambridge (now Arlington), Mass., April 1828. He worked for some years as a gunsmith, and finally formed a co- partnership with one of his brothers and several other persons for the manufacture of cot- ton and wool cards. He had not been long en- gaged in this business before he invented a machine for puncturing the leather and setting the wires, a work previously performed by hand. In experimenting for this invention he met with great difficulty in bending the wires to a given angle after they were finally fastened in the leather, and was on the point of giving up the attempt when in a dream he discovered a method of effecting it. The invention was patented in the United States in 1797, and Whittemore went to England to secure his rights there, but was unsuccessful. In the United States the patent was sold for \$150,000; but afterward his brother Samuel Whittemore repurchased it, and carried on the business. Amos Whittemore devoted his last years to the invention of an orrery, in which every planet was to describe its own orbit, but did not live to complete it.

**WHITTEMORE, Thomas**, American Uni- versalist clergyman: b. Boston, 1 Jan. 1800; d. Cambridge, Mass., 21 March 1861. He studied for the ministry under the Rev. Hosea Ballou,

in April 1821; was settled as the Universalist minister at Milford, Mass., and the next year removed to a church in Cambridgeport, Mass. He resigned in 1833, but resided in Cambridge for the remainder of his life. Early in his ministry he was joint editor of the *Universalist Magazine*, and in 1828 commenced the publication of the *Trumpet*, a Universalist newspaper in Boston, of which he was sole editor and proprietor for nearly 30 years. He was also president of the Cambridge bank and of the Vermont and Massachusetts Railroad, and represented Cambridge repeatedly in the State legislature. He published 'A History of Universalism' (1830; enlarged 1860); 'Notes and Illustrations of the Parables' (1832); 'Songs of Zion' (1836); 'Plain Guide to Universalism' (1839); 'Life of Hosea Ballou' (1854-55), etc. Consult his 'Autobiography' (1859).

**WHITTIER**, hwit'-er, **John Greenleaf**, American poet: b. Haverhill, Mass., 17 Dec. 1807; d. Hampton Falls, N. H., 7 Sept. 1892. A Quaker, he labored in boyhood on the farm made celebrated by 'Snowbound,' and received but little formal education, though he contrived by working at shoemaking and teaching to pay for two periods of six months at Haverhill Academy in 1827-28. The acceptance of a poem from him in 1826 for the Newburyport *Free Press* led to a lifelong friendship with its editor, William Lloyd Garrison (q.v.). His fame had become so firmly established as a poet, that most people forget his long career as an editor and reformer. He edited the *American Manufacturer*, a weekly concerned chiefly with mechanics, the industries and agriculture, in Boston in 1829, and in the following year the *Haverhill Gazette*. During 1830-32 he conducted the *New England Review*, which G. D. Prentice (q.v.) had brought into some prominence, at Hartford, Conn., and to this time belong his first independent publications, 'Legends of New England' (1831), and 'Moll Pitcher' (1832). In 1833 he issued 'Justice and Expediency,' an anti-slavery pamphlet and acted as a secretary of the anti-slavery convention at Philadelphia, and a member of the committee which drafted the "declaration of principles." He sat in the Massachusetts legislature in 1835, and in the following year sold his farm and removed to Amesbury, some eight miles northeast of Haverhill, where he chiefly resided for the rest of his life. In 1836 he became secretary of the Anti-Slavery Society, and in 1837 there appeared a volume of 'Poems Written During the Progress of the Abolition Cause in the United States.' With that cause he was now thoroughly identified. At Concord, N. H., he, with George Thompson (q.v.), was mobbed during the latter's lecturing tour. Whittier edited the *Pennsylvania Freeman* in Philadelphia during 1838-40, and in the first of these years his office was sacked and burned by a mob. In 1844-45 he edited the *Middlesex Standard* in Lowell, and during 1847-60 was corresponding editor of the *National Era*, a Washington paper, sometimes writing half a dozen columns weekly of general articles and reviews. He also contributed to the *Atlantic Monthly* from its foundation in 1857. His poem, 'A Word for the Hour' (January 1861), shows that he shrank from the Civil War and was prepared to let the Southern

States secede. He hailed the end of the war and of slavery with delight, and did his utmost to induce the North to welcome back the South in the most generous spirit. His publications, after those above mentioned, include the following: 'Mogg Megone' (1836); 'Poems' (1838); 'Lays of My Home and Other Poems' (1843); 'The Stranger in Lowell' (1845); 'Supernaturalism in New England' (1847); 'Leaves from Margaret Smith's Journal' (1849), an imaginative description of early New England, and 'Old Portraits and Modern Sketches' (1850), all four collected from the 'Era'; 'Voices of Freedom' (1846); 'Songs of Labor, and Other Poems' (1850); 'The Chapel of the Hermits, and Other Poems' (1853); 'Literary Recreations and Miscellanies,' also gathered from the 'Era' (1854); 'The Panorama, and Others Poems' (1856); 'Home Ballads and Poems' (1860); 'In War Time, and Other Poems' (1864); 'National Lyrics' (1865); 'Snowbound: a Winter Idyl' (1866); 'The Tent on the Beach, and Other Poems' (1867); 'Among the Hills, and Other Poems' (1869); 'Miriam, and Other Poems' (1871); 'The Pennsylvania Pilgrim, and Other Poems' (1872); 'Hazel Blossoms' (1875); 'Mabel Martin: a Harvest Idyl' (1875); 'The Vision of Echard, and Other Poems' (1878); 'The King's Missive, and Other Poems' (1881); 'The Bay of Seven Islands, and Other Poems' (1883); 'Saint Gregory's Guest, and Recent Poems' (1886), and 'At Sundown' (1892), a posthumous volume. The Riverside edition of his works, both in prose and in verse, carefully revised and annotated by himself, appeared at Boston in 1888-89. The most complete edition of the poems is the one-volume Cambridge edition (1895). Whittier was long interested in politics, though his active participation largely ceased with the development of anti-slavery opinion in the North. His services to the cause of anti-slavery were important. He wrote numerous occasional poems celebrating or denouncing incidents and events of the conflict, the best known being the 'Ichabod' verses, "the most powerful that he ever wrote," reliking the defection of Webster from the anti-slavery principles in the 'Seventh of March' speech. Opposed to the Civil War, he insisted when it was begun, that slavery was the vital question, and during its progress contributed largely to the small quantity of valuable poetry that it evoked. Subsequently he devoted himself to presenting in narrative and ballad poems the legends, traditions and history of colonial America, particularly New England; to describing, as he did notably in 'Snowbound,' rural scenes and conditions, many of which have passed into history, and to writing several lyrics which appear in the collections of many denominations. His work had been criticized for its inequality and faulty rhymes, and also somewhat for its moralizing tendency. Much of his verse does reveal a certain want of compression and verbal selections, due principally to the fact that it was written with a readiness approaching improvisation. To object to his moralizing tendency is simply to object to the point of view of one who was originally and strongly a reformer. His leading characteristics are a fine simplicity, a convincing quality and what Lowell styled as his "genial piety."

smopolitan than Longfellow, but has been ranked as not greatly a poet. Consult the biographies (1875; new ed., 1883); Kennedy (1893); Pickard (1894; the author and Letters'); Barton (1900; aphies'), and Carpenter, G. R. idation; though it is treated as itical 'Lives' by Lysons (1860) id Rice (1881; 2d ed., 1894). on, 'Popular Tales and Fictions' eatley's edition (for the Villon 'History of Sir Richard Whit- H. (1885).

**WHITTLESEY**, hwit'l-sì, **Charles**, Ameri- can geologist: b. Southington, Conn., 4 Oct. 1808; d. Cleveland, Ohio, 1886. He was gradu- ated from West Point in 1831, served in the Black Hawk War of 1832 and resigned from the army in that year. He was admitted to the bar and engaged in law practice at Cleve- land, where he was on the editorial staff of the *Herald* in 1836-37, and in 1837-38 was engaged in the Ohio State geological survey. He was occupied in making a mineralogical and geologi- cal survey of the Lake Superior and upper Mississippi regions for the United States gov- ernment in 1847-51, and in 1858-60 was attached to the Wisconsin geological survey. On 17 April 1861 he was appointed assistant quar- ter-master-general in the staff of the governor of Ohio, and in the western Virginia campaign served as chief engineer of the Ohio troops. He was appointed colonel in August 1861 and was subsequently chief engineer of the Depart- ment of the Ohio. He led his regiment at the battle of Fort Donelson and at the battle of Shiloh was in command of a division. Failing health compelled his resignation in 1862 and he resumed his surveys in the Lake Superior and upper Mississippi regions. He was one of the founders in 1867 of the Western Reserve Historical Society of Cleveland and was for many years its president. His writings include more than 200 titles. Among them are 'De- scription of Ancient Works in Ohio' (1851); 'Ancient Mining on the Shores of Lake Su- perior' (1863); 'Early History of Cleveland and Vicinity' (1867), etc.

**WHITTREDGE**, hwit'rèj, **Worthington**, American artist: b. Springfield, Ohio, 22 May 1820; d. 1910. He studied art in Cincinnati, worked there as a portrait-painter 1842-49, later went to Europe and studied under Andreas Achenbach at Düsseldorf, also in Paris, Bel- gium, Holland and Rome, returning to the United States in 1859, to become noted as a landscape painter, his chief subjects being drawn from American scenery. Accompanying General Pope on a tour of inspection at the West in 1874, he sketched many Rocky Moun- tain views. He was president of the National Academy of Design in 1875-76. His chief works include 'House on the Hudson River' (1863, in the New York Public Library); 'Old Hunt- ing Ground' (1864); 'View of the Rocky Mountains from the River Platte' (1868); 'Trout Brook' (1875); 'Camp Meeting' (1906, in the Metropolitan Museum), etc.

**WHITWORTH**, hwit'wérth, **SIR Joseph**, English mechanical engineer: b. Stockport, 21 Dec. 1803; d. Monte Carlo, Italy, 22 Jan. 1887. He worked as a mechanic in Manchester and London, discovered the method of making a truly plane surface, and in 1833 established himself as a tool-maker at Manchester. Be- tween 1840 and 1850 he developed his measur- ing-machine, by means of which he elaborated his standard system of uniform measures and gauges which was found by engineers to be of great usefulness. One of his devices which proved to be of much immediate service was that of a uniform system of screw-threads. He made many experiments in connection with rifles, and in 1857 perfected a hexagonal-bar- reled rifle of great range, accuracy and pene-

trative power, highly excelling the Enfield, then largely in use. It was not accepted at the time by the War Department, as being of a calibre too small (4.5) for a military weapon; though in 1869 the War Office declared that a weapon of such calibre would appear to be the most suitable. He was equally successful in the building of cannon, but his rifled gun with a 250-pound shell and a six-mile range, was rejected by the ordnance board in 1865, greatly to the detriment of British ordnance. His invention of compressed cast steel for ordnance was an important one, and came into general use. His works at Manchester were converted into a limited liability company in 1874, and in 1897 united with the Elswick works, established by Sir William Armstrong (q.v.). His fortune was devoted to the endowment of 30 scholarships in mechanics and to the furthering of charitable and educational work. He was made a baronet in 1869. Among his writings were 'The Industry of the United States in Machinery, Manufactures and Useful and Ornamental Arts' (1854) and 'Miscellaneous Papers on Mechanical Subjects' (1858). Consult the memoir in the 'Proceedings' of the Institution of Civil Engineers, Vol. XCI (1887-88).

**WHITWORTH GUN.** See **ORDNANCE**.

**WHITWORTH SCHOLARSHIPS**, certain scholarships established in England in 1869 by Sir Joseph Whitworth, to encourage the cultivation of combined theoretical and practical skill in the industrial arts of mechanics and engineering. They were placed by the founder under the charge of the English council of education, and are open to be competed for by any young man not 26 years complete, and who has been engaged in handicraft in the workshop of a mechanical engineer for at least three years. There are now four scholarships annually competed for of the value of \$500, tenable for three years, besides exhibitions tenable for one year, value \$250 and \$400.

**WHOLE FAMILY PROTECTION.** See **INSURANCE, FRATERNAL**.

**WHOOPEE**, the whooping swan. See **SWAN**.

**WHOOPIING-COUGH.** See **HOOPING-COUGH**.

**WHOOPIING CRANE.** See **CRANE**.

**WHORTLE-BERRY.** See **VACCINIACEÆ**.

**WHYDAH**, hwi'd'ā, French West Africa, a seaport town of Dahomey, on a lagoon communicating with the Bight of Benin, about 70 miles south of Abomey. It has a considerable trade in palm-oil. Pop. about 15,000.

**WHYDAH-BIRD, WHIDAH-BIRD, or WIDOW-BIRD**, a weaver-bird (q.v.) of the West African subfamily *Iriduina*, in which the tail-feathers are greatly prolonged and modified. The paradise whydah-bird is brownish-black, the head, chin and throat being black and the neck encircled by a brown collar. The under parts are pale brown. The tail is long and the two central feathers are elongated and possess broad webs at the tip and a slender shaft, while the two next feathers are about 11 inches long and are broadly webbed. The other tail feathers are set vertically. This species attains a length of five or six inches, exclusive of the tail feathers.

The nest is said to be ingeniously made of cotton fibres and to be divided into two compartments, in one of which the female sits on the eggs, the other being occupied by the male. The shaft-tailed whydah-bird (*V. regia*) is colored a rusty red on the head and the back of the head and crown being black. The average length of this species is nine or nine inches, and the four central feathers are elongated, but consist each of the bare shaft or quill only, a slight web existing at the tip. Consult Newton, 'Dictionary of Birds' (New York 1896).

**WHYMPER**, hwi'm'pēr, Edward, F.R.S., author and traveler: b. London, 27 April 1811. He was educated privately, and in 1831 was sent by a London firm to make sketches of Alpine peaks. He ascended Mount Pelvoux in the French Alps in 1861, the Pointe des Neiges in 1864 and in 1865 the Matterhorn. He discovered northern Greenland in 1867 and in 1872 made valuable discoveries in evidences of a previous abundant rich vegetation there, his collection of specimens being now a part of the collection of the British Museum. In 1879-80 he explored the Andes in Ecuador, discovered the Aconcagua glaciers, and succeeded in ascending the mountain borazo, a feat which Humboldt attempted but had failed to accomplish. In 1901 he explored the mountains of Canada, ascending Mount Mealy and making investigations in the region of the "Great Divide." His publications include: 'Scrambles Among the Alps in the Years 1861-62' (1871); 'Travels Among the Great Mountains of the Equator' (1892); 'Zermatt and the Matterhorn' (1897), and 'Chamonix and Blanc' (1896). The two latter are reprinted almost every year for sale to tourists.

**WHYTE, Alexander**, clergyman of the Free Church of Scotland: b. Kirriemuir parish, Scotland, 13 Jan. 1837. His education was received at the University of Aberdeen at New College, Edinburgh. He was a minister of Free Saint John's, Glasgow, 1860-70; assistant minister, 1870-73 and 1873-1909 of Free Saint George's, Edinburgh. Since 1909 he has been professor of New Testament Literature and principal of New College, Edinburgh. He is the author of 'A Commentary on the Shorter Catechism' (4 series, 1893-1903); 'Samuel Rutherford and some of his correspondents' (1894); 'Jacob Behmen; An Appreciation' (1894); 'Lancelot Andrewes; Private Devotions' (1895); 'Four Treatises' (1895; later ed., 1910); 'Bible Characters' (6 vols., 1896-1902); 'Saint Paul: An Appreciation' (1897, 1910); 'Father of the Greek Church' (1898); 'Sir John Browne: an Appreciation' (1898); 'Cicero and Characteristics of William Law' (1901); 'Newman: an Appreciation' (1901); 'Butler: an Appreciation' (1903); 'The Apostle Paul' (1903); 'Walk, Conversation, Center of Jesus Christ Our Lord' (1905); 'The Shepherd, Pilgrim Father and Founder of Harvard' (1909); 'Thirteen Appreciations of Old Time Divines, Mystics, and (1914).

**WHYTE-MELVILLE**, hwi'm'pēr, George John, British novelist: b. Glasgow, Scotland, 19 June 1821; d. Vale of Ayr, 1891.

Berkshire, 5 Dec. 1878. He was educated at Eton and at 18 joined the 93d Highlanders, from which he exchanged in 1846 into the Coldstream Guards. He retired in 1849 with the rank of major, but volunteered for active service in the Crimean War and was appointed major of the Turkish irregular cavalry. The rest of his life was chiefly devoted to fox-hunting and other field sports, and to the writing of novels of fashionable and sporting life. He was killed by the fall of his horse while hunting. The following are among his novels: 'Kate Coventry' (1856); 'Holmby House' (1860); 'The Queen's Maries' (1862); 'Bones and I' (1868); 'Contraband' (1870); 'Sarchedon' (1871); 'Satanella' (1873); 'Rosine' (1875); 'Roy's Wife' (1878); 'Black but Comely' (1879). He also published some volumes of verse, including notable sporting lyrics.

**WIARD, Norman**, American inventor: b. Normandale, Ontario, 1826; d. Reading, Pa., 11 Sept. 1896. In early life he was foreman in a foundry at Bradford, Ontario, where he began experiments in founding ordnance. During the Civil War he was employed by the United States government in the manufacture of ordnance and projectiles, and was frequently called into consultation by the President and Secretary Stanton. After the war he applied himself to experiments and inventions in his special lines; patented a device for preventing the explosion of steam boilers, which he sold to the United States and Japanese governments; he spent two years in Japan in government employ; was for some time a military engineer in that country; and on his return to the United States conducted, near Boston, a series of experiments in gunnery which attracted wide attention.

**WIARTON**, Canada, town in Bruce County, Ontario, on Georgian Bay, 125 miles northwest of Toronto, and on the Grand Trunk Railway. There are manufacturing interests. Pop. 2,266.

**WIBERT**. See **GUIBERT**.

**WIBORG**, vi'börg, or **VIBORG**, Finland.

(1) A town and capital of the government of its own name, on a bay in the Gulf of Finland, 72 miles northwest of Petrograd, with which and with Helsingfors it is connected by railway. It is regularly built in spacious streets; and has the ruins of a fine old castle, situated on an isolated rock in an arm of the sea. A third-class Russian fortress was located here in 1914. It carries on some iron founding and other industries, and has a considerable trade in timber, deals, tar, tallow and fish. The canal that connects the Gulf of Finland, with Lake Saima, starts at Wiborg. In 1918 it was the seat of government of a Red Guard movement. Pop. about 29,329. (2) The government forming the southeastern region of Finland; has an area of 13,530 square miles. Pop. about 400,000.

**WICASSET**, Me., town, port of entry, county-seat of Lincoln County, on the Sheepscot River and on the Maine, Central Railroad, about 48 miles northeast of Portland and 20 miles from the Atlantic. In 1760 the town was incorporated under the name of Pownalboro, and in 1802 it was reincorporated under the present name. Wicasset is a popular summer

resort with some manufacturing interests. There are two banks. Pop. 1,287.

**WICHERN**, vi'h'ern, **Johann Heinrich**, German philanthropist: b. Hamburg, 21 April 1808; d. there, 7 April 1881. He studied theology at Göttingen and Berlin, and then returning to his native town gave himself up to endeavors to improve the condition of the poor and suffering. In the Rauhes Haus (founded 1 Nov. 1833) he established an institution for neglected children, with a training seminary for teachers connected with it, and similar institutions were shortly afterward formed throughout Germany. In 1856 he was appointed councillor of the Prussian Ministry of the Interior, and in 1858 superintendent of all penal and reformatory institutions in the kingdom. His writings include 'Die Innere Mission der Deutschen Evangelischen Kirche' (1849); 'Die Behandlung der Verbrecher und Entlassenen Sträflinge' (1853); 'Der Dienst der Frauen in der Kirche' (1858). Consult *Lives by Oldenburg* (1881-86); *Krummacher* (1882).

**WICHITA**, Kans., city and county-seat of Sedgwick County, in the south central part of the State on the Arkansas River, about half way (216 miles) between Kansas City and Oklahoma City, and on the Atchison, Topeka and Santa Fe, the Chicago, Rock Island and Pacific, the Missouri Pacific and the Saint Louis and San Francisco railroads. It is the northern terminus of the Midland Valley and the Kansas City, Mexico and Orient railroads and the southern terminus of the Arkansas Valley Interurban. Located in the rich Arkansas Valley its chief products are wheat, oats, corn, broom corn, kaffir, alfalfa, cattle, hogs and poultry. These agricultural products have made it one of the largest milling and packing centres in the central part of the United States. There are several factories devoted to the manufacture of breakfast foods and stock foods. Other manufactories of note are foundry and machine products, automobiles, automobile tires, shirt and overall factories, furniture factories, boot and shoe factories, book binderies and printeries, planing mills. The city has a large wholesale and jobbing trade. The wholesale trade amounted to about \$25,000,000 in 1918, the manufacturing to about \$125,000,000. The city is the chief distributing point of the southwest for automobiles, tractors and trucks as well as all kinds of farm machinery. The two daily newspapers have the largest number of readers in the State. Among the principal public buildings are the United States government building, the courthouse, the city hall, the Scottish Rite Masonic Temple, the Forum and Exposition hall (seating 8,000), the Catholic cathedral and the high school. The city can now boast of one of the finest hotels in the southwest. There are about 40 different churches representing half as many different denominations. Other buildings of importance are the Wichita City Hospital, Saint Francis Hospital, the Wesley Hospital, the Wichita Children's Home, the Masonic Home and the Kansas Sanitarium. Among the educational institutions are Friends University (1898), Fairmount College (Congregational), opened 1892, All Hallows Academy (Roman Catholic), two business colleges, three colleges of music

and a beautiful public library. The city has a very efficient motorized fire department, an adequate system of waterworks and a modern sewage system. The natural gas supply is sufficient for domestic use. The park system is the largest and most beautiful in the State. There are 18 State banks and four national banks. Oil was discovered 20 miles east of Wichita in 1914. During the year 1917 the average daily output from this field was 150,000 barrels. The discovery of oil led to the investment of \$30,000,000 in refineries in Wichita. Since April 1917, Wichita has been governed by a board of five commissioners who chose a city manager to execute the laws and ordinances and to appoint the heads of all departments and all subordinate officers. The public schools consist of six years' work in the elementary schools, three years in the intermediate schools, three years in the high school. There are 31 buildings and 375 teachers. The net funded debt is \$1,363,277; the total realty assessed valuation \$85,000,000, which is 85 per cent of the market value. The tax rate per \$100 valuation is \$1.80. Pop. 75,000.

**WICHITA FALLS, Tex.**, city and county-seat of Wichita County, situated in the northern tier of Texas counties, about 20 miles south of Red River, on the Fort Worth and Denver City, the Missouri, Kansas and Texas, the Wichita Valley, the Wichita Falls and Southern, the Wichita Falls and Northwestern and the Wichita Falls and Oklahoma railroads. Wichita Falls is the most important city adjacent to the new and rapidly developing oil fields of Texas. It is only 15 miles from the Burkburnett field, 11 miles from Iowa Park, 26 miles from Electra and is connected with these fields by railroads. It is 85 miles from the Stephens County fields and 100 miles from the Ranger fields. There are 10 oil refineries now operating in Wichita Falls, Burkburnett, Electra and vicinity, with as many more under construction or contemplated. This city is headquarters for the oil fraternity of this entire section. The city has more than 45 manufacturing plants, exclusive of oil refineries, with a total investment of more than \$6,000,000, and an annual gross output of about \$20,000,000. Among the articles manufactured here are motor trucks, window glass, glass fruit jars, sashes and doors, etc. The Wichita Mill and Elevator Company, one of the most complete plants of the kind in the South, costing three-fourths of a million dollars, does an enormous domestic and export business. Wichita Falls is the distributing and jobbing centre of a large section of North Texas and Southern Oklahoma. Wichita Falls has an estimated population (June 1919) of 40,000. The city is growing perhaps more rapidly than any city of the South. While the enormous increase in population in so short a time has added a gigantic task upon the city, facilities are rapidly becoming adjusted to new conditions. A new eight-story hotel to cost approximately \$1,000,000; two 10-story buildings, one six-story building and 30 smaller business buildings are being erected. A bond issue of \$1,500,000 for permanent public highways was voted recently in the county, and this money is to be expended for good roads as rapidly as possible. Nearly \$1,000,000 is to be spent in the near future for additional street

paving and civic betterment. Besides the recent county road bond issue other available road money will bring the total county and city expenditure for highways to about \$3,000,000. It is planned to have the most elaborate and imposing rural highway system in the Southwest. There are five strong, growing banks with total deposits of \$25,000,000 and clearings of \$83,209,758 for the period from 1 Jan. 1919 to 14 June 1919. Total bank deposits for this city are exceeded by only six Texas cities. Annual postal receipts now approximate \$180,000, or an increase of more than 150 per cent in 12 months. The assessed valuation exceeds \$20,000,000, while the real value of the city property exceeds \$50,000,000. Wichita Falls is a city of homes, schools and churches. There are 25 imposing edifices of worship representing all the leading denominations and faiths. Kemp Public Library, a gift to the citizens from one of Wichita Falls' leading builders, is one of the most complete library buildings in the State and contains an excellent selection of the best literature. Wichita Falls has a modern and efficient system of public schools, and \$100,000 was expended in 1919 for additional buildings. The State of Texas is expending \$750,000 in the erection of one of its eleemosynary institutions located on the shore of Lake Wichita about four miles from the city.

HUBERT M. HARRISON,

*Secretary Wichita Falls Chamber of Commerce.*

**WICHITA INDIANS.** One of the southern tribes of the Caddoan linguistic stock of North American Indians whose traditional home was the Wichita Mountains of Oklahoma, near which their reservation now lies. In the first half of the 19th century their principal village was on the north fork of Red River, a short distance below the mouth of Elm Creek, in Oklahoma, but three centuries ago (in 1541) Coronado found them in Kansas, between the Arkansas and Kansas rivers, in what the Spaniards designated the province of Quivira (q.v.). The typical house of the Wichitas is the grass lodge; they were always agriculturists, and formerly practised tattooing, from which custom and from their resemblance to their congeners, the Pawnees, they are called by the French *Lani Piqués*. They are now under the Kiowa agency in Oklahoma, where, with their tribes, the Tawakoni and Waco, they number more than 300.

**WICKER WEAVING AND PRODUCTS.** The predecessor of all arts, the most universal art and the least changing art in the realms of history is wicker weaving. True, there have been changes in the commodities used for weaving and changes in the article made by weaving, but the actual method of weaving wicker strands has passed down from the very earliest days of mankind with marked uniformity. Weaving in its general sense — including that of textiles as well as wicker — is considered by historians and biblical students as the oldest of arts, but when the general subject is studied it is found that wicker weaving even precedes all other processes. Just when it was born and by whom created is impossible to say. Some biblical students contend that Eve, following her great sin, wove a skirt of twigs and leaves through an endowed art. Other equally studious students assert that

per fellow biblical personages learned of weaving by viewing the interlacing of tree limbs and noting the protection therefrom. Still more assert that the same is known by persons through watch-adopting methods used by birds in their nests or spiders and other in-venting their webs. Whatever caused intelligence to grasp the art of weaving is not to be known, but that it is the earliest as an established or accepted fact. Biblical evidences showing an early use of weaving are found in Exodus 2, where it relates that bindings were woven work. The same book, xxxix, that ropes were made by weaving. 2, tells of an ark (basket) being papyrus reed and Moses set adrift in river Nile. Biblical commentaries state that boats, sails, mats and ropes were weaving. There are other references to weaving, thus in-venting the art, so far as wicker is concerned, was well known in those days. Historians, therefore, speak further of weaving although they do not use the word "wicker," which has long been understood, as perfectly proper in reference to all materials used in the manufacture of furniture, baskets and cages. Modern dictionaries define "wicker" as (1) "a pliant rod or twig; osier; (2) a willow wicker; (3) the work of wicker work; (4) a fabric or texture, as a basket woven or platted osiers, twigs; basket work, as a wickerwork." Since the meaning is so broad it is difficult to trace wicker weaving through the many ages to the present although there is a surfeit of written information on this subject. It is known to have been familiar with the art of weaving, for in the history of races there are references to bags, baskets, roofs, floors, etc. And yet with all this and universal use we find that wicker (no textile weaving) has remained as a slow hand vocation in which the work has been woven about a frame. That development has remained unchanged when Marshall B Lloyd of Menominee, invented and put into practical use the method for weaving wicker and a loom which weaves the strands into shapes desired.

**Curiosities.**—Biblical data shows that wicker weaving was done by using twigs and osiers, interlacing them at the ends in just the same manner as modern weavers work with their more modern looms. Then came heavier pieces of wood indicated in 2 Kings xxiii, 7, which men weave hangings from the grove." This means limbs of trees or vines

hanging from trees is unknown although the latter is the accepted version. Exodus ii, 2, specifically states the ark (basket) of Moses was woven of papyrus reed just as were boats, sails and other articles. Mediæval days find the willow branch popular for wicker weaving. It has remained so to the present day although the scarcity of it and the growing demand for woven work in general has made it necessary, as well as wise, for manufacturers to turn to other forms of wicker. Rattan has been most generally used in making wicker articles during recent years. It is a vine growing in India, China, South Africa and elsewhere in the Orient. It was first used as ballast for vessels returning from the Orient. When the rattan reached America it was burned as firewood or waste. A man named Wakefield, during the days of the hoopskirt, found that rattan would lend itself to the manu-

WICKER BABY CARRIAGE OF THE CLOSING YEARS OF THE 19TH CENTURY.

The running gear is practically the same as that of to-day. The body is woven loosely of flat reed and with as little wicker-work as possible because of the extreme cost of hand weaving.

facture of hoops. This led to its becoming prominent in the manufacture of woven furniture and bodies for baby carriages. Rattan is usually known as reed when used for these purposes. The rattan vine is harvested by natives, then cured and classified as to size and texture. The bark is removed and treated, thus becoming "cane" and used most extensively as seats for chairs, davenport and the like. The wood part of the rattan vine inside the bark is also treated and the finished product is known as "reed." While being woven, reed is kept in water so as to make it pliable. If it is not soaked the reed will not bend without breaking, and despite its extensive use the article gives only limited satisfaction owing to its brittleness. The most recent form of wicker is a fibre made from paper. Just whether it

should be classified as a textile or wicker has not been established. It is manufactured much like a textile (see TEXTILE INDUSTRY) and is used very extensively as a wicker and a textile. It, however, quite naturally fits in under the wicker classification. The lack of willow and the dissatisfaction over reed has long caused baby carriage, furniture and basket makers to seek a new article. The World War of Europe, perhaps, had most to do with the discovery of paper and its adaptability to tex-

MODERN WICKER BABY CARRIAGE.

It is woven of wicker fibre made on the Lloyd Loom. Note the fineness of the strand used in comparison to the flat reed of the other photograph.

tile and wicker-work. During the war there arose an amazing lack of clothing, bags, cordage and other articles of this nature. The strength of paper, which has long been used in railway car wheels, its pliability and other abilities to be treated chemically, so that when completed it can resist weather conditions without injury, evidently turned the human mind to paper. Tests have proven that a piece of twisted paper gauging  $\frac{1}{16}$  of an inch is stronger than any known steel of the same weight. Experiments have proven that certain hard or tightly-twisted paper  $\frac{1}{16}$  of an inch in diameter will not break unless the tension is more than 50 pounds, while the same thickness of reed will not stand a strain of 13 pounds. G. L. Brownell made the first real paper-twine machinery 17 Dec. 1895. Gradually the use of twisted paper as a textile became general in the manufacture of clothing, bags, cordage, belts, caps, hats, braces and leather substitutes. Then it spread to wicker-work, where it finds its most adaptable place. Germany and Austria have made tremendous strides in the paper-fibre trade. Special machinery for making textile and wicker fibre from reels of paper are now manufactured. The Scandinavian countries are producing large amounts of paper fibres, while the British government has for some time been interested and busy in the manufacture of paper fibre articles. The even-

ness of strength, freedom from odor, absence of loose ends, flexibility, elasticity, strength, as well as weather and water-proofing qualities make paper fibre to-day the most important strand in the manufacture of wicker-woven articles. In addition to the above advantages it is much cheaper and more abundant than any other form of wicker. The ability of paper to permit itself to be manufactured into wicker fibre, either alone or with cotton, wool and even wire centres, and its ability to accept modern

chemical and other treatments for purposes of strength and elasticity, adds to its importance and growing popularity. All other forms of wicker are used in a more or less natural state and do not require or lend themselves to chemical or other advanced treatments of manhood. Wicker fibre, however, overcomes these objections. Since all other wickers except wicker fibre are used practically in their natural state it is necessary to weave the strands in large sizes. This does not make possible for them the beautiful finishes of the wicker-fibre articles. Owing to the smallness of the best hard wicker fibres, the article manufactured usually has from two to four times as many feet of fabric as the natural wicker woven articles, therefore making the wicker fibre article stronger. The shortness of natural wickers, like willow and reed, make it necessary for ends to occur frequently in furniture, baskets or baby carriage bodies. Wicker fibre can be made in endless strands, thus doing away with unsightly ends. Wicker fibre originates, like paper,

from the forest with fir and pine proving the most satisfactory wood, although almost any kind can be used. After the trees have been cut and the logs sent to the paper mills a pulp is formed. (See PAPER). This pulp becomes paper and is cut into ribbons of various widths. These reels of paper ribbon are run through baths of casein glue for purposes of preservation and toughening. Then the ribbons enter twisting devices running 5,000 revolutions per minute. Sometimes wire centres are used but usually pure paper fibre is manufactured. The twisted paper ribbon is dried on large drums and then ready for weaving. After being woven the shaped article is dried and painted from two to four times with enamel or shellac. These various treatments make the fibre absolutely impervious to water, sunshine and other weather conditions.

**Methods of Weaving.**—Hand weaving must have been the only method used in biblical days, so far as wicker weaving is concerned, for there is no mention of any machine being used. The biblical method consisted of weaving two strands at right angles to each other, considerably or exactly like textile weaving. (See TEXTILE INDUSTRY). When wicker was to be woven a frame was made and the upright strands or weft attached to it. Then the warp was interlaced through the weft. The method has been handed down through all

## WICKER WEAVING

**1 MAKING THE WEFT**— This machine is twisting specially manufactured paper about wire, shaping it and cutting off to desired lengths. The paper is the same as that used in making the warp. It is one-eighth of an inch in diameter and has a breaking point of 175 pounds. (A) Reel of paper ribbon; (B) Strand entering machine; (C) Strand in casein glue bath; (D) Twisting paper entering dies and twisting device; (E) Sizing die; (F) Partially twisted wicker fibre; (G) Feeding device; (H) Automatic guide for winding fibre on spool; (I) Spool of wicker fibre; (J) The warp.

**2 MAKING THE WARP.**— The above machine shows how paper is twisted into wicker fibre. Before coming to this machine the paper has gone through many mechanical and chemical treatments so as to make it specially adaptable for wicker usage. Following its formation the wicker still has many other processes to pass through before being ready for market in the shape of manufactured articles. The wicker fibre being made in the above is one-thirtieth of an inch in diameter and has a breaking point of 50 pounds. (A) Spool of wire; (B) Wire entering machine; (C) Straightener; (D) Rolls of paper ribbon; (E) Paper being wrapped about wire; (F) Paper being twisted tightly about wire while held by die; (G) Wicker fibre with wire centre; (H) Feed rollers shaping wicker; (I) Automatic cutter; (J) The weft.

## WICKER WEAVING

1 Lloyd Loom

2 Wicker woven chair made of wicker fibre on the Lloyd loom. Note the close and even weave

ages and through all peoples until to-day. Many men have tried to change the method of the biblical days but failed. More tried to use the same method and weave wicker on machines like textiles are woven. But all of these inventors, save one, were doomed to failure. Marshall B. Lloyd of Menominee, Mich., spanned the gap of centuries by changing the method of weaving before trying to make a machine loom which would do the weaving. Instead of attaching either the weft or warp to the frame of the article desired, he found a way of weaving the wicker independent of the frame and then attaching the wicker-work to the frame. Any of the modern wickers lend themselves to his method. Later he produced a machine known as the Lloyd Loom, which weaves the wicker 30 times faster than the most expert hand weaver can and with far greater superiority. The loom also lends itself to weaving any kind of wicker strand. The Lloyd Loom requires that the weft be attached to a drum. The warp is fed through a stationary shuttle after being made more or less continuous by connecting the ends of various pieces of wicker or by making continuous wicker fibre. The average baby-carriage body of endless wicker fibre is usually woven on the loom in 18 minutes, while a hand weaver would require an entire day of nine working hours to accomplish the same results. And even then his work would not be nearly as smooth and beautiful. This is due to mechanical exactness in weaving as compared with human lack of exactness, as is very evident when the old home-spun textiles are compared with modern machine-woven products. The weaving of cane for chair seats, etc., has been in vogue for 25 years. This kind of weaving is called flat weaving and requires no shaping as does furniture, baby carriages and baskets. Hence, the early solution of its mechanical weaving problems.

**Wicker-Woven Baby Carriages.**—The development of the baby carriage has been slow. The first "baby carriages" were merely baskets like that in which Moses was found. The American Indian mother with her papoose strapped on her back, either in skins or in woven articles, according to weather conditions, originated another form of the "baby carriage." While there is no authentic data to show the development of the baby carriage yet it is taken for granted that when man put wheels under a sledge, thus making a wagon, he conceived the idea which led to the modern wagon, baby carriage, train and even the automobile. The first form of a baby carriage was a basket with a wheel on either side. Then came the elaborate chariot-like carriage but still with only two wheels. The latter came into prominence in the 18th century. Early in the 19th century the baby carriage took the shape of the average toy express wagon with four solid wood wheels. Then came the collapsible carts which could be folded up into a small article. Wicker-woven carriages regained prominence in the 20th century, and to-day they dominate. Most of them are made of beautifully woven bodies or baskets. The finer the strand the more even the weaving, and the greater the cost to the ultimate purchaser. The bodies are set on steel springs which

are either air or oil tempered, the latter producing more resiliency and solidity. Four wheels, two on either side, made of wood or wire and with rubber tires, a woven hood or top, a storm shield, smooth and soft upholstery and wheel brakes complete the carriage.

**Wicker-Woven Baskets.**—These articles have been made ever since biblical days, as shown in the above Bible references. There has been little advancement in the art. The usual wickers described above have been and are being used.

**Wicker-Woven Furniture.**—The Bible gives very little information on what sort of furniture was used at that time. It is said that the early Egyptians wove bedsteads of wicker-work, but what the make-up of the wicker was is not known. In 1650 a few chairs were made of wicker, while in 1711 wicker and cane chairs seem to have secured considerable general usage. In the 16th century the Hollanders made heavy wooden chairs and used woven cane or rush seats. The 19th century found chairs made of wicker willow and wicker reed. Tables, davenport, desks and bedroom furniture later were made of various kinds of wicker. The high cost of weaving, great waste of material, numerous short unsightly ends, combined with the lack of wearing and weather-proofing qualities kept the quantity of wicker-woven furniture to a very low ebb when compared with the vast volume of furniture made and used in the world.

GEORGE W. ROWELL, JR.

**WICKERSHAM, George Woodward**, American cabinet officer and lawyer: b. Pittsburgh, Pa., 19 Sept. 1858. He studied at Lehigh University and took his degree in law at the University of Pennsylvania in 1881. He first engaged in practice in Philadelphia, but after 1882 he practised in New York. He was for many years a member of the law firm of Strong and Cadwalader; was counsel for the companies reorganizing the Chicago traction lines; for the Interborough Rapid Transit Company in the construction of the New York subway; and for the builders of the Pennsylvania tunnels in New York. He was connected with the reorganization of the Mexican railway system; and had a wide experience in railway litigation in the United States. He was appointed Attorney-General of the United States by President Taft in 1909, and served in that capacity throughout the Taft administration. He was especially successful in his handling of the government's anti-trust litigation, and his management of the cases against the Standard Oil Company and the Tobacco Trust was particularly brilliant. He was afterward a member of the law firm of Cadwalader, Wickersham and Taft.

**WICKET** (Wall. *wicket*; Norman, *viquet*; French *guichet*, a little door within a gate; all from Iceland *vikja*, to give way), a small gate or door; part of a massive or large door for the admission of persons on foot only; the three stumps or rods stuck in the ground and supporting the bails, against which the ball is directed in the game of cricket.

**WICKING**, in curling, an ingenious master-stroke by which a stone is sent in an oblique

direction so as to hit the winner's stone and drive it from the tee, the former often replacing the latter and so becoming the winner in turn; also called "inringing."

**WICKLOW**, wĭk'lō, Ireland, a maritime county of Leinster Province, on the Irish Sea, with an area of 782 square miles. Chief town, Wicklow. The county generally is mountainous, but has fertile lowlands where oats and potatoes are cultivated, and much pasture land devoted to stock-raising. Iron and lead are mined, and a little copper. Pop. about 60,000.

**WICLIF**, wĭk'lĭf, **WICLIFFE**, **WICLEF**, **WICKLIFF**, or **WYCLIFF**, John, English reformer: b. Spreswell, Yorkshire, probably about 1330; d. Lutterworth, 31 Dec. 1384. He studied at Balliol College, Oxford, of which he became master between 1356 and 1361, in which later year he was appointed by his college to the living of Fillingham, in Lincolnshire. About the same time the Pope bestowed upon him a prebend in the collegiate church of Westbury-on-Trym, near Bristol, in which he was confirmed by the king. In 1368 he gave up Fillingham and accepted the living of Ludgershall, in Buckinghamshire, and four years later qualified as doctor of theology. He was presented by the Crown in 1374 to the benefice of Lutterworth, in the south of Leicestershire, which he held till his death. A Latin tract 'Determinatio quædam Magistri Johannis Wycliff de Dominio contra unum Monachum,' has been regarded as belonging to the controversy raised by the refusal of the Parliament of 1366 to pay a tribute demanded by the Pope Urban V, in virtue of the homage paid by King John to Innocent III, but some authorities refer it to a date about 10 years later, when similar circumstances arose. At the time of writing the tract, Wiclif was regarded as royal chaplain, for he calls himself *peculiaris regis clericus*, and in 1374 was named second on a commission which went to Bruges to try to settle disputes concerning ecclesiastical jurisdiction with the representatives of the Pope Gregory XI. He had shortly before been appointed a canon of Lincoln, but never actually obtained a prebend in that cathedral. The development of his views on the relation between the ecclesiastical hierarchy and the secular authorities brought him into close association with John of Gaunt, duke of Lancaster, and his party, and in 1377 the anti-Lancastrians sought to strike at their political opponents through Wiclif. He was summoned in that year before Archbishop Sudbury and his suffragans at Saint Paul's, and attended, accompanied by Lancaster, Lord Percy, and other powerful Lancastrians. A violent altercation between the duke and William Courtenay, bishop of London, caused the break-up of the meeting, and the infuriated populace plundered Gaunt's palace and attacked Percy's house. Soon afterward Pope Gregory sent several bulls to the University of Oxford, the archbishop of Canterbury, and the bishop of London, in which he accused Wiclif of teaching the condemned doctrines of Marsilius of Padua and John of Jandun, and ordered him to be arrested and examined. The parties were reluctant to move in view of Wiclif's great popularity and influence, and even after the

bulls had arrived he was consulted by the government as to whether they might legally prevent money from going abroad to absentee holders of benefices. He eventually appeared before the prelates at Lambeth in 1378, but the king's mother sent a message forbidding them to interfere with him, and a popular demonstration in his favor put an end to the proceedings. In the Gloucester Parliament of 1378 he made a defense of John of Gaunt, who had grossly violated the Westminster right of sanctuary.

This year, 1378, was an important date in Wiclif's religious career. While continuing to inveigh against certain abuses, he began to question the whole basis of sacerdotalism and its authority, and by 1381 had attained to a substantially Lutheran position in regard to transubstantiation and the mass. About this time also he commenced his appeal to the common people and presented religion as a popular force rather than a dogmatic system or an organized institution. This appeal assumed two forms: the sending out of his "poor preachers" and the translation of the Bible from the Vulgate into the English of his day. His itinerant evangelists spread his doctrines throughout the land and soon made the Lollard movement one of great strength and importance. In his translation of the Bible he had the assistance of Nicholas Hereford, who was responsible for most of the Old Testament, and the whole work was revised by his assistant, John Purvey, who finished it soon after Wiclif's death. Wiclif's views on the eucharist were promptly condemned at Oxford and forbidden to be taught there, and in 1382 Courtenay, archbishop of Canterbury, summoned a council in the Blackfriars' convent hall, at which Wiclif's teaching was condemned and some of his followers excommunicated. This council known as the "earthquake council" because a violent earthquake occurred during the meeting, ordered the Carmelite, Dr. Stokes, to publish the condemnation at Oxford. The chancellor of Oxford University at that time, Robert Rygge, was a supporter of Wiclif and evaded the duty of carrying out the council's mandate until absolutely compelled to do so. Wiclif himself remained untouched, but he retired to Lutterworth, where he occupied himself in preaching and writing. It is said that Urban VI summoned him to Rome in 1384, but this is doubtful. He had a paralytic stroke in 1382 or 1383, and again in 1384, from which he died. He was buried at Lutterworth, but in 1428, in accordance with a decree of the council of Constance in 1415, his body was exhumed and burned, and his ashes thrown into the river Swift.

Of the 24 Wiclifite propositions condemned by the earthquake council, 10 were described as heretical and 14 as erroneous. The most important of the 10 were: that transubstantiation is philosophically false, since the substance cannot be changed while the accidents remain; that transubstantiation is not taught in the Gospels; that confession is not necessary to salvation; that no one after Urban VI should be recognized as Pope; and that it is unscriptural for ecclesiastics to hold temporal possessions. Of the erroneous doctrines, several seriously limited the right of excommunication in a distinctly

Protestant sense, one asserted the right of unlicensed preaching, another declared that dominion, whether civil or ecclesiastical, could not belong to one in mortal sin, and another distinctly asserted the authority of the temporal power over the ecclesiastical in temporal affairs. Wiclif unmistakably made his appeal to Scripture as of higher authority than Church tradition or decrees, and had a strong sense of the individualistic basis of religion. He never reached the Lutheran doctrine of justification by faith, but from denunciation of abuses in the Church rapidly advanced to his three main positions: that all dominion was of divine origin and was forfeited by anyone in mortal sin; that transubstantiation was a doctrine both unphilosophical and unscriptural; and that monasticism in every form was a corrupt institution.

At first he attacked only the luxurious and corrupt orders of monks and was on friendly terms with the friars, but from about 1379 the friars were also included in his condemnation. He was one of the last of the realists in philosophy, and he tried to reconcile predestination with the freedom of the human will. Not only was Wiclif one of the chief forerunners of the Reformation, but he was also a pioneer in English prose literature. He wrote many learned works in Latin, but the nature of his message and the necessities of his position led him to appeal to the people in works in their own tongue. His chief Latin works are 'De Dominio Divino'; 'De Dominio Civili'; 'De Officio Pastoralis,' and 'Trialogus.' All, except the 'Trialogus' and the 'De Officio Pastoralis,' and also volumes of Latin sermons and a volume of Polemical Works, have been edited by English and foreign scholars for the Wiclif Society. The excepted words were edited by Lechler (1869 and 1863 respectively). His translation of the Bible was edited by Forshall and Madden (1850); and his English works are to be found in the three collections 'Three Treatises of John Wycliffe' (1851), by Todd; 'Select English Works of Wyclif' (1869-71), by T. Arnold; and 'The English Works of Wyclif' hitherto unprinted (1880, Early English Text Society), by F. D. Matthew.

**Bibliography.**—'Wiclif' in the Dictionary of National Biography; Lechler, 'Johann von Wiclif und die Vorgeschichte der Reformation' (1873); Poole, 'Wycliffe and Movements for Reform' (1889), and 'History of Mediaeval Thought' (1884); Burrows, 'Wyclif's Place in History' (1881); Buddensieg, 'Johann Wiclif und seine Zeit' (1885); Stevenson, Jos., 'The Truth About John Wyclif'; Parson, 'Studies in Church History' (Vol. 2); Gasquet, F. A., 'The Eve of the Reformation'; and Cadman's article on Wycliffe in 'Three Religious Leaders of Oxford' (New York 1916).

**WIDDIN**, vid'in, or **VIDIN**, Bulgaria, a town on the right bank of the Danube, near the Serbian frontier, consisting of three parts, the town on the Danube, the walled city and the citadel. The principal buildings are the palace, several mosques with lofty minarets and a range of bazaars lining the main street. Ships can reach the town at high-water. There is a considerable trade, chiefly in corn, wine and salt, and the chief manufactures are gold and silver filigree work and jewelry. Widdin

was formerly strongly fortified and during Russo-Turkish wars was important strategically, but the Treaty of Berlin (1878), which erected Bulgaria into a hereditary principality tributary to the Porte, decreed that its fortifications should be dismantled. Pop. about 15,000.

**WIDE AWAKES**, in American political history, a name adopted by numerous Republican campaign clubs organized for the purpose of aiding in the election of Abraham Lincoln during the Presidential campaign of 1860. The first club was organized in Hartford, Conn. It is stated that in New York City there were on one occasion 20,000 Wide Awakes marching in procession.

**WIDE, WIDE WORLD**, *The*, a tale by Susan Warner, published in 1851 under the pen name of "Elizabeth Wetherell." It reached a sale of over 300,000 copies. The life of the heroine, Ellen Montgomery, is followed from early childhood to her marriage with a fullness of particulars which leaves nothing to the reader's imagination. The scenes and episodes are those of a homely, every-day existence, described with close fidelity to detail. Ellen's spiritual experience is minutely unfolded, and the book was long regarded as one of those which are "good for the young." The criticism of a later generation pronounces it mawkish in sentiment and unreal in conduct. It stands among the fading fancies of an earlier and less exacting literary taste.

**WIDENER**, Peter A. Brown, American capitalist: b. Philadelphia, Pa., 13 Nov. 1834; d. 6 Nov. 1915. He acquired a large fortune in the meat business, entered politics, was appointed city treasurer of Philadelphia in 1873 and in 1874 was re-elected to that office. He became largely interested in street railway corporations, and was associated with both the tobacco and Standard oil groups of capitalists. In 1897 he presented to the city of Philadelphia his private residence, valued at \$600,000, for a branch of the Free Lending Library, and in the following year gave to the library a collection of 500 rare books valued at \$28,000. In 1899 he endowed at Philadelphia the Widener Memorial Training School for Crippled Children, a combined home, hospital and school. The school site consists of a tract of 36 acres at Logan, a Philadelphia suburb.

**WIDGEON**, or **WIGEON**, a river-duck of the genus *Mareca*. Widgeons have a short bill, rounded at the tip, with a strong, broad nail, and the upper lamellæ prominent; wings long and pointed; tail, moderate and wedge-shaped. There are about 10 species in various parts of the world. They are found on the seashore and on the margins of lakes and rivers, feeding chiefly on vegetable substances, and performing periodical migrations at night in vast flocks. The American widgeon or baldpate (*M. americana*) is about 18 inches long; the bill is blue, black at the base and tip; upper parts finely waved transversely with dark lines; lower parts mostly white; top of head nearly white, with a broad green patch around and behind the eyes; the rest of the head and neck grayish, spotted and banded with black; the wing-covers are white, the greater part tipped

with black; the speculum is green, encircled by black. The baldpate is found throughout North America, breeding chiefly north of the United States and wintering in Central America. It is an active bird, with a swift and well sustained flight, in ranks of various and irregular forms, and it associates during the winter with teal and other ducks. The flesh is highly esteemed, especially when they have fed in the rice fields of the South, or along with the canvas-back on the water-celery of the Chesapeake. They do not dive, but feed with the head and neck immersed, swimming very near together. Their food consists of aquatic seeds, roots, insects, worms, small fry, leeches, nuts and grain, especially rice in the rainy season; being very fond of the tender aquatic plants on which the canvas-back feeds, and no diver itself, it watches the latter and snatches the morsels as it emerges and before it has had time to open its eyes. They are among the most difficult ducks to shoot, owing to their shyness and swift, irregular flight. The nest is built on the ground, often far from water and usually of leaves lined with down. The eggs number eight or 10, are pure ivory white and about two inches long by nearly one and one-half in diameter. The European widgeon (*M. penelope*) is rather smaller, and not uncommon all along the Atlantic Coast of the United States, as well as on the Pacific. It differs chiefly in having the head and neck reddish brown or cinnamon, the top of the head cream-colored. Consult Grinnell, 'American Duck Shooting' (New York 1902).

**WIDNES**, England, a manufacturing town in Lancashire, on the Mersey, opposite Runcorn, 13 miles east-southeast of Liverpool. There are extensive chemical, alkali and soda works; soap, candle, grease and manure works; copper-smelting works and rolling-mills, and iron-foundries. The town has a considerable carrying trade, which has been further developed by the construction of large docks in 1866, extended in 1884. Pop. 30,000.

**WIDNMANN**, vid'n-män, **Max**, German sculptor: b. Eichstätt, Bavaria, 13 Oct. 1812; d. Munich, Bavaria, 3 March 1895. He was educated at Munich and at Rome, executing while at the latter city his "Shield of Hercules," considered one of his masterpieces, and in 1849 became professor of sculpture at the Academy of Art at Munich. Several of the public monuments in that city are by him, but his best work is considered to be shown in his busts and statuettes, which, however, are fewer in number. His statues include those of Orlando de Lasso (1848); Schiller (1863); Goethe (1868); Castor and Pollux (1877). Specimens of his workmanship are to be found at Bamberg, Ratisbon, Würzburg and other cities.

**WIDOW**, one who has lost her husband by death and remains unmarried. A "grass-widow" is a divorced woman. Among the ancients was practised a form of funeral sacrifice, in which the widow was slain or induced to commit suicide so that she might be buried with her husband and accompany him to the world of spirits. This practice is mentioned as existing among the Greeks by Euripides and Pausanias, and from Caesar it may be inferred that it existed also in Gaul. Widow sacrifice is still the

custom in some African tribes; traces of it may be found in China; it lingered till late in the first half of the 19th century in Fiji, and though abolished by law in British India in 1829, was not wholly stamped out until late in the 19th century.

**WIDOW BEDOTT** (bē-dōt') **PAPERS**, **The**, a collection of broadly humorous sketches by Frances Miriam Whitcher, which appeared first in Neal's *Saturday Gazette* of Philadelphia, about 1847, and in book form in 1855. They were extremely popular in their day and are still read and quoted from, though they have been followed by many works in a similar vein.

**WIDOW-BIRD**. See **WHYDAH-BIRD**.

**WIELAND**, vē'lant, **Christoph Martin**, German author: b. in the Swabian village of Oberholzheim, near Biberach, 5 Sept. 1733; d. Weimar, 20 Jan. 1813. The son of a country clergyman, after thorough preparation, he went in 1750 to the University of Tübingen to study law, but most of his time was devoted to *belles-lettres*. In 1751 appeared his 'Zwölf Moralische Briefe,' which met with very favorable reception. He also wrote at this time the didactic poem, 'Anti Ovid.' In 1752 he went to Zurich as a literary companion to J. J. Bodmer (q.v.). Inspired by the deeds of Frederick the Great to write a poem exhibiting the ideal of a hero, he chose the story of Cyrus. The first five cantos appeared in 1759, but the poem remained unfinished. About this time he published 'Araspe and Panthea,' an episode from the 'Cyropædia' of Xenophon. After a brief residence he left Bodmer's house, became a tutor, and in 1760 returned to Biberach. In 1762 he went to live with Count Stadion, an accomplished scholar, but a thorough man of the world, averse to all religious enthusiasm. Wieland had been prone to religious mysticism; but the gay pleasure-seeking life of the society with which he now came in contact, and the sceptical and cynical kind of literature now most at his command, produced an entire change of sentiment. The first indication of this new philosophy of life appears in the tale of 'Nadine,' which he styles a composition in Prior's manner. This was followed in 1764 by 'Die Abenteuer des Don Sylvio de Rosalva' ('The Adventures of Don Sylvio de Rosalva'), a work for which Don Quixote serves as model. In 1766-67 appeared his 'Agathon,' which established his reputation. The 'Musarion' (1768), a production distinguished for grace, ease and harmony, advocates a rational unity of the sensual and spiritual. In 1770 he wrote 'Die Grazien' ('The Graces'); and the 'New Amadis' in 1771, a poem which celebrates the triumph of intellectual over mere physical beauty. In 1769 he was appointed *professor primarius* of philosophy at the University of Erfurt. In his 'Verklagter Amor' ('Cupid Accused') he defended amatory poetry; and in the 'Dialogen des Diogenes von Sinope' (1770) gave a general vindication of his philosophical views. In 1772 he was invited to Weimar by the Duchess Anna Amalia as tutor to her two sons. Turning his attention to dramatic poetry, he wrote the 'Wahl des Hercules' ('Choice of Hercules'), and the 'Al-

ceste.' He also edited the 'Deutscher Mercur,' a monthly, which he conducted till near the close of his life. His views, as exhibited therein, however, showed so much of the narrow conventional spirit of French criticism, that he was attacked by Goethe in the satire 'Götter, Helden und Wieland' ('Gods, Heroes and Wieland'). This Wieland answered with great good nature, recommending it to all who were fond of wit and sarcasm. Goethe and Herder were soon drawn to Weimar, where the Duchess Anna Amalia formed a circle of talent and genius, later also joined by Schiller. In 1774 appeared the 'Geschichte der Abderiten,' in which Wieland sought with an engaging wit to correct the provincialism of his time. 'Oberon' (1780), a romantic epic, is the most finished of his works. Wieland also prepared translations of Horace, Lucian and the 'Letters' of Cicero. His translations of Shakespeare (1762-66), made the English poet "an open book for Germans." He superintended (1794-1802) an edition of his 'Works' in 45 volumes. These were also edited by Gruber (1818-28 and 1867-75), and there are many editions of selections, some of which have been translated into English. Wieland's place in literature in a sense falls within the group headed by Goethe, Schiller and Lessing; not so stellar as these, he was yet singularly attuned to his time. A veritable German Voltaire, his influence, exerted especially through the 'Deutscher Mercur,' was immense. Of facile and incessant wit, no other writer had more to do with shaping the German language to elegant expression. This explains the delight with which the work of Wieland was met in his day. Consult Loebell, 'Entwicklung der Deutschen Poesie' (1858); Ranke, 'Zur Beurtheilung Wielands' (1885); Hirzel, 'Wieland's Beziehungen zu den Deutschen Romantikern'; Lenz, W., 'Wieland's Verhältniss zu Spenser, Pope, and Swift'; and Gruber's biography, with his editions.

**WIENER**, vē'nēr, Leo, Jewish-American author: b. Russia, 26 July 1862. He was educated at the gymnasium of Minsk and Warsaw, at the University of Warsaw and the Polytechnic of Berlin. From the latter city he went to New Orleans, worked in a cotton factory, and later sold fruit in Kansas City, Mo. He then obtained a position as teacher in Odessa, Mo., and afterward a professorship in the University of Missouri, and was next appointed to his present position as assistant professor of Slavonic languages at Harvard. He contributed many etymologies to Webster's New International Dictionary, but his greatest editorial production is the 24-volume compilation of Count Tolstoy's works. Among his other publications are 'History of Yiddish Literature in the 19th Century'; 'Anthology of Russian Literature'; 'Slavic Anthology'; and 'An Interpretation of the Russian People' (1915); he has also edited Rosenfeld's 'Songs from the Ghetto.'

**WIENER-NEUSTADT**, vē'nēr-noi'stāt, Austria. See NEUSTADT.

**WIERTZ**, vērts, Anton Joseph, Belgian painter: b. Dinant, 22 Feb. 1806; d. Brussels, 18 June 1865. He studied art in the Antwerp

Academy, where he gained, in 1832, a prize which enabled him to continue his studies in Rome. On his return to Belgium he lived at Liège for a time, and from 1848 at Brussels, where the Belgian government erected a large studio for him in 1850. Wiertz was a painter of great, though eccentric, genius, with a strange predilection for horrible and fantastic subjects, and invented a method of painting, called by himself *peinture mate*, in which the characteristics of fresco and oil painting are combined. His principal pictures are 'Greeks and Trojans contending for the Body of Patroclus'; 'The Flight into Egypt'; 'Death of Dionysius'; 'The Triumph of Christ' (1848), his masterpiece; 'The Things of To-day in the Eyes of the Men of the Future'; 'The Beacon of Golgotha'; 'The Last Cannon'; 'Napoleon in Hell'; 'A Second after Death.' He did not sell any of his chief paintings, which he bequeathed to the state, but supported himself by painting portraits. His Brussels studio, fitted up after his death as the Musée Wiertz, contains his large pictures. He wrote 'Eloge de Rubens' (1840); and 'Caractères Constitutifs de la Peinture Flamande' (1863). Consult Labarre, 'Auroine Wiertz' (1866).

**WIESBADEN**, vēs'bā-dēn, Prussia. (1) A town in the province of Hesse-Nassau, capital of the government of Wiesbaden, and formerly capital of the Duchy of Nassau, beautifully situated among vineyards and orchards on the southern slopes of the Taunus range, about three miles north of the Rhone and 20 miles west of Frankfort. For many years it attracted about 80,000 visitors from all parts of Europe by its baths. Among notable buildings are the royal palace, the ducal palace, the town-house, the government buildings, the courthouse, the museum and picture-gallery, the library (100,000 vols.), the royal court theatre, the Trinkhalle, and the Kurhaus, consisting chiefly of a large and splendid saloon, forming the east side of a square, while the north and south sides are lined by colonnades, filled with gay shops, and uniting a promenade and a bazaar. The springs, all of which except one are alkaline and among the most powerful of their class, are very numerous, and have temperatures varying from 100° to 153° F. The springs of Wiesbaden are spoken of by Pliny as the "Fontes Mattiaci," and on the Heidenberg, north of the town, traces of a Roman fortress were discovered in 1838, which seems to have been connected with the town by a wall, the Heidenmauer ("heathen's wall"), in the ruins of which votive tablets and inscriptions have been discovered. Pop. 90,000. (2) The government of Wiesbaden comprises almost the whole of the former Duchy of Nassau, most of the territory which belonged to the city of Frankfort, etc. Area, 2,108 square miles; pop. about 1,200,000.

**WIFE**. See HUSBAND AND WIFE.

**WIG**, an artificial hair covering for the head to conceal baldness, or to alter the appearance. They are usually made of human hair woven into a cap that fits the head tightly. Those worn for baldness are politely termed toupees. The use of wigs is traced back to the ancients. They were used especially by the women. The fashion is said to have been copied by the Greek

ladies from those of Egypt. Under the Roman emperors it became common even for men to wear wigs, and several of the emperors themselves used this ornament. In the latter half of the 16th century the fashion became much in vogue in France, Italy and England. In 1560 no lady appeared at the French court without a blonde wig. Louis XIII set the fashion, wearing a wig of long curls, being himself bald. The courtiers naturally followed. Louis XIV was at first averse to wigs; but in the latter part of his reign, when he began to lose his own hair, he reintroduced the fashion, which went to a greater extreme than ever. About 1660 they began to be worn by the clergy, who had at first shown themselves hostile to the practice. The practice of powdering these wigs was adopted about the year 1700. About 1720 the great wig began to give place to the queue, which remained the fashion till early in the 19th century. Modern refinement has abolished the wig as an ornament except in Great Britain for the lord-chancellor, judges and barristers. They are still worn by actors and actresses as a part of the make-up or dress suitable to a particular character.

**WIGAN**, England, a town of Lancashire, on the Douglas, 21 miles northeast of Liverpool. Wigan stands in the centre of an extensive coal field, and its manufactures, which are important, consist chiefly of calicoes, fustians and other cotton goods, linens, checks, cotton twist, etc., besides iron foundries, iron forges, railway car works, iron rolling mills, large breweries, chemical works and corn and paper mills. It has a Mining and Technical College. Pop. 90,000.

**WIGGIN**, wig'in, Kate Douglas Smith, American author: b. Philadelphia, Pa., 28 Sept. 1859. She was educated at Abbott Academy, Andover, Mass., and in 1876 went to California, where she studied the kindergarten system in Los Angeles, and later at San Francisco organized the first free kindergarten in the West. In 1880 she was married to S. B. Wiggin, a lawyer (d. 1889), and removed to New York. In 1895 Mrs. Wiggin was married to George C. Riggs. In 1906 Bowdoin College gave her the Litt.D. degree. She published, with her sister, Nora A. Smith, 'Froebel's Gifts' (1895); 'Kindergarten Principles and Practice' (1896), etc. Her other works, several of which have attained great favor in this country and England, include 'The Bird's Christmas Carol' (1888); 'The Story of Patsy' (1889); 'A Cathedral Courtship' (1893); 'Mann Lisa' (1896); 'Penelope's Progress' (1898); 'Penelope's Experience in Ireland' (1901); 'Diary of a Goose-girl' (1902); 'Rebecca of Sunnybrook Farm' (1903); 'New Chronicles of Rebecca' (1907); 'Susanna and Sue' (1909); 'Mother Carey's Chickens' (1911; dramatized 1915), etc.

**WIGGINS**, Benjamin Lawton, educator: b. Sand Ridge, S. C., 11 Sept. 1861; d. Sewanee, Tenn., 1909. His education was received at the University of the South from which he was graduated in 1880. He afterward (1883-84) pursued graduate work at Johns Hopkins University. In 1882 he returned to the University of the South as professor of Greek, which position he held until his death, with the added

duties (after 1893) of vice-chancellor or president. Under his supervision the University of the South became one of the leading institutions in the Southern States.

**WIGGINS**, (John) Carleton, American artist: b. Turners, N. Y., 4 March 1848. He studied at the National Academy of Design in New York and under George Inness and H. Carmiencke and later in Paris. He first exhibited at the National Academy in 1870, and at the Paris Salon in 1881. He painted landscapes, and was especially successful in his paintings of cows. He was elected to the National Academy in 1906. His works are well represented in both public and private collections. Among them are 'A Holstein Bull' (Metropolitan Museum of Art, New York); 'Morning on the Hills' (Brooklyn Museum); 'October' (Corcoran Art Gallery, Washington); 'Lake and Mountains' (Chicago Art Institute); 'Evening after a Shower' (National Gallery, Washington); 'The Wanderers' (Hamilton Club, Brooklyn); 'Ploughing in France'; 'Plough Horse' (Lotus Club, New York); 'After Wind—Rain,' etc.

**WIGGINS**, Guy Carleton, American artist, son of (J.) C. Wiggins (q.v.): b. Brooklyn, N. Y., 23 Feb. 1883. He studied under his father and at the Polytechnic Institute, Brooklyn, and the National Academy of Design, New York. He is notably successful in his portrayal of scenes in New York, and is also known for his landscapes. Among his works are 'Metropolitan Tower' (Metropolitan Museum, New York); 'Columbus Circle, Winter' (National Gallery, Washington); 'Berkshire Hills, June' (Brooklyn Museum), etc. He was made associate of the National Academy in 1916.

**WIGGINS**, Joseph, English sea captain and explorer: b. Norwich, 3 Sept. 1832; d. Harrogate, 13 Sept. 1905. He was apprenticed to his uncle, a shipowner, at the age of 14 and at 21 rose to be master of a ship. He afterward became owner of several cargo vessels and developed a keen interest in the project of developing a trade route between the countries of northern Europe and Siberia by means of the Northeast Passage through the Arctic seas. His first voyages, in 1874, 1875, 1876 and 1886-87 were less successful for the actual cargo delivery than for their awakening of interest in the matter and for his brilliant achievements as a navigator, demonstrating the possibility of taking ships far beyond any point hitherto reached. In 1887 he sailed up the Yenisei River to Yeniseisk. His first notable achievement in the delivery of a cargo was that of a shipment of rails for the Trans-Siberian Railway, in 1893, for which feat he was honored by the tsar. He made another successful visit to Yeniseisk in 1895. He was selected to take charge of a relief expedition into Siberia at the time of the famine in 1905 but died while preparations were under way. He received in 1894 the Murchison Medal of the Royal Geographical Society. Consult Johnson, H., 'Life and Voyages of Joseph Wiggins' (London 1907).

**WIGGLESWORTH**, wig'lx-wérth, Michael, American Puritan clergyman: b. Yorkshire, England, 1631; d. Malden, Mass., 10 Jan.

1705. In 1638 he was brought to Charlestown, Mass., by his father and accompanied him in the same year to New Haven, Conn. He was graduated from Harvard in 1651, subsequently becoming a tutor there. He then studied theology and was settled as pastor of the Church of Malden in 1656. He was accounted skilful in medicine, and was offered the presidency of Harvard in 1684, but on account of ill health declined the honor. His best-known work, 'The Day of Doom' (1662), was a popular poem in New England for a long period. Two editions were printed in England and the sixth edition in New England appeared in 1715. The savage Calvinism of the poem is unsurpassed in literature save perhaps in Jonathan Edwards' sermon, 'Sinners in the Hands of an Angry God,' but the work contains not a little dramatic force and here and there passages of dignity and beauty. He also wrote 'God's Controversy with New England' and 'Meat out of the Eater,' in verse; and 'A Discourse on Eternity.' Consult Tyler's 'History of American Literature' (1878); and Dean, 'Memoir of Michael Wigglesworth' (1863; new ed., 1871).

**WIGHT**, wit, **Orlando Williams**, American physician and translator: b. Centreville, N. Y., 19 Feb. 1824; d. Detroit, Mich., 19 Oct. 1888. He was educated at the Rochester Collegiate Institute, removed to New York in 1847, studied theology and was ordained to the Universalist ministry. He subsequently studied medicine, being graduated from the Long Island College Hospital in 1865. He engaged as a medical practitioner in Wisconsin, and was appointed State geologist and surgeon-general in 1874. He was health commissioner of Milwaukee in 1878-80, and health officer of Detroit in 1882-88. He was a noted translator and throughout his life devoted a large share of his time to literary work. He wrote 'Maxims of Public Health' (1884); 'Peoples and Countries Visited' (1888), etc. His translations include 'History of Modern Philosophy,' with F. W. Ricord (1852); 'Lives and Letters of Abélard and Héloïse' (new ed., 1861); Martin's 'History of France,' with Mary L. Booth (1863), etc. He also edited 'Standard French Classics' (14 vols., 1858-60); 'The Household Library' (18 vols., 1859, et seq.), etc.

**WIGHT**, **Peter Bonnett**, American architect: b. New York, 1 Aug. 1838. He was graduated from the College of the City of New York in 1855, practised as an architect in New York in 1861-71, and since 1871 in Chicago. He has been secretary of the Illinois State board of architects since 1897, was elected to the American Institute of Architects in 1866, and from 1900 to 1905 was secretary of the Municipal Art League of Chicago.

**WIGHT**, Isle of, England, off the south coast, in the county and opposite to the mainland portion of Hants, is separated from the mainland by the roadstead or channel of Spithead on the east, and by the Solent or continuation of this on the west. It is about 23 miles in length from east to west, by 15 miles broad; circuit about 70 miles; area, 146 square miles. The land is rolling, affording agreeable scenery; the air is remarkably healthful. Only a small portion of the surface is waste. The downs, which cross the island from east to west and

form excellent sheep-walks, separate it into two districts, which in their general character contrast with each other, the soil on the north side being generally a stiff, cold clay, and on the south side a fertile sandy loam. On the promontory that forms the western extremity of the island are three notable chalk cliffs locally called the "Needles." Celtic tumuli occur on a number of the chalk downs, and there are monoliths of geologic interest. Excellent cement is manufactured at the works on the west side of the Medina, and largely exported. The chief imports are cattle, coal, timber and building material. The island is well defended, being protected on the east side by Sandown Fort, Bembridge Fort and Battery, and by other forts which lie between the island and the mainland. The western approach is guarded by Hurst Castle and other forts. The chief towns are Newport (the capital), Ryde, Cowes, Ventnor, Brading, Yarmouth and the fashionable health resorts of Sandown and Shanklin on the south-east coast. Osborne, near Cowes, was a residence of Queen Victoria, and with its beautiful grounds is now a national memorial, the gift of Edward VII. Its most recent use is as a college for naval cadets. Among the antiquities of the Isle of Wight the most interesting is Carisbrooke Castle, which stands a little southwest of Newport, and consists of extensive and well-preserved picturesque ruins. It has many historical associations: it is supposed to have originally been a fortress of the Britons, was afterward repaired and enlarged by the Romans, was considerably strengthened under Cerdic, who founded the kingdom of Wessex, and rebuilt in the reign of Henry I. During the Parliamentary War it became the asylum of King Charles I on his escape from Hampton Court, and afterward his prison. Another interesting remain is Quarr Abbey, about two and one-half miles from Ryde, which was built in 1132, and is now a farmhouse. Pop. 90,000. Consult Thomas's 'Isle of Wight' (Boston 1912).

**WIGMORE**, **John Henry**, American lawyer and university dean: b. San Francisco, 4 March 1863. He studied law at Harvard and practised at Boston from 1887-89. For three years following, he was professor of Anglo-American law at Keio University, Tokyo, Japan. He has since been connected with Northwestern University, first in the capacity of professor of law, and subsequently, since 1901, as dean of the faculty of law. His published works include 'Digest of the Decisions of the Massachusetts Railroad Commission' (1888); 'The Australian Ballot System' (1889); 'Notes on Land Tenure and Local Institutions in Old Japan' (1890); 'Materials for the Study of Private Law in Old Japan' (1892); 'Treatise on Evidence' (4 vols., 1904-05); 'Pocket Code of Evidence' (1909); 'Principles of Judicial Proof' (1913). He is also editor of 'Greenleaf on Evidence' (16th ed. 1899); 'Compiled Examinations in Law' (1900); 'Cases on Torts' (2 vols. 1911); 'Cases on Evidence' (1913), and co-editor of 'Select Essays in Anglo-American Legal History' (1907); 'Evolution of Law Series' (1915). Mr. Wigmore was president of the American Institute of Criminal Law and Criminology' (1909-10), and in 1916 received the

commission of major on the staff of the Judge-Advocate-General of the United States, being promoted commanding lieutenant-colonel in 1918. In February 1917 he was appointed a member of the United States High Commission.

**WIGTOWN**, or **WIGTON**, county forming the southwest corner of Scotland; bounded west by the North Channel, north by Ayrshire, east by the Stewartry of Kirkcudbright and the Solway Firth, and south by the Irish Sea. The extent from east to west is about 33 miles, from north to south about 26 miles; area, 485½ square miles, of which about 46 per cent is arable. This county which constitutes West Galloway was formed about 1341. It lies between lat. 54° 38' and 55° 4' N., and long. 4° 16' and 5° 6' W. Wigtown is somewhat irregular in form, being deeply intersected by two arms of the sea, one of which, Loch Ryan, a long narrow inlet, stretches south from the northwest corner for nine miles into the county, while Luce Bay on the south makes a wide indentation 18 miles long with an average width of 12 miles, the heads of the inlet and bay being only six miles apart. The western part of Wigtown, known as the "Rhins of Galloway," thus forms a peninsula whose length north to south is 28 miles, and breadth one and one-half to six miles; its northern extremity is Corsewall Point, and its southern the Mull of Galloway, each promontory being provided with a lighthouse. The southeastern half of Wigtown is separated from the Stewartry of Kirkcudbright by Wigtown Bay, 15 miles long and 14 wide at its mouth, and between this bay and Luce Bay Wigtown extends south in a blunt triangular form, terminating in Burrow Head. Wigtown is irregular in surface, but with no eminences exceeding 500 feet. The soil is varied, and except a portion along the sea-shore, especially in the southeastern part which consists of a rich loam — the quality is inferior. The climate is mild but moist, the rainfall being comparatively great. There are many dairy establishments. Wigtown contains three rivers of considerable size, the Cree, the Bladnoch and the Luce — the Cree and Bladnoch being navigable for a few miles. Small fresh-water lochs are numerous. There were at an early period many religious houses in the country and the church, believed to be the oldest in Scotland, founded by Saint Ninian, was built near the site the present village of Whithorn. The principal towns are Wigtown, Newton-Stewart, Stranraer and Whithorn. There is no mineral wealth and little trade or manufacture. Pop. 32,685.

**WIGWAGGING**, a system of visual signaling by means of hand flags and for short distances only. The color of the flags depends on the background. The flags used in the United States army are 18 inches square with a nine-inch centre, while those of the navy are from 12 to 15 inches square. The staffs are light and average about 24 inches in length. See **SIGNALS** and **SIGNALING**.

**WIGWAM**, among the American Indians a lodge, cabin, hut or tent, generally of a conical shape, formed of bark or mats laid over stakes planted in the ground, and converging toward the top, where there is an opening for the escape of the smoke. The most common form is the teepee, which is portable, being usually a frame-

work of roughly trimmed poles, lashed together with split wood, thongs, etc., and covered with hides, bark, matting, etc. Those designed to be more permanent, approached the log-house or bark shack in construction, and often surrounded an earth or rock fireplace, whose smoke was carried off through a central hole at the top. The word has also been applied to a large temporary structure for public gatherings.

**WILARS DE HONECOURT**, *vê-lâr dé hôn-koor*, French architect of the 13th century. He is one of the earliest recorded experimenters with the perpetual motion theory, his rude drawings of his plans being still preserved in his sketch book at the Ecole des Chartes at Paris.

**WILBER**, *wil'ber*, Neb., village, county-seat of Saline County, on the Big Blue River and on Chicago, Burlington and Quincy Railroad, 30 miles southwest of Lincoln. It is in a rich agricultural region, in which the chief products are wheat and corn. It has flour mills, grain elevators, machine shop, creameries and cigar factories. There are six churches, a high school, two newspapers and a county courthouse. The two banks have a combined capital of \$100,000.

**WILBERFORCE**, *wil'ber-fôrs*, Robert Isaac, English clergyman, 2d son of William Wilberforce (q.v.): b. Clapham, Surrey, 19 Dec. 1802; d. Albano, Italy, 4 Feb. 1857. He was graduated from Oriel College, Oxford, in 1823, and was subsequently chosen Fellow of his college, associating in that capacity with Pusey and Newman, Hurrell Froude and other leaders of the High Church party. In 1830 he left Oxford to take charge of a parish, and became vicar in 1840 of Burton Agnes, Yorkshire. He published 'Church Courts and Discipline' (1843); 'Lucius, or Stories of the Third Age' (1842); 'Doctrine of the Incarnation' (1848); and 'Doctrine of Holy Baptism' (1849), the two last attracting great attention by the very positive doctrines they enunciated. He also published a 'History of Erastianism' (1851); 'Doctrine of the Eucharist' (1852); 'Inquiry into the Principles of Church Authority' (1854), etc. Finding that he could no longer consistently hold his position in the Church of England, he was received into the Roman Catholic Church in Paris in October 1854.

**WILBERFORCE**, Samuel, English prelate, 3d son of William Wilberforce (q.v.): b. Clapham, Surrey, 7 Sept. 1805; d. near Dorking, Surrey, 19 July 1873. He was graduated from Oriel College, Oxford, in 1826, ordained deacon in 1828, and appointed curate of Checkendon, Oxfordshire, the same year. He was rector of Brightstone, in the Isle of Wight, 1830-40, in 1839 became archdeacon of Surrey, and in 1840 a canon of Westminster. In the last-named year also he became rector of Alverstoke, Hampshire. He received the deanery of Westminster in March 1845, but before the close of that year was promoted to the bishopric of Winchester. He was the leader of the High Church party, though much opposed to ritualism, and was both witty and eloquent as well as a skilful debater in the House of Lords. His readiness in argument and his versatile qualities gained him the title of "Soapy Sam." He pub-

lished 'Notebook of a Country Clergyman' (1833); 'Eucharistica' (1839); 'A History of the Protestant Episcopal Church in America' (1844); 'University Sermons,' etc. Consult the 'Life' by his son, R. G. Wilberforce (1888); Daniell, 'Bishop Wilberforce' (1891).

**WILBERFORCE, William**, English philanthropist: b. Hull, Yorkshire, 24 Aug. 1759; d. London, 29 July 1833. Educated at Cambridge, he was in 1780 elected member of Parliament for his native town; and in 1784 was returned both by his former constituency and by the county of York. He chose to represent the latter. In 1786 he made the acquaintance of Clarkson, who gained his sympathies on behalf of the agitation against the slave-trade, to which he henceforth devoted all his energies in Parliament till the agitation proved successful. He first called the attention of the house to the subject in 1787, and in 1791 moved for leave to bring in a bill to prevent further importation of African negroes into the British colonies. Year after year he pressed this measure, but was defeated till 1807, when it was passed during the short administration of Fox. Having secured the abolition of the slave-trade in the British colonies, he addressed himself to the task of obtaining emancipation for those already reduced to or born in slavery. In 1812, after having sat for Yorkshire in six Parliaments, he withdrew from the representation, and until 1825, when he retired from Parliament, sat for the borough of Bramber. He died shortly after the government plan for the total abolition of slavery in the British colonies had passed in the House of Commons. His remains were interred in Westminster Abbey, and his funeral was attended by distinguished men of all parties. Wilberforce was the author of a treatise entitled 'A Practical View of the Prevailing Religious Systems of Professed Christians in the Higher and Middle Classes contrasted with Real Christianity' (1797). Consult 'Life of William Wilberforce' by his sons (1838); his 'Correspondence' (edited 1840); and 'Private Papers of William Wilberforce' (edited 1897).

**WILBERFORCE UNIVERSITY**, an institution for the education of the colored race located at Wilberforce, a suburb of Xenia, Ohio. It was founded in 1856 under the auspices of the African Methodist Episcopal Church. It includes the Collegiate Department, the Normal Department, the Payne Theological Seminary, a Law Department, the Academic Department and Music and Commercial departments, and a Nurses' Training School. Women are admitted to all departments. The Collegiate Department offers two four years' courses, the classical and the scientific leading to the degrees of A.B. and B.S. The Theological Seminary offers a three years' course and confers the degree of B.D. A practice school is connected with the work of the Normal Department. Industrial training is not included in the curriculum; students, however, care for their own rooms. Emphasis is placed upon the development of moral character; there are few rules for behavior and government, but these are strictly enforced. The income in 1917 and recent years has been slight, mostly obtained from tuition fees. The grounds and buildings are valued at over

\$380,000; a new dormitory was built in 1900-01; the library contains nearly 10,000 volumes. The students numbered 455 and the faculty 39 in 1917.

**WILBOUR, Charlotte Beebe**, American woman-suffrage worker: b. East Hartford, Conn., 2 March 1833; d. New York, 25 Dec. 1914. She was educated at the Wilbraham (Mass.) Academy, and was married to Charles E. Wilbour, an Egyptologist, in 1858. She was associated with Susan B. Anthony and Elizabeth Cady Stanton as a worker for suffrage for women, and became known as a public speaker of much force and eloquence. She was one of the founders of the Sorosis Club in New York in 1868, which in 1869 became the first incorporated women's club in the United States. She was president of the club in 1870-75 and in 1903-07, then becoming honorary president. She lived abroad with her husband in 1875-1900.

**WILBUR, wil'ber, John**, American preacher of the Society of Friends: b. Hopkinton, R. I., 17 July 1774; d. there, 1 May 1856. He was a teacher and surveyor, who was a strongly conservative member of the Society of Friends and opposed innovations which he believed to be at variance with the original doctrine of the society. For his alleged statements reflecting on J. J. Gurney (q.v.), the English Quaker, he was denounced by several members of the Rhode Island yearly meeting of 1838. He was sustained by a large majority of his own (South Kingstown) monthly meeting; but that meeting was dissolved and its members added to the Greenwich meeting, by which he was formally disowned in 1843. This action was confirmed by the quarterly meeting and the Rhode Island yearly meeting. Wilbur's adherents then withdrew from the orthodox society in such numbers as to form an independent conservative yearly meeting whose members were styled Wilburites (q.v.). Among Wilbur's writings, largely polemical, was 'A Narrative and Exposition' (1845). His 'Journal and Correspondence' appeared in 1859.

**WILBUR, Ray Lyman**, American physician and university president: b. Boonesboro, Iowa, 13 April 1875. He was graduated at Leland Stanford Junior University in 1896 and received the degree of M.D. at Cooper Medical College, San Francisco, in 1899, later studying at Frankfort-on-the-Main, London and Munich. He was appointed to the chair of medicine at Leland Stanford Junior University in 1909, and also filled the office of dean from 1911; since 1915 he has been president of the university. He was president of the American Academy of Medicine in 1912-13; was appointed chief of the division of conservation of the United States Food Commission in 1917; and in 1917 also became a member of the California State Council of Defense.

**WILBURITES**, a branch of the Society of Friends, or Quakers, who adopted the principles of Rev. John Wilbur (q.v.), and maintain an independent yearly meeting. Wilbur became a preacher of the Society of Friends, and took a strongly conservative stand against what he regarded as innovations antagonistic to the original doctrines of the society. Wilbur's followers in 1918 included 49 ministers, 47

churches, and about 4,000 communicants. See FRIENDS, THE RELIGIOUS SOCIETY OF.

**WILCOX**, wil'kòks, **Cadmus Marcellus**, American soldier: b. Wayne County, N. C., 19 May 1826; d. Washington, D. C., 2 Dec. 1890. He was graduated from West Point in 1846, served in the Mexican War, and in 1860 was promoted captain. In 1861 he resigned from the army and entered the service of the Confederacy. He participated in the first battle of Bull Run, was promoted brigadier-general in October, and in 1863 became major-general. He was engaged in the second battle of Bull Run, at Fredericksburg, Chancellorsville, Salem Heights, Gettysburg and other important battles, and was present at the surrender at Appomattox courthouse. He was offered a commission as brigadier-general in the Egyptian army after the close of the Civil War, but declined it. In 1886-89 he was chief of the division of railroads at the general landoffice in Washington. He wrote 'Rifles and Rifle Practice' (1859); translation 'Austrian Infantry Evolutions of the Line' (1860); and an excellent 'History of the Mexican War,' the manuscript of which was completed and published by his niece, M. R. Wilcox (1892).

**WILCOX**, Delos Franklin, American municipal government expert: b. Ida, Mich., 22 April 1873. He was graduated at the University of Michigan in 1894 and took the degree of Ph.D. at Columbia University in 1896. He edited the *Detroit Civic News* in 1905-07; and in 1907-13 he was chief of the bureau of franchises in the first district of the New York Civil Service Commission; while in 1914-17 he was deputy commissioner of the New York department of water supply, gas and electricity. He is a recognized authority on municipal government and has written extensively on the subject. His works include 'The Study of City Government' (1897); 'Ethical Marriage' (1900); 'The American City' (1904); 'The Government of Great American Cities' (1908); 'Municipal Franchises' (2 vols., 1910-11); 'Great Cities in America' (1910); 'Government by all the People' (1912), etc.

**WILCOX**, Ella Wheeler, American poet: b. Johnstown Centre, Wis., 1855; d. South Beach, Conn., 30 Oct. 1919. She was educated at the University of Wisconsin and in 1884 began her literary career by contributing to the periodical press, and her work has been widely read and extensively reprinted. 'Poems of Passion' (1883) gave her a national reputation. Her verse has been widely published in daily newspapers. In recent years she dealt more and more with subjects pertaining to the higher life, the brotherhood of man, faith in a future life, reincarnation, etc. Among her other publications, in verse, are 'Drops of Water' (1872); 'Maurine and Other Poems' (1876); 'Poems of Pleasure' (1887); 'The Beautiful Land of Nod' (1892), etc. She also wrote the novels, 'Mal Moulée' (1885); 'A Double Life' (1890); 'An Erring Woman's Love' (1892); 'The Story of a Literary Career' (1904); 'Poems of Sentiment' (1906); 'Poems of Progress and New Thought Pastels' (1910); 'Sailing Sunny Seas' (1911); 'Historical Mother Goose' (1914); 'Poems of Problems' (1914); 'The World and I' (1919).

**WILCOX**, Marrion, American author: b. Augusta, Ga., 3 April 1858. He was graduated from Yale in 1878, made special studies at the universities of Oxford, Heidelberg, Jena and Berlin, and was subsequently admitted to the New York bar. He acted as instructor at Yale in 1884-86, was associate editor of the *New Englander* and the *Yale Review*, and since 1893 has been engaged in editorial and other literary work in New York. In 1902 he became noted as an advocate of fair play to Cuba, defending the principle of reciprocity in the United States and urging concessions from the political leaders and economic associations of Cuba. His principles were approximately those embodied in the treaty submitted to Congress and accepted in 1903. In 1906-07 he visited South America and Mexico. In 1907 and especially in Mexico, Brazil and Argentina Mr. Wilcox suggested the interchange of professors between the United States and Latin-American countries. He has published 'Real People' (1886); 'A Short History of the War with Spain' (1898); 'Harper's History of the War in the Philippines' (1900); 'Sketches in Spain, England and Italy,' etc. He contributed many articles on Central and South American topics to the 'Encyclopedia Americana' and edited, in collaboration with George E. Rines, 'The Encyclopedia of Latin-America' (1917). Mr. Wilcox is a contributor to the *North American Review*, the *Churchman*, *Atlantic Monthly*, the *Scientific American*, the *Architectural Record*, and other periodicals.

**WILCOX**, Robert William, American legislator: b. Kuhulu, Honolulu, Hawaii, 15 Feb. 1855; d. Honolulu, Hawaii, 24 Oct. 1903. He was educated in Hawaii and at the Royal Military Academy, Turin, Italy. He was a member of the native legislature, led the revolution to restore the old constitution in 1889, and in 1895 again commanded a revolution, on this occasion for the purpose of restoring Queen Liliuokalani to the throne. He was captured and sentenced to death, but through the mediation of the United States Congress the sentence was commuted to 35 years' imprisonment and \$10,000 fine. He was pardoned, conditionally in 1896, and fully in 1898, by Governor Dole. He was elected a delegate to the United States Congress in 1901 and served one term.

**WILD**, Heinrich, hin'rih vilt, Swiss meteorologist: b. Uster, 17 Dec. 1833; d. Zurich, 5 Sept. 1902. His education was obtained at Zurich, Königsberg and Heidelberg, and from 1863 to 1865 he was director of the central meteorological bureau at Bern. He was called to Saint Petersburg, and was director of the Russian meteorological service 1868-95, when he retired. He invented the polaristrobometer, a polarization pluviometer, a magnetic theodolite and other optical instruments, edited the Russian 'Neues Repertorium für Meteorologie,' and published 'Temperatur-Verhältnisse des russischen Reichs' (1876), and technical papers.

**WILD**, Jonathan, English thief and informer: b. Wolverhampton, England, about 1682; d. London, 24 May 1725. He was a Birmingham buckle-maker who in 1706 went to London intending to engage in his trade, but becoming involved in debt was imprisoned for

four years, after which he became a receiver of stolen goods and an informer against such criminals as were not in his employ. He was hanged at Tyburn. He was the subject of Fielding's satire, 'History of the Life of the Late Mr. Jonathan Wild the Great' (1743), and also appears in Ainsworth's novel, 'Jack Shepherd,' as well as in various other tales and pretended biographies.

**WILD DUCK, The.** Henrik Ibsen, in his ironic play 'The Wild Duck' ('Vildanden'), published in 1884 and performed the year following, sought to exhibit the folly of obedience to any mere formula of conduct, a doctrine already propounded in his early poetic drama, 'Brand.' Incidentally, he made clear the dangers of a shallow idealism, and challenged his admirers to decide each case of conduct on its own merits, rather than according to some nicely worded law discovered in his plays. In 'The Pillars of Society' and 'An Enemy of the People,' Ibsen had insisted that truth and freedom are essential to social welfare; and in 'A Doll's House' he had declared for perfect confidence between husband and wife. Yet in 'The Wild Duck,' he lets us understand that there are instances when "the truth, the whole truth, and nothing but the truth," may work more harm than good.

A busy-body reformer, sincere though short-sighted, finds that his former classmate in college has been wedded to a woman with a past. He discovers that it is his own father who has disgraced her, and feels in duty bound to enlighten Hjalmar Ekdal and convince him of the necessity of beginning life afresh with Gina on a basis of mutual understanding. But no sooner does Hjalmar learn from the idealist reformer that his Gina has once been the mistress of another than he rebuffs her and the innocent child he had thought his own, and proposes to forsake them both. The little girl, having been taught by the meddling idealist the doctrine of self-abnegation, accepts it literally, and, instead of sacrificing only her pet duck to win back Hjalmar's love, sacrifices her dearest possession, life itself. Thus the idealist—Gregers Werle—with the best of intentions, has wrought havoc in a family hitherto happy, though in part deluded.

Quite aside from its central meaning, the play is of interest as depicting with minute fidelity a curious group of characters. Of especial note are the Ekdals, all victims of old Werle. There is the lieutenant, once his partner in a dishonest business, serving in prison as his scape-goat, and emerging to find his only pleasure in hunting pretended game in a pretended forest in an attic. There is the lieutenant's son Hjalmar, ostensibly a photographer, but in fact an idle dreamer assuming poses to deceive himself and others, mouthing conventionally when informed that old Werle has married him to Gina to conceal her fault and his. There is little Hedvig, cursed by her inheritance from old Werle with weak eyes, straining them unduly in touching up negatives for the lazy Hjalmar, for whose sake she mistakenly lays down her life. And there is Gina, loyal and industrious, the embodiment of common sense, little troubled by remorse for her past, yet unconsciously atoning for it

by devotion to her husband and her child. Not the least enigmatic characters are the minor folk Molyvik and Relling, the latter proclaiming the need of every creature for some life-lie, some delusion to make him happy.

Technically, the piece is noteworthy for its decorative and incidental symbolism, an insinuated parallel being drawn between the bird that was shot by old Werle and sunk in the marsh until retrieved and further lamed by his dog; and the Ekdal family, injured by Werle and hurt even more by the efforts of Gregers to redeem it. English versions of 'The Wild Duck' have been made by Mrs. E. Marx-Aveling, Mrs. F. E. Archer and R. F. Sharp.

FRANK W. CHANDLER.

**WILD FLOWERS.** A somewhat indefinite term applied to flowers of plants growing without cultivation, which by reason of their size and colors are conspicuous objects to the ordinary observer.

Plants are grouped by botanists into orders, families and genera. For example, the wild yellow or field lily is known as *Lilium canadense*. *Canadense* is the specific name. *Lilium* is the generic name (*Lilium philadelphicum* being another species belonging to the same genus). *Lilium* belongs to the lily family, *Liliaceæ*, which contains a number of closely related lily-like genera. The lily family in turn belongs to the Order *Liliales*, which contains in addition to the Lily family the Trillium family (*Trilliaceæ*), the Lily of the Valley family (*Convallariaceæ*) and other rather closely allied families.

Some families of flowering plants contain a large number of species, others contain but a few species. The largest families of flowering plants in the northeastern United States are the following:

SUNFLOWER FAMILY.....	( <i>Compositæ</i> ), 511 species.
GRASS FAMILY.....	( <i>Gramineæ</i> ), 378 species.
SEDGE FAMILY.....	( <i>Cyperaceæ</i> ), 333 species.
ROSE FAMILY.....	( <i>Rosaceæ</i> ), 215 species.
PULSE FAMILY.....	( <i>Leguminosæ</i> ), 182 species.
MINT FAMILY.....	( <i>Labiata</i> ), 119 species.
FIGWORT FAMILY.....	( <i>Scrophulariaceæ</i> ), 115 species.
MUSTARD FAMILY.....	( <i>Crucifera</i> ), 102 species.
BUTTERCUP FAMILY.....	( <i>Ranunculaceæ</i> ), 93 species.
HEATH FAMILY.....	( <i>Ericaceæ</i> ), 79 species.
CARROT FAMILY.....	( <i>Umbellifera</i> ), 77 species.
ORCHID FAMILY.....	( <i>Orchidaceæ</i> ), 68 species.

The whole number of species of flowering plants (native and introduced) treated in the last edition of Gray's 'Manual' is 4,079 (including 115 species of ferns and 25 species of Gymnosperms or cone-bearing trees). The number of species treated in Britton and Brown's 'Illustrated Flora' is slightly larger.

The number of wild flowers described and illustrated in the 'Wild Flowers of New York' is slightly less than 400, which does not include all plants with conspicuous or attractively colored flowers, and which might be called "wild flowers."

Small's 'Flora of the Southeastern United States' contains 6,364 species. Rydberg's 'Flora of the Rocky Mountains and the Adjacent Plains' describes 5,897 species, and the total number of species of flowering plants in the United States and Canada is estimated to be between 9,000 and 10,000.

The common wild flowers of the United States are tabulated by regions as follows:

NORTHEASTERN UNITED STATES.	
JACK-IN-THE-PULPIT.....	( <i>Arisaema triphyllum</i> ).
WILD CALLA.....	( <i>Calla palustris</i> ).
PICKEREL-WEED.....	( <i>Pontederia cordata</i> ).
RED, WOOD OR PHILADELPHIA LILY.....	( <i>Lilium philadelphicum</i> ).
WILD YELLOW OR CANADA LILY.....	( <i>Lilium canadense</i> ).
YELLOW ADDER'S-TONGUE, OR DOG'S-TOOTH VIOLET.....	( <i>Erythronium americanum</i> ).
YELLOW CLINTONIA, DOG-BERRY.....	( <i>Clintonia borealis</i> ).
WILD OR FALSE SPIKENARD.....	( <i>Vagnera racemosa</i> ).
BELLWORT.....	( <i>Urtularia grandiflora, perfoliata</i> ).
RED TRILLIUM; WAKE ROBIN.....	( <i>Trillium erectum</i> ).
WHITE TRILLIUM; LARGE-FLOWERED WAKE ROBIN.....	( <i>Trillium grandiflorum</i> ).
PAINTED TRILLIUM.....	( <i>Trillium undulatum</i> ).
BLUE FLAG.....	( <i>Iris versicolor</i> ).
BLUE-EYED GRASS.....	( <i>Nystrichium angustifolium</i> ).
SHOWY LADY'S-SLIPPER.....	( <i>Cypripedium reginae</i> ).
YELLOW LADY'S-SLIPPER.....	( <i>Cypripedium parviflorum, pubescens</i> ).
MOCCASIN FLOWER.....	( <i>Fissipes aculis</i> ).
SHOWY ORCHIS.....	( <i>Galeorchis spectabilis</i> ).
YELLOW FRINGED ORCHIS.....	( <i>Blephariglotis ciliaris</i> ).
WHITE FRINGED ORCHIS.....	( <i>Blephariglotis blephariglotis</i> ).
PURPLE FRINGED ORCHIS.....	( <i>Blephariglotis psycodes, grandiflora</i> ).
GRASS PINK, CALOPOGON.....	( <i>Limodorum tuberosum</i> ).
ARETHUSA.....	( <i>Arethusa bulbosa</i> ).
POGONIA.....	( <i>Pogonia ophioglossoides</i> ).
LADY'S-THUMB.....	( <i>Persicaria pericaria</i> ).
WILD PINK.....	( <i>Silene caroliniana</i> ).
LARGE YELLOW POND LILY.....	( <i>Nymphaea advena</i> ).
SWEET-SCENTED WHITE WATER LILY.....	( <i>Castalia odorata</i> ).
MARSH MARIGOLD.....	( <i>Caltha palustris</i> ).
BANEBERRY.....	( <i>Actaea rubra, alba</i> ).
WILD COLUMBINE.....	( <i>Aquilegia canadensis</i> ).
ANEMONES { WIND ANEMONE.....	( <i>Anemone quinquefolia</i> ).
CANADA ".....	( <i>Anemone canadensis</i> ).
RUE ".....	( <i>Syndesmon thalictroides</i> ).
SPRING BEAUTY.....	( <i>Claytonia virginica, caroliniana</i> ).
HEPATIC.....	( <i>Hepatica hepatica, acutiloba</i> ).
BUTTERCUP.....	( <i>Ranunculus acris, hispidus, septentrionalis</i> ).
EARLY MEADOW RUE.....	( <i>Thalictrum dioicum</i> ).
FALL MEADOW RUE.....	( <i>Thalictrum polygamum</i> ).
VIRGIN'S BOWER.....	( <i>Clematis virginiana</i> ).
BLOODROOT.....	( <i>Sanguinaria canadensis</i> ).
SQUIRREL CORN.....	( <i>Bicuculla canadensis</i> ).
DUTCHMAN'S BRECKLES.....	( <i>Bicuculla cucullaria</i> ).
CRINKLEFOOT, PEPPERROOT.....	( <i>Dentaria laciniata, diphylla</i> ).
PITCHER PLANT.....	( <i>Sarracenia purpurea</i> ).
GRASS-OF-PARNASSUS.....	( <i>Parnassia caroliniana</i> ).
FOAMFLOWER.....	( <i>Tiarella cordifolia</i> ).
MEADOWSWERT.....	( <i>Spiraea latifolia</i> ).
HARDHACK, STEEPLEBUSH.....	( <i>Spiraea tomentosa</i> ).
LOW OR PASTURE ROSE.....	( <i>Rosa virginiana</i> ).
WILD LUPINE.....	( <i>Lupinus perennis</i> ).
GOAT'S RUE, WILD SWEET PEA.....	( <i>Cracca virginiana</i> ).
WILD GERANIUM, CRANE'S-BILL.....	( <i>Geranium maculatum</i> ).
SPOTTED TOUCH-ME-NOT.....	( <i>Impatiens biflora</i> ).
PALE TOUCH-ME-NOT.....	( <i>Impatiens pallida</i> ).
FRINGED MILKWORT.....	( <i>Polygala paucifolia</i> ).
MUSK MALLOW.....	( <i>Malva moschata</i> ).
SWAMP ROSE MALLOW.....	( <i>Hibiscus moscheutos</i> ).
BIRD'S-FOOT VIOLET.....	( <i>Viola pedata</i> ).
YELLOW VIOLET.....	( <i>Viola pubescens, ericarpa</i> ).
COMMON BLUE VIOLET.....	( <i>Viola papilionacea, cucullata, sororia</i> ).
SWEET WHITE VIOLET.....	( <i>Viola blanda</i> ).
CANADA VIOLET.....	( <i>Viola canadensis</i> ).
LONG-SPURED VIOLET.....	( <i>Viola rostrata</i> ).
EVENING PRIMROSE.....	( <i>Oenothera biennis</i> ).
FLOWERING DOGWOOD.....	( <i>Cornus florida</i> ).
LOW OR DWARF CORNELL BUNCHBERRY.....	( <i>Cornus canadensis</i> ).
SHINLEAF.....	( <i>Pyrola elliptica</i> ).
INDIAN PIPE, CORPSE PLANT.....	( <i>Monarda uniflora</i> ).
TRAILING ARBUTUS.....	( <i>Epigaea repens</i> ).
PURPLE OR PINK AZALEA, PINKSTER.....	( <i>Azalea nudiflora</i> ).
MOUNTAIN LAUREL.....	( <i>Kalmia latifolia</i> ).
FRINGED GENTIAN.....	( <i>Gentiana crinita</i> ).
CLOSED GENTIAN.....	( <i>Gentiana andrewsis</i> ).
BUTTERFLY WREED.....	( <i>Asclepias tuberosa</i> ).
COMMON MILKWREED.....	( <i>Asclepias syriaca</i> ).

HEDGE BINDWEED.....	( <i>Convolvulus septium</i> ).
GROUND OR MOSS PINK.....	( <i>Phlox subulata</i> ).
VIRGINIA COWSLIP, BLUE-BELLS.....	( <i>Mercurialis virginica</i> ).
FORGET-ME-NOT.....	( <i>Myosotis scorpioides</i> ).
OSWEGO TEA, BEE BALM.....	( <i>Monarda didyma</i> ).
WILD BERGAMOT.....	( <i>Monarda fistulosa</i> ).
TURTLE-HEAD.....	( <i>Chelone glabra</i> ).
LARGE PURPLE GERARDIA.....	( <i>Gerardia purpurea</i> ).
WOOD BETONY.....	( <i>Pedicularis canadensis</i> ).
BLUETS.....	( <i>Houstonia corymbosa</i> ).
PEARLY EVERLASTING.....	( <i>Anaphalis margaritacea</i> ).
TWINFLOWER.....	( <i>Linnæa americana</i> ).
HAREBELL.....	( <i>Campylopus rotundifolia</i> ).
CARDINAL FLOWER.....	( <i>Loelia cardinalis</i> ).
PURPLE BONESET.....	( <i>Eupatorium purpureum</i> ).
FLAT-TOPPED GOLDENROD.....	( <i>Solidago graminifolia</i> ).
WREATH GOLDENROD.....	( <i>Solidago carnea</i> ).
WHITE OR PALE GOLDENROD.....	( <i>Solidago bicolor</i> ).
CANADA GOLDENROD.....	( <i>Solidago canadensis</i> ).
RED-STALKED ASTER.....	( <i>Aster puniceus</i> ).
NEW ENGLAND ASTER.....	( <i>Aster nova-angliae</i> ).
MOUNTAIN ASTER.....	( <i>Aster acuminatus</i> ).
WHITE DAISY.....	( <i>Chrysanthemum leucanthemum</i> ).
YELLOW DAISY, BLACK-EYED SUSAN.....	( <i>Rudbeckia hirta</i> ).
GREEN-HEADED CONE-FLOWER.....	( <i>Helianthus laciniata</i> ).
TALL, GIANT OR WILD SUNFLOWER.....	( <i>Helianthus giganteus</i> ).
ROCKY MOUNTAIN REGION AND ADJ. PLAINS.	
BEAR GRASS, TURKEY-BEARD.....	( <i>Xerophyllum tenax</i> ).
WHITE CAMAS.....	( <i>Anisoclis elegans</i> ).
WILD HYACINTH.....	( <i>Trillium grandiflora</i> ).
MOUNTAIN LILY.....	( <i>Leucocorynum montanum</i> ).
WESTERN RED LILY.....	( <i>Lilium umbellatum, monnium</i> ).
TIGER LILY.....	( <i>Fritillaria atropurpurea</i> ).
DOG'S-TOOTH VIOLET.....	( <i>Erythronium grandiflorum</i> ).
ALP LILY.....	( <i>Lloydia serotina</i> ).
BLUE CAMAS.....	( <i>Quamoculis quamoculis</i> ).
MARIPOSA LILY.....	( <i>Calochortus spiculatus, acarpus, garrinsonii</i> ).
WESTERN BLUE FLAG.....	( <i>Iris missouriensis</i> ).
UMBRELLA PLANT.....	( <i>Eriogonum, numerous species</i> ).
SAND VERBENA.....	( <i>Abronia fragrans</i> ).
FOUR-O'CLOCK.....	( <i>Ipomoeoidium multiflorum</i> ).
UMBRELLA-WORT.....	( <i>Allotria nycagifera, lanan, etc.</i> ).
BITTER-ROOT, RED-HEAD.....	( <i>Lewisia rediviva</i> ).
LOUISA.....	( <i>Silene acutis</i> ).
MOSS CAMPION.....	( <i>Silene acutis</i> ).
YELLOW POND LILY.....	( <i>Nymphaea polysepala, exalta, etc.</i> ).
PASQUE-FLOWER, WILD CROCUS.....	( <i>Pulsatilla ludoviciana</i> ).
PURPLE VIRGIN'S BOWER.....	( <i>Astragalus columbianus, psadoalpinus</i> ).
MARSH MARIGOLD.....	( <i>Caltha leptosepala</i> ).
GLOBE-FLOWER.....	( <i>Trollius altissimus</i> ).
YELLOW COLUMBINE.....	( <i>Aquilegia flavescens</i> ).
BLUE COLUMBINE (State Flower of Colorado).....	( <i>Aquilegia coarctata</i> ).
LARKSPUR.....	( <i>Delphinium, several species</i> ).
PRICKLY POPPY.....	( <i>Argemone mexicana, hispid</i> ).
YELLOW SAXIFRAGE.....	( <i>Leptasia chrysantha</i> ).
FLOWERING OR GOLDEN CURRANT.....	( <i>Ribes odoratum, auratum</i> ).
MEADOW-SWEET.....	( <i>Spiraea lucida, densiflora</i> ).
DRYAD, MOUNTAIN AVENS.....	( <i>Dryas octopetala</i> ).
WILD ROSE.....	( <i>Rosa macrantha, woodsii, e numerous other species</i> ).
WILD LUPINES.....	( <i>Lupinus, numerous species</i> ).
POMME DE PRAIRIE.....	( <i>Psoralea esculenta</i> ).
PRAIRIE CLOVER.....	( <i>Psacalotomon candidus, p purus, etc.</i> ).
RATTLE-WEED.....	( <i>Phaca americana, longifolia, etc.</i> ).
MILK VETCH.....	( <i>Astragalus canadensis, sp. lat., etc.</i> ).
PINK LADY-FINGER.....	( <i>Xylophacos utahensis</i> ).
VETCHLING.....	( <i>Lathyrus ornatus, vranus, etc.</i> ).
CRANEBILL, WILD GERANIUM.....	( <i>Geranium richardsonii, n casinum</i> ).
WILD HOLLYHOCK.....	( <i>Sidalcea candida</i> ).
SCARLET MALLOW.....	( <i>Sphaeralcea coccinea</i> ).
VIOLET, BLUE.....	( <i>Viola pratensis, rotunda, etc.</i> ).
YELLOW.....	( <i>Viola venosa, longicaulis, nuttallii</i> ).
DOG.....	( <i>Viola adamsii</i> ).
SAND LILY.....	( <i>Monticola albimanis</i> ).
FIRE-WEED.....	( <i>Chamaenerion spicatum</i> ).

WILD FLOWERS

WILD FLOWERS

3. Red Trillium or Wake-robין (*Trillium erectum*)  
- Fringed Gentian (*Gentiana crinita*)

4. Marsh Marigold (*Caltha palustris*)  
8. Near-England Aster (*Aster nemorosus*)

1

.

BABY'S BREATH..... (*Gayophytum diffusum*).  
 EVENING PRIMROSE..... (*Oenothera hookeri, jamesii, etc.*)  
 MOUNTAIN PRIMROSE..... (*Pachylophus caespitosus*).  
 RED OR PURPLE HEATHER... (*Phyllodoce empetriformis*).  
 MOSS-PLANT, WHITE HEATH-ER..... (*Cassiope mertensiana*).  
 PARRY'S MOUNTAIN PRIM-ROSE..... (*Primula parryi*).  
 MOUNTAIN PINK..... (*Douglasia nivalis, montana*).  
 SHOOTING STAR..... (*Dodecatheon multiflorum, phioscia, hendersoni, etc.*).  
 GENTIAN, BLUE..... (*Gentiana parryi, bigelovii, etc.*).  
 " FRINGED..... (*Gentiana thermalis, barbellatus, simplex*).  
 " MOSS..... (*Gentiana fremontii, americana*).  
 AMERICAN COLUMBO..... (*Mertensia, numerous species*).  
 DEER'S-TONGUE..... (*Frasera speciosa*).  
 MILKWEEDS..... (*Asclepias speciosa, latifolia, etc.*)  
 BUSH MORNING GLORY.... (*Ipomaea leptophylla*).  
 WILD SWEET WILLIAM..... (*Phlox longifolia, stansburyi, etc.*)  
 BABY-BLUE-EYES..... (*Nemophila breviflora*).  
 LUNGWORT, BLUEBELLS..... (*Mertensia, numerous species*).  
 VERBENA, VERVAIN..... (*Verbena bracteosa*).  
 BEARD-TONGUE..... (*Pentstemon, numerous species*).  
 MONKEY-FLOWER, YELLOW.. (*Mimulus geyeri, langsdorffii, moschatus*).  
 " CRIMSON. (*Mimulus lewisii*).  
 PAINT-CUP, INDIAN PAINT-BRUSH..... (*Castilleja, numerous species*).  
 LOUSEWORT..... (*Pedicularis racemosa, parryi, etc.*)  
 BELLFLOWER, HAREBELL... (*Campanula parryi, petiolata, etc.*)  
 BLAZING STAR, BUTTON SNAKE-ROOT..... (*Lacinaria squarrosa, punctata, etc.*)  
 GOLDENRODS..... (*Solidago scopolorum, missouriensis, elongata, and several other species*).  
 WILD ASTERS..... (*Aster conspicuus, douglasii, and numerous other species*).  
 FLEABANE..... (*Erigeron simplex, grandiflorus, etc.*)  
 PURPLE CONE-FLOWER.... (*Brauneria angustifolia*).  
 BLANKET-FLOWER..... (*Gaillardia aristata*).  
 ARNICA..... (*Arnica cordifolia, and other species*).  
 SQUAW-WEED, RAGWORT... (*Senecio plattensis, and numerous other species*).

WILD CLOVER..... (*Trifolium variegatum, fimbriatum, etc.*)  
 VETCHLING..... (*Lathyrus polyphyllus*).  
 WOOD SORREL..... (*Oxalis oregana*).  
 SAINT JOHNSWORT..... (*Hypericum scouleri*).  
 YELLOW VIOLETS..... (*Viola glabella, sempervirens, nuttallii*).  
 BLUE VIOLETS..... (*Viola palmstris, adunca*).  
 FIREWEED..... (*Epilobium angustifolium*).  
 CLARKIA..... (*Clarkia pulchella*).  
 WESTERN FLOWERING DOG-WOOD..... (*Cornus nuttallii*).  
 WINTERGREEN..... (*Pyrola bracteata*).  
 RHODODENDRON..... (*Rhododendron californicum*).  
 LABRADOR TEA..... (*Ledum groenlandicum*).  
 SALAL..... (*Gaultheria shallon*).  
 SHOOTING STAR..... (*Dodecatheon latifolium, etc.*).  
 STAR-FLOWER..... (*Trientalis latifolia*).  
 GENTIAN..... (*Gentiana sceptrum*).  
 GLIA..... (*Gilia gracilis, etc.*).  
 COLLOMIA..... (*Collomia grandiflora*).  
 BABY-BLUE-EYES..... (*Nemophila parviflora*).  
 FIDDLE NECK, BUCKTHORN-WEED..... (*Amsinckia lycopsoides*).  
 YERBA BUENA..... (*Micromeria chamissonis*).  
 BLUE-EYED MARY, BLUE-LIPS..... (*Collinsia tenella, parviflora*).  
 TURTLE-HEAD..... (*Chelone nemorosa*).  
 YELLOW MONKEY-FLOWER.. (*Mimulus langsdorffii, dentatus, nasutus*).  
 RED "..... (*Mimulus lewisii, cardinalis, nanus*).  
 PAINTED CUP, INDIAN PAINT BRUSH..... (*Castilleja angustifolia, etc.*).  
 HONEYSUCKLE..... (*Lonicera ciliosa, hispidula, etc.*).  
 VALERIAN..... (*Valeriana sitchensis*).  
 HAREBELL..... (*Campanula scouleri, rotundifolia*).  
 HAWKWEED..... (*Hieracium albiflorum*).  
 GUM-PLANT, RESIN-WEED.. (*Grindelia oregana*).  
 GOLDENROD..... (*Solidago elongata, etc.*).  
 FLEABANE..... (*Erigeron speciosus, philadelphicus, etc.*).  
 ASTER..... (*Aster douglasii, majow, etc.*).  
 TARWEED..... (*Madia dissitiflora*).  
 YARROW..... (*Achillea lanulosa*).  
 ARNICA..... (*Arnica mollis, cordifolia*).  
 BALSAM-ROOT..... (*Balsamorhiza sagittata*).  
 SWEET COLTSFOOT, BUTTER-BUR..... (*Petasites speciosa*).  
 GROUNDSEL, RAGWORT... (*Senecio triangularis*).  
 PEARLY EVERLASTING..... (*Anaphalis occidentalis*).

THE NORTHWEST.

(Oregon, Washington and British Columbia).

BRODIAEA..... (*Hookera coronaria*).  
 WESTERN RED LILY..... (*Lilium columbianum*).  
 LEOPARD LILY..... (*Fritillaria lanceolata*).  
 DOG'S-TOOTH VIOLET..... (*Erythronium grandiflorum*).  
 WHITE HELLBORE..... (*Veratrum californicum*).  
 PINE LILY, BEAR GRASS... (*Xerophyllum tenax*).  
 WAKE ROBIN..... (*Trillium ovatum*).  
 TWO-LEAVED SOLOMON'S SEAL..... (*Unifolium kamtschaticum*).  
 BLUE FLAG, IRIS..... (*Iris tenax, missouriensis*).  
 CALYPSA..... (*Cytherea bulbosa*).  
 RATTLE-SNAKE PLANTAIN.. (*Peperomia decipiens*).  
 WOOD ORCHIS..... (*Piperia elegans*).  
 BOG ORCHIS..... (*Limnorchis dililiata*).  
 WILD GINGER..... (*Asarum caudatum*).  
 SPRING BEAUTY..... (*Claytonia sibirica, parvifolia*).  
 WILD PINK..... (*Silene menziesii, scouleri, douglasii*).  
 YELLOW POND LILY..... (*Nymphaea polysepala*).  
 TRAUTVETTERIA..... (*Trautvetteria grandis*).  
 COLUMBINE..... (*Aquilegia formosa*).  
 LARKSPUR..... (*Delphinium menziesii, simplex, columbianum*).  
 ACONITE, MONKS-HOOD.... (*Aconitum columbianum*).  
 OREGON GRAPE..... (*Berberis aquifolium, repens*).  
 VANILLA-LEAF..... (*Achlyis iriphylla*).  
 POAM FLOWER..... (*Tiarella trifoliata*).  
 MITERWORT..... (*Tellima grandiflora, parviflora, Lepias menziesii*).  
 RED-FLOWERING CURRANT.. (*Ribes sanguineum*).  
 SYRINGA..... (*Philadelphus gordonianus*).  
 OCEAN SPRAY..... (*Schizoneilus discolor*).  
 WESTERN HARDHACK..... (*Spiraea douglasii*).  
 DEWBERRY..... (*Rubus macropetalus*).  
 SALMONBERRY..... (*Rubus spectabilis*).  
 THIMLEBERRY..... (*Rubus parviflorus*).  
 WILD ROSE..... (*Rosa nutkana, gymnocarpa, pisocarpa*).  
 INDIAN PLUM..... (*Osmaronia cerasiformis*).  
 WILD LUPINE..... (*Lupinus columbianus, polyphyllus, micranthus*).

SOUTHERN STATES.

(Excluding for the most part those of the Northern States which extend southward in distribution).

YELLOW-EYED GRASS..... (*Xyris flexuosa, fimbriata, etc.*).  
 SPIDERWORT..... (*Tradescantia virginiana, montana, etc.*).  
 TURKEY-BEARD..... (*Xerophyllum asphodeloides*).  
 BLAZING STAR..... (*Chamaelirium luteum*).  
 BUNCH-FLOWER..... (*Melanthium latifolium*).  
 WOOD LILY..... (*Lilium calesbaei, grayi, etc.*).  
 WILD HYACINTH..... (*Quamasia hyacinthina*).  
 BEAR GRASS, SPANISH BAYONET..... (*Yucca filamentosa, gloriosa, etc.*).  
 WAKE ROBIN, YELLOW " RED..... (*Trillium luteum*).  
 COLIC-ROOT, STAR-GRASS.. (*Trillium underwoodii, vaseyi*).  
 ATAMASCO LILY..... (*Aletris farinosa*).  
 PRAIRIE LILY..... (*Atamosco alamasco*).  
 VIOLET IRIS..... (*Cooperia drummondii*).  
 TREE ORCHIS..... (*Iris verna*).  
 DOG-TONGUE..... (*Epidendrum cochleatum, etc.*).  
 WILD PINK, FIRE PINK... (*Bletia verecunda*).  
 SHRUB YELLOW-ROOT..... (*Eriogonum tomentosum*).  
 BLACK SNAKE-ROOT..... (*Silene caroliniana, virginica*).  
 LEATHER-FLOWER..... (*Xanthorrhiza apiifolia*).  
 LAUREL, BULL BAY..... (*Cimicifuga racemosa*).  
 SWEET BAY..... (*Viorna viorna*).  
 WATCHES, TRUMPETS..... (*Magnolia foetida*).  
 HYDRANGEA..... (*Magnolia virginica*).  
 MOCK ORANGE, SYRINGA... (*Sarracenia flava*).  
 GOAT'S-BEARD..... (*Hydrangea arborescens, radicata, etc.*).  
 PRAIRIE OR CLIMBING ROSE. (*Philadelphus inodorus, hirsutus, etc.*).  
 CHEROKEE ROSE..... (*Aruncus aruncus*).  
 YELLOW-WOOD..... (*Rosa setigera*).  
 RATTLE-BOX..... (*Rosa cherokeensis*).  
 WISTARIA..... (*Cladastis lutea*).  
 ROSE ACACIA..... (*Crotalaria sagittalis*).  
 LEAD-PLANT..... (*Wistaria frutescens*).  
 BUTTERFLY PEA..... (*Robinia hispida*).  
 (Including *Amorpha fruticosa*, *Bradburia virginiana*, *Citrois maritima*).

 FALSE LADY'S-SLIPPER..... (*Epipactis gigantea*).  
 CALIFORNIA PITCHER PLANT. (*Darlingtonia californica*).

**Bibliography.**—A knowledge of the fundamentals of botany, especially the structure of flowers, is necessary for a broad acquaintance with the wild flowers. For this purpose the following textbooks may be consulted: Gray, A., 'Lessons in Botany'; Curtis, 'Nature and Development of Plants'; Stevens, 'An Illustrated Guide to the Flowering Plants'; Atkinson, 'Elementary Botany'; Coulter, 'Plant Structures'; Willis, 'Practical Flora for Schools and Colleges'; Bergen, 'Botany, Key and Flora'; Jepson, 'School Flora for the Pacific Coast.'

The student interested in the subject of wild flowers in the United States and Canada may refer to some of the following books for fuller information: Bailey, William Whitman, 'New England Wild Flowers and Their Seasons'; id., 'Among Rhode Island Wild Flowers'; Blanchon, Neltje, 'Wild Flowers'; id., 'Nature's Garden'; Creevey, Carolina A., 'Flowers of Field, Hill and Swamp'; id., 'Harper's Guide to Wild Flowers'; Dana, Mrs. William Starr (Frances Theodora), 'How to Know the Wild Flowers'; Davidson, Alice M., 'California Plants in their Homes'; Dowd, Alice M., 'Our Common Wild Flowers of Springtime and Autumn'; Gibson, William Hamilton, 'Our Native Orchids'; Goodale, George L., 'Wild Flowers of America'; Henshaw, Julia W., 'Mountain Wild Flowers of America'; House, Homer D., 'Wild Flowers of New York'; Lounsbury, Alice, 'Guide to the Wild Flowers'; id., 'Southern Wild Flowers and Trees'; Mathews, F. Schuyler, 'Familiar Flowers of Field and Garden'; id., 'Field Book of American Wild Flowers'; Meehan, Thomas, 'The Native Flowers and Ferns of the United States' (2 series, 4 vols., 1878-80); Parsons, Mary E., 'Wild Flowers of California'; Ramaley, Francis, 'Wild Flowers of Colorado'; Reed, Chester A., 'Wild Flowers East of the Rockies'; Thayer, (Mrs.) Emma, 'Wild Flowers of Colorado.'

For the more advanced student who desires to have at hand complete floras of the various regions with which any plant may be determined by the aid of analytical keys, the following books are suggested:

*Eastern United States.*—Britton, N. L., 'Manual of the Flora of the Northern States and Canada'; Britton and Brown, 'Illustrated Flora of the Northern United States and Canada' (3 vols.); Robinson and Fernald, 'Gray's Manual of Botany' (ed. 7).

*Southern United States.*—Chapman, 'Flora of the Southern United States'; Small, 'Flora of the Southeastern United States'; Coulter, 'Botany of Western Texas.'

*Rocky Mountain Region.*—Coulter, 'New Manual of Botany of the Central Rocky Mountains' (revised by Aven Nelson, 1909); Brown and Schäfer, 'Alpine Flora of the Canadian Rocky Mountains'; Rydberg, 'Flora of the Rocky Mountains and Adjacent Plains.'

*Northern Pacific Coast Region.*—Howell, 'Flora of Northwestern America'; Piper, 'Flora of the State of Washington.'

*California.*—Abrams, 'Flora of Los An-

geles and Vicinity'; Jepson, 'Flora of California'; id., 'Flora of Middle Western California.'

HOMER D. HOUSE,  
*State Botanist, The University of the State of New York.*

**WILD HUNT** (Ger. *Wilde Jagd*; also *Wüthenheer*), in German folk-lore, a fancied noise in the air at night, most usually supposed to be heard between Christmas and Epiphany. The sound is compared to that of a spirit host rushing along, accompanied by the shouting of huntsmen and the baying of dogs. The root of the notion is thought to lie in the Christian degradation of the old heathen gods. Like Odin, the lord of all atmospheric and weather phenomena, and consequently of storms, the wild huntsman also appears on horseback in hat and cloak accompanied by a train of spirits—by the ghosts of drunkards, suicides and other malefactors, often without heads or otherwise mutilated. When he comes to a crossroad, he falls, and gets up on the other side. Generally he brings hurt or destruction, especially to any one rash enough to address him or join in the hunting cry, as many persons valiant in their drink have done. Whoever remains standing in the middle of the highway, or steps aside into a tilled field, or throws himself in silence on the earth, is supposed to escape the danger. In many districts heroes of the older or of the more modern legends take the place of Odin: thus, in Lusatia, Dietrich of Bern; in Swabia, Berchtold; in Sleswick, King Abel; in Lower Hesse, Charles the Great; in England, King Arthur; in Denmark, King Waldemar. The legend has in recent times attached itself to individual sportsmen, who, as a punishment for their immoderateness or cruelty in sport, or for hunting on Sunday, were condemned henceforth to follow the chase by night. In lower Germany there are many such stories current of one Hakkelberend, whose alleged tomb is shown in several places.

Another version of the wild hunt is to be found in the legend prevalent in Thuringia. There the procession, formed partly of children who had died unbaptized, and headed by Frau Holle or Holda, passed yearly through the country on Holy Thursday, and the assembled people waited its arrival, as if a mighty king were approaching. An old man with white hair, the faithful Eckhart, preceded the spirit-host to warn the people out of the way. In one form or other the legend of the wild hunt is spread over all German countries, and is found also in France and even in Spain. In England we meet substantially the same notion in folk-lore—phantom dogs, like the black Shuck-dog of Norfolk and the Mauthe hound of Peel in Man, the "Wisht Hounds" of Dartmoor, headless horses, a ghostly coach and horses swept along in a storm of wind. Such tales, with innumerable variants, are found in the mythical and legendary records of all the older peoples.

**WILD IRISH GIRL**, *The*, a novel by Lady Morgan, published in 1806. It instantly became a favorite in England, went through seven editions in less than two years, and in 1807 reached its fourth American edition. The story is in the form of letters and suffers from

the consequent limitations; but the sketches of Irish life are curious and picturesque.

**WILD LIFE, Conservation of, in America.** Nothing in the New World impressed the first American explorers more than the abundance of its animal life. Early accounts of the country and its resources are filled with rejoicing over the plenitude of its fishes in both the sea and the inland waters; and of the edible or otherwise useful creatures of forest and plain, especially fur-bearers. During the first century of colonization the fisheries and the fur-trade engaged a large part of the population, and all were utterly unrestrained in their drafts on what seemed to them an inexhaustible wealth. This reckless destruction of American animal life, for the sake mainly of pelts or hides, continued as civilization penetrated to the interior until finally not only beasts of prey but the valuable beaver and marten, the wapiti and other deer, and the bison, antelope and bighorn sheep were all but exterminated, various game-birds and waterfowl were depleted and many of the most important fishes, especially those of anadromous species, like the salmon and shad, were nearly destroyed. The wild pigeon is only a conspicuous example of a dozen or more species of useful or beautiful birds that have become totally extinct, and many more have been saved only at the last moment by the strenuous efforts of men who fought the ignorance and greed of lawless gunners and fishermen, often at the peril of their lives. The loss to this country and to Canada (included in this survey) has been incalculable. It is true that a large part of it was inevitable, for it is impossible to civilize a region and maintain the whole of its animal life, much of which could not survive the changed conditions apart from any enmity of man; but the needless waste has been prodigious and sinful. Nevertheless, it is only within a comparatively recent time that even the wisest men of America have awakened to the importance of preserving what remains of the continent's wild life.

Regulative efforts began to be made in the 18th century in the older Eastern States by local laws forbidding shooting in the breeding season, the taking of fish on their spawning-grounds, or on their way thereto, and conserving certain fur-bearers, but these regulations were local and related almost wholly to animals of market value. Gradually these enactments were copied in newer western and southern communities, and were broadened in scope, yet had only a limited effect, partly because they were far from uniform even in adjoining States and were weakened by many exceptions, but mainly because they were not, and perhaps could not, be well enforced, for the people generally were not interested or even felt an inherited prejudice against "game laws" of any sort.

The first popular alarm was felt when, in the middle of the last century, the governments of both the United States and Canada discovered that the decline in the fisheries had reached a danger-point. This led to the making of more stringent laws and their better enforcement, particularly on the Great Lakes. Accompanying this revival of effort scientific studies of food-fishes were promoted by the governments, which resulted in learning how

to propagate fishes artificially on a commercial scale, and thus restock depleted waters. With this movement, by which alone the fisheries of the Great Lakes and other inland waters have been maintained, the name of Soencer F. Baird (q.v.) is permanently associated. These methods, protected by stringent laws and policing, have kept a supply of shad, salmon and other anadromous fishes in our rivers; and sensible regulations are preserving the great sea-fisheries for cod, herring, mackerel and many southern species. Similarly the small lake and river fishes of local food value, or interesting to anglers, are now fairly well protected and replenished under the watchful care of State commissions and various anglers' associations. Regulative care is preserving well also the oyster, clam, crab and other shellfish supply.

Public sentiment and legal control had been steadily improving and were stimulated by the sudden perception, about 1875, that the bison, the wild pigeon, the prairie chicken and other well-known animals would soon become extinct unless rescued. At this time, too, sprang up the world-wide fashion of using stuffed birds, and their wings and feathers, in millinery. Ruthless slaughter of egrets, hummingbirds and every sort of song-bird as well as larger kinds began; and in 1885 the Audubon Society was organized to try to stem the tide of destruction and bring to the minds of women a knowledge of the economic as well as moral wrong involved in the fashion that was sacrificing bird-life all over the world. Out of this movement grew the National Association of Audubon Societies (q.v.), which has been the most powerful factor in bringing all the birds of the country under the protection of good laws. Finally, it was largely instrumental, in co-operation with the United States Biological Survey and several sportsmen's organizations, in arranging a treaty with Canada covering the safety of migratory birds equally in both countries. This treaty, the way for which was paved by the United States Federal law of 1913, protecting all migratory birds, regardless of State lines, was finally ratified in 1916—abolishing in this respect international lines—by the Congress of the United States and by the Parliament of the Dominion of Canada, both of which bodies arranged for its enforcement. The conservation of American bird-life may now be said, therefore, to be in a satisfactory condition.

Meanwhile, under the sympathetic encouragement of President Roosevelt, continued by his successors, certain areas have been set apart from the public domain—in most cases tracts virtually useless for agriculture or grazing—as "Reservations" wherein the destruction of all living and harmless creatures is prohibited. This policy began with the seclusion of the animals of the Yellowstone, Glacier, Mount Olympus and other national parks. But these mountainous and forested places were not suited to the larger plains-animals, for which special reservations were soon prepared. This policy began with the Wichita National Game Preserve in southeastern Oklahoma, covering 57,120 acres. It contains a fenced bison-range of 9,700 acres, which in 1908 was stocked with a band of bisons by the New York Zoological Society; this band has since increased to nearly

100, and many antelopes and deer have been set free in similar great enclosures. Another bison-range was established in northern Montana and stocked in 1910 by the Bison Society, and a large herd is now in existence there. Minnesota has a great deer-preserve in a region of forest, ponds and rocks adjacent to the Canadian line; and a similar refuge for deer exists under State guardianship in the Adirondacks. Greater in extent than all these combined is the grand Canyon National Game Preserve, which embraces the whole region through which the Grand Canyon of the Rio Colorado has been carved. Its area is 2,333 square miles of mountains, plateaus and canyons inhabited by animals that are adapted to the local conditions and could hardly be preserved elsewhere.

For birds about 70 areas have been reserved, including many breeding resorts of sea-birds on the coasts of the Pacific States, British Columbia and Alaska, heretofore raided by egg-hunters; large areas of marshes and lakes in the Pacific States and in the interior necessary as breeding- and feeding-places for western wildfowl and secure refuges for them on their migrations; and many heronries and resorts of shore-birds and ducks in Florida and elsewhere along the Gulf Coast. Similar reservations have been created in Canada and in the insular possessions of the United States. Besides this several of the States, and Provinces have established reserves for animals—notably New York, Pennsylvania, Minnesota, Louisiana and the northern Rocky Mountain States; and in Canada, Quebec, Ontario, Manitoba and Alberta. The Canal Zone is as a whole a bird-reservation; this is the only American one not controlled by the Department of Agriculture and administered by the Biological Survey. It must not be forgotten, also, that the conscientious enterprise of out-door societies of various kinds and of individual citizens have made many private game-preserves and bird-sanctuaries, and in so doing have not only provided local refuges, but have interested and educated the people of the neighborhood. The education of the young and the general interest now felt in animal life in a scientific as well as a humane way is really the greatest safeguard wild life has.

In addition to the federal supervision now exercised in both the United States and Canada to prevent the waste of wild life while enjoying its proper utilization, every State and province has a board of commissioners charged with the same duty, and with the execution of the game laws. These public officials are both aided and criticized by several vigorous organizations, the most powerful of which are The American Game Protective and Propagation Association, The Wild Life Protective Association, The New York Zoological Society, The National Association of Audubon Societies, The Camp Fire Club of America and The Boone and Crockett Club. To this list might well be added the names of a large number of lesser organizations exerting a most useful vigilance and influence locally. Consult the publications of the United States Department of Agriculture, especially those of the Biological Survey and of the Canadian Conservation Commission; also the annual reports of the

State game and fish commissions and of the societies listed above. The best guide to further study, and summary of results up to the beginning of the Great War, is to be found in William T. Hornaday's 'Our Vanishing Wild Life' (New York 1913).

ERNEST INGERSOLL.

**WILDBAD-GASTEIN**, vilt'bäd gäs'tin, Austria, a watering-place in Gastein valley, 3,000 feet above the sea, 48 miles south of Salzburg, with thermal springs varying from 64° to 100°, and containing some salt and carbonates of magnesia and lime. The place gives the name to a treaty signed here in 1865 by the emperor of Austria and the king of Prussia, the non-observance of the terms of which led to the German War of 1866.

**WILDCAT**, any of the smaller species of feline animals (family *Felidae*, q.v.) in its feral condition; a lynx. The term is a general one applying to all the smaller felines; but locally has usually some specific application. Thus in European books and speech the "wildcat" properly and ordinarily means *Felis catus*, formerly well known in all forested districts from the British Isles to Siberia, and still to be found in the less settled districts of the Continent south of Sweden, though extinct in Great Britain, France and Italy; it is also numerous in northern Scotland. The wildcat is larger, heavier and more strongly built than the domestic cat (to which it has contributed little, if anything; see CAT), has a stouter head and shorter and thicker tail, which does not taper; besides other peculiarities. Its body is yellowish gray, with a dark stripe along the spine, and with numerous darkish stripes descending more or less vertically down the sides, marking the limbs transversely and forming rings around the tail. It is noted for its savagery, and thoroughly tamed examples are very rare, if any ever existed. Like most of the wild felines the female makes her nest in a hollow tree, or cleft of rocks, in an abandoned crow's nest, or some similarly convenient place, and brings forth there in early summer an annual litter of young, which show the ferocity of their native disposition from the start.

**Lynxes**.—The other European wildcat and the North American wildcats are lynxes, formerly set apart in a separate genus (*Lynx*); but most modern zoologists do not do so. "The lynxes," says Mivart, "are animals which present a markedly different aspect from that of other cats. Their legs are long, and their tail is, with one exception (that of the caracal), very short. Their ears also are tufted at the tip: The pupil is linear when contracted. The orbits are incompletely surrounded by bone. They have no tooth representing the common cat's first upper premolar, while that answering to its second upper premolar is largely developed. The intestines are also very short. . . . Still the above given characters are variable in the cat group. In some cats other than lynxes the tail is short, and some have the ears more or less penciled. Some, as we have seen, have long legs, and in many the upper premolar is wanting. The lynxes, therefore, cannot be separated off as a nominally distinct group of genus. The lynxes are very variable in their color and markings, and the Northern lynx also varies greatly in the abundance of its hair,

EUROPEAN WILDCAT (*Felis Catus*)

fur is dark-brown above, each hair tipped with white, and it is spotted white on the lower parts, with yellow lines forming a V on the face. Central Asia has several notable wildcats, as the manul (*F. manul*), the steppe cat (*F. caudatus*), and Tibetan tiger-cat (*F. scripta*), all of which are handsomely striped or spotted, or both.

**American Tropical Cats.**—South and Central America are the home of a large variety of small felines, as well as of the puma and jaguar. Of these the most notable are the eyra, ocelot, and jaguarondi (qq.v.) elsewhere described. In addition to these are several of much local interest. The margay or chati (*F. tigrina*) is a widespread and variable species, which is met with from Mexico to Paraguay, in warm and well-wooded lowland regions. Its fur may be a grizzled gray, or vary from that to a fox-red, profusely marked with black spots and rings, which extend along the tail, but do not form rings. There are three upright bars upon each cheek. The margay measures about two feet in length of body, and its tail about 11 inches. Geoffroy's cat (*F. guigna*) is a little known species of southern Brazil. The Pampas cat or straw-cat (*F. pajeras*) is a well-marked form. It is much larger and more robust than a house-cat, with short thick legs, a short, club-shaped tail, thick neck and small head, with great round eyes and very small ears. This appearance of weight and size is largely due to the unusual length of the hair, which is yellowish gray, marked with transverse brownish bands on the body, patches on the face and rings around the tail. It inhabits the open plains of Argentina, and with similar habits has become a curious counterpart of the manul of the Asiatic steppes.

**WILDE**, wild, **George Francis Faxon**, American naval officer: b. Braintree, Mass., 23 Feb. 1845. He was graduated from the United States Naval Academy in 1864 and in 1864-66 was attached to the Brazil squadron. He received promotion to lieutenant-commander in 1869, to commander in 1885, and while commanding the dispatch boat *Dolphin* in 1885-88 made a trip around the world, the *Dolphin* being the first steel vessel in the United States navy to accomplish that feat. He became captain in 1898, commanded the ram *Katahdin* in the Spanish-American War and later, in command of the *Boston*, he landed the first marine troops ever landed in China, sending them to guard the legation at Peking. He captured Iloilo in the Philippine Islands in 1899, and was placed in command of the *Oregon* in that year. In 1900 he captured Vigan in the Philippines, and he was in command of the *Oregon* when she was grounded on an uncharted ledge of rock in the Pechili Gulf. In 1901-02 he was in command of the navy yard at Portsmouth,

N. H., and after 1902 was in charge of the yard at Boston.

**WILDE**, **Jane Francesca Elgee**, **LADY** ("SPERANZA"), Irish poet: b. Wexford, Ireland, 1826; d. Chelsea, England, 3 Feb. 1896. She was married to Sir William Robert Wills Wilde in 1851. Her literary career began in 1845 with her contributions in prose and verse to the 'Nation.' The publication of her essay 'Jacta alea est,' under her pen-name "Speranza," was made the basis of the unsuccessful prosecution of the editor after the suppression of the *Nation* in 1848. Among her writings are 'Ugo Bassi' (1857); 'Poems by Speranza' (1871); 'Ancient Legends, Mystic Charms, and Superstitions of Ireland' (1887); 'Notes on Men, Women and Books' (1891); 'Social Studies' (1893), etc.

**WILDE**, **Oscar** (**Fingal O'Flahertie Wills**), Irish poet: b. Dublin, Ireland, 1856; d. Paris, 30 Nov. 1900. His father was Sir William Wilde, a noted surgeon, and his mother was Lady Jane Wilde (q.v.). He was graduated from Oxford in 1878, winning the Newdigate prize for English verse. In 1879 he went to live in London, where he soon became the leader of the so-called æsthetic movement and was satirized by Du Maurier as 'Postlethwaith' in *Punch*, and by Gilbert in the opera 'Patience.' He visited the United States in 1882, lecturing extensively on art topics, and later lectured similarly in his own country and in Paris. As an orator he was a flat failure, but he had a faculty of keeping himself in the public eye. His poetry and plays constitute his best claim to recognition. In 1895 he was convicted of a serious moral offense and condemned to penal servitude for two years. During his imprisonment he wrote 'A Ballad of Reading Gaol,' a poem of great force, and 'De Profundis,' published in 1905. After his release he lived mainly in France. His other published works include 'Poems' (1880); 'The Picture of Dorian Gray,' a novel; 'The Happy Prince and Other Tales' (1888); the tragedies 'Guido Ferranti' (1890), and 'The Duchess of Padua'; 'Intentions,' essays (1891); 'Lord Arthur Savile's Crimes, and Other Stories' (1891); 'Lady Windermere's Fan,' 'A Woman of No Importance,' and 'The Importance of Being Earnest,' etc. His comedies are extremely clever, and his poems are characterized by melody of movement and beauty of thought. A complete edition of his poems appeared in 1903. Consult Ransome, A., 'Oscar Wilde: a Critical Study' (London 1912); Douglas, Lord Alfred, 'Oscar Wilde and Myself' (New York 1914); Mason, S., 'Bibliography of Oscar Wilde' (London 1914).

**WILDE**, **Richard Henry**, American scholar: b. Dublin, Ireland, 24 Sept. 1789; d. New Orleans, La., 10 Sept. 1847. He came with his parents to the United States in 1797 and settled in Georgia, where he studied law, and in 1809 was admitted to the bar. He was elected attorney-general of his State, and in 1815-17, 1824-25 and in 1827-35 was a member of Congress. He spent the years 1835-40 in Europe, made a special study of Dante and Tasso, and was instrumental in the discovery of a portrait of Dante by Giotto on the wall of the chapel of Bargello. He subsequently

removed to New Orleans, re-engaged in law practice, and in 1844 accepted the chair of constitutional law at the Louisiana State University. He wrote the widely popular poem, 'My Life is Like the Summer Rose,' and also published 'Conjectures and Researches Concerning the Love, Madness and Imprisonment of Torquato Dante' (1842). His poem 'Hesperia,' edited by his son, was published in 1867.

**WILDE, Thomas.** See TRURO, THOMAS WILDE, BARON.

**WILDER, wil'der, Alexander,** American physician and author; b. Verona, N. Y., 14 May 1823; d. 19 Sept. 1908. He was graduated at Syracuse Medical College in 1850, and in 1852 began an editorial career on the *Syracuse Star* being subsequently connected with the *Syracuse Journal* (1853), *New York Teacher* (1856), and *New York Evening Post* (1858-71). He was an anti-Tweed alderman in New York in 1872, inspector of schools in 1873, and from 1875 to 1895 secretary of the National Eclectic Medical Association, editing 19 volumes of 'Transactions.' He was president of the New York School of Philosophy. Among his published works are 'Secret of Immortality Revealed' (1846); 'Neo-Platonism and Alchemy' (1869); 'Our Darwinian Cousins' (1873); 'Eleusinian and Bacchic Mysteries' (1874); 'Ancient Symbol Worship' (1874); 'Serpent and Siva Worship' (1875); 'Vaccination, a Fallacy' (1879); 'Psychology as a Science' (1884); 'The Soul' (1884); 'Higher Sources of Knowledge' (1884); 'Ethics and Philosophy of the Zoroasters' (1885); 'Ancient Symbolism and Serpent Worship' (1886); 'Later Platonists' (1887); 'Antecedent Life' (1895); 'The Ganglionic Nervous System' (1900); 'Perennial Life' (1902); 'History of Medicine' (1902). He translated and edited 'Iamblichus on Egyptian Mysteries.'

**WILDER, Burt Green,** American scholar and physiologist; b. Boston, Mass., 11 Aug. 1841. He was graduated from the Lawrence Scientific School at Harvard in 1862, was assistant surgeon in the Union army in 1863-65, and in 1866 was graduated from the medical department at Harvard. He was assistant in comparative anatomy at the Harvard Museum of Comparative Zoology in 1866-67, and in 1867 accepted the chair of zoology at Cornell, which he occupied until 1916, when he was made professor emeritus. In 1874-84 he was lecturer in physiology at the Summer Medical School of Maine. He has made many interesting researches concerning the habits of the spider, and spent much time in an endeavor to secure a simple anatomic nomenclature. In 1885-86 he was president of the American Neurological Association. He has written numerous professional papers, and much miscellaneous literature, besides several hymns and music, and has published in book form 'What Young People Should Know' (1874); 'Health Notes for Students' (1883); 'Physiology Practicum' (1888); 'Health Notes for Students' (1890); 'History of 55th Mass. Infantry' (1918). His best known music is 'The Founders' Hymn' (1907); 'Slumber Song' (1908); 'Last Night' (1909), and 'Old Ironsides' (1912).

**WILDER, Marshall Pinckney,** American horticulturist; b. Rindge, N. H., 22 Sept. 1798; d. Boston, Mass., 16 Dec. 1886. He was engaged as a merchant in the West India trade at Boston after 1825, in 1839 was chosen to the State legislature, was president of the State senate in 1850, and in 1849 served as member of the executive council. He was prominent in the organization of the Constitutional Union Party, was a delegate to the convention which nominated Bell and Everett in 1860, and throughout the Civil War was a firm supporter of the Union. He founded the Massachusetts Agricultural Society, the Massachusetts Agricultural College, and was active in the movement which resulted in the establishment of the Massachusetts Institute of Technology. He was author of numerous articles on horticulture, and lectured extensively on the subject. Among his published addresses may be mentioned 'The Hybridization of the Camellia and Its Varieties' (1847).

**WILDER, Marshall Pinckney,** American professional entertainer; b. Geneva, N. Y., 19 Sept. 1859; d. 10 Jan. 1915. His occupation was at first a peddler, and later a stenographer, but he abandoned it in order to become a drawing-room entertainer, in which capacity he became widely popular. Though a hunchback he possessed such a pleasing presence with unflinching good humor that he made friends everywhere. At first he entertained for 50 cents an evening, but in 1883 he went to London, was well received by royalty, and his fame was thus established. In 1899 he began to appear in vaudeville. In 1904-05 he toured around the world. He has published 'People I've Smiled With'; 'The Sunny Side of the Street' (1905); 'Smiling Around the World' (1907).

**WILDERNESS, The Battle of the.** On 9 March 1864 President Lincoln handed to General Grant his commission as lieutenant-general and two days later placed him in command of all the armies of the United States. Grant made immediate preparations for an early campaign to be conducted simultaneously, east and west. He made his headquarters with the Army of the Potomac. Before coming to the East he had expressed himself as favoring a coast movement south of James River, and an advance on Richmond on that line. After his arrival at Washington and a study of the problem he proposed to act with the Army of the Potomac on what was known as the overland route from the Rapidan to the James, while General Butler, with 30,000 men, should ascend James River from Fort Monroe and establish himself in an entrenched position near City Point, whence he could operate against Richmond and its communications with the south, and at a proper time form a junction with the Army of the Potomac, moving down from the north. At the same time General Sigel, commanding troops in West Virginia and the Shenandoah Valley, was instructed to form two columns, one of 10,000 men, under General Crook, to move from the Kanawha and operate against the Virginia and East Tennessee Railroad, the other 7,000 strong, under Sigel, in person, to advance, as far as possible, up the Shenandoah Valley, to draw detachments from Lee. Grant's main reliance, however, was the

f the Potomac, which, 30 April 1864, posed of the Second, Fifth and Sixth f infantry and a cavalry corps, respectively by Gens. W. S. Hancock, Warren, John Sedgwick and P. H. Sheridan. The Ninth corps, Gen. A. E. Burnside, with the Army of the Potomac on but acted under the immediate orders of Grant, until the 24th, when it became f the Army of the Potomac.

Strength of the army, including the Ninth 0 April, was 118,769 officers and men, 5 guns. The army was commanded by George G. Meade. Formed in battle line, 10 miles deep, with one-third in reserve, it covered a front of 21 miles. Its train of wagons was 65 miles long. The assigned strength of this army was to attack the Army of Northern Virginia, and by constant hammering it to take Richmond. The army of Northern Virginia, commanded by Gen. R. E. Lee, is composed of the First, Second and Third Infantry corps, commanded by Gens. J. E. Johnston, R. S. Ewell and A. P. Hill. A corps of two divisions (Wade Hampton and Fitzhugh Lee's) was commanded by E. B. Stuart. The most reliable estimates of Lee's strength, present for duty, on 1 May 1864, are 48,700 infantry, 4,854 artillery and 1,999 cavalry, an aggregate of 61,953 men, with 224 guns. On 1 May the Army of the Potomac was encamped in the vicinity of Culpeper Court House, between the Rapidan and the Rappahannock, and the Third and Second corps on the railroad from Manassas Junction to the Rappahannock. Lee's army was south of the Rapidan, Ewell's corps at Mine Run and A. P. Hill's on Ewell's flank near the Rapidan. Longstreet's corps was at Gordonsville. Stuart's cavalry lay behind the lower Rappahannock. Lee's headquarters were near Orange Court House, 70 miles from Richmond.

The Army of the Potomac being the first objective, it was determined to cross the Rapidan, turn north and compel him to fall back toward the Rapidan and come out of his intrenchments to battle on open ground. The principal objection to this movement was the difficulty presented by the Wilderness, a forest of undense growth, with an almost impenetrable undergrowth, where infantry could not move with great difficulty and where cavalry would be of little use. It was thought that this difficulty by moving at night, crossing the Rapidan and getting through the Wilderness before Lee could discover the movement would be met by moving on the Orange turnpike and Orange plankroad. These two roads run from Orange Court House down the Rapidan to Fredericksburg. They follow the direction of the river and are almost parallel to each other; the turnpike nearest the Rapidan and the plank road a short distance from it. Grant's proposed route lay directly between these two roads along the western border of the Wilderness. The movement began on the night of 3 May. Hancock's Second corps, followed by Gregg's cavalry division, crossed the Rapidan at Ely's Ford and moved to Chancellorsville, where the entire corps with its train arrived by noon of the 4th. Warren's corps, preceded by Wilson's cavalry,

crossed the river at Germanna Ford and marched to Wilderness Tavern, at the intersection of the Germanna road by the Orange turnpike. It reached its position by 2 P.M. of the 4th.

Wilson's cavalry was thrown forward to Parker's Store on the Orange plankroad. Sedgwick's Sixth corps followed Warren's across the Germanna Ford and halted a short distance beyond it. The crossing of the river was very gratifying to Grant who regarded it as a great success, and it removed from his mind the most serious apprehension he had entertained "that of crossing the river in the face of an active, large, well-appointed and ably commanded army, and how so large a train was to be carried through a hostile country and protected." At noon of the 4th Grant knew that Lee was aware of his movement, upon which he sent a dispatch to Burnside to make a forced march from beyond the Rappahannock to Germanna Ford, and by the morning of the 5th his advance was crossing the Rapidan. The orders for the 5th were for Sheridan, with two divisions of cavalry, to move against the Confederate cavalry, near Hamilton's Crossing, and at 5 A.M. Wilson's cavalry division was to move to Craig's Meeting House and reconnoitre the Orange pike and plankroads and other roads on his right and left. Hancock's Second corps was to march from Chancellorsville to Shady Grove Church and extend its right toward Parker's Store on the Orange plankroad, to which point Warren's corps was ordered to advance from Wilderness Tavern. Warren, in turn, was to extend his right toward Sedgwick's Sixth corps, which was ordered to Wilderness Tavern.

General Lee interfered with the full execution of these orders. He had been expecting Grant to move on his right and when he saw on the morning of the 4th that the movement was being made, determined to attack him before he could get out of the Wilderness and ordered Ewell to march by the Orange pike and A. P. Hill down the plankroad, and that night Ewell bivouacked within five miles of Wilderness Tavern, and Hill's advance division halted for the night at Mine Run, seven miles from Parker's Store on the plankroad, and about 10 from the intersection of the Brock road. Longstreet moved from near Gordonsville at 4 P.M. Stuart's cavalry was drawn in and ordered to cover the Confederate right. On the morning of the 5th Ewell continued his march on the Orange pike, under instructions to regulate his march with that of A. P. Hill, on the plankroad, and both informed that it was not desired to bring on a general engagement before Longstreet came up, who was under orders to follow Hill on the plankroad. When Ewell was two miles from the Wilderness Tavern, he halted, as he was three or four miles farther advanced than Hill. Warren had discovered that the Confederates, under Ewell, were in force two miles beyond Wilderness Tavern and before 7 A.M. had informed Meade of the fact, who ordered Warren to make an attack with his whole force. Sedgwick was directed to move up by a cross road, attack the enemy and connect with Warren on the turnpike, and a dispatch was sent to Hancock, informing him of what had become known and directing him to halt at Todd's Tavern, until further de-

velopments. Warren had started early in the morning for Parker's Store, on the Orange plankroad, and when near it Crawford's division had been ordered to halt in a good position on high ground, and finding that Wilson's cavalry at Parker's Store needed assistance Crawford threw forward a skirmish line that encountered the flankers of A. P. Hill's corps.

Soon after 8 A.M. Crawford was informed by Warren that Griffin's and Wadsworth's divisions would attack Ewell on the turnpike and he was ordered to join in it with one of his brigades. Between 9 and 10 A.M. Hancock was ordered to move up the Brock road to the Orange plankroad and be prepared to move out that road toward Parker's Store, and about the same hour three brigades of General Getty's division of Sedgwick's corps were ordered from the Wilderness Tavern to the intersection of the Brock road with the Orange plankroad, and directed to move out the latter road and attack the enemy, and, if they could, drive them back beyond Parker's Store. As described by Humphreys, "The Brock road begins on the Orange pike about a mile east of the old Wilderness Tavern, and runs in a southeast direction to Spotsylvania Court House, intersecting the Germanna plank, the Orange plank, the Furnace, the Catharpin and other roads running in a southwest and south direction." Ewell had formed for battle across the Orange pike when about noon Warren opened the attack. Griffin's division advancing on both sides of the pike struck Johnson's division, broke it and drove it back. Rode's division was thrown in on Johnson's right, south of the pike, and supported by Early, who was formed across the pike, the line was re-established. After a severe and bloody fight Griffin was driven back, losing many prisoners and two guns. Wadsworth's division, which had advanced on the left of Griffin, lost direction, exposed its left and was thrown back in confusion. McCandless' brigade of Crawford's division, attempting to unite with Wadsworth's left, was nearly surrounded by Ewell's right and fell back with heavy losses, and Crawford's entire division had to be drawn in.

Thus all the ground gained by Warren was given up and he assumed a new line somewhat in rear, but still in front of Wilderness Tavern, with his right on the Orange pike. He had lost more than 3,000 men. On his right General Wright's division of Sedgwick's corps came up early in the afternoon and with Neill's brigade of Getty's division formed within 300 yards of Ewell's front and repulsed one of his attacks. Soon after this Seymour's brigade of Rickett's division came up on the right of Neill, and about 5 P.M. two brigades of Sedgwick attacked Ewell's left and were repulsed. Meanwhile General Getty, who had arrived at the crossing of the Brock road and the plankroad, had been ordered to attack. Heth's Confederate division was in his front supported by Wilcox's. Hancock, who had been ordered from Todd's Tavern, 10 miles distant, by the Brock road, was instructed to support Getty, drive A. P. Hill beyond Parker's Store and connect with Warren's left. It was 3.15 P.M. when Getty received his order to attack. Meanwhile Hancock's advance had arrived and began intrenching on the Brock road. At 4.15 Getty

advanced to the attack through the thick woods and had gone less than 400 yards beyond the Brock road, when he became hotly engaged with Heth's division. Although Hancock had not completed his dispositions he moved forward to Getty's support and the fight became fierce and deadly at very close quarters and continued until near 8 P.M., when darkness put an end to the fierce contest. Hancock had not gained much ground, but Hill's lines had been broken and his right driven back by two brigades of Barlow's division. While Hancock and Getty were engaged, Wadsworth's division had been ordered in a southeast direction to strike the flank of the Confederates engaging them, but did not become seriously engaged and was halted by darkness, about a half mile from the Brock road.

The Union army had fought in detachments, with no connection of its corps or divisions. Grant said that he had never seen such hard fighting, but prepared to renew it next day, and Hancock, Warren and Sedgwick were ordered to attack at 5 o'clock next morning, and Burnside was ordered to have two divisions in position between Warren and Hancock so as to advance with them. Each corps commander was advised of the instructions given to the others. To note briefly the action of the cavalry on the 5th: Wilson's division, after leaving 500 men at Parker's Store, had proceeded toward Craig's Meeting House on the Catharpin road, and was driven back on that road as far as Todd's Tavern. General Gregg had found nothing at Fredericksburg, but had discovered two brigades of cavalry falling back from Hamilton's Crossing to Lee's right flank, and fell back to Todd's Tavern before 3 P.M. to check the enemy pursuing Wilson and drove them back beyond Corbin's Bridge.

During the night of the 5th Ewell's and Hill's corps strengthened their intrenchments and put artillery in position, and a few minutes before 5 A.M. of the 6th opened the second day's fight by an attack upon the Union right, which was promptly met by the advance of Wright's division of the Sixth corps, which made two vigorous assaults against the Confederate left, which were repulsed with severe loss. Warren made several attacks on Ewell's right which were repulsed. These persistent and unsuccessful attacks were continued until after 10 o'clock, when Sedgwick and Warren were directed to suspend them, to strengthen their intrenchments and throw up new works, in order that a part of their troops might be available for an attacking force to move from the vicinity of Hancock's right, which had been desperately engaged. Hancock had disposed Gibbon's and Barlow's divisions, both under command of General Gibbon, to defend his left flank against an apprehended attack by Longstreet, and at 5 A.M. launched Birney's, Mott's and Getty's divisions, all under General Birney, along the Orange plankroad, Wadsworth's division of Warren's corps at the same time advancing on Birney's right. They fell upon Heth's and Wilcox's divisions of Hill's corps with great fury and after a desperate contest broke them and drove them a mile and a half, through the dense woods, under heavy loss, and back on the trains and artillery, and General Lee's headquarters. Just before Hill's troops gave way the head of

Longstreet's corps, which had marched nearly all night, came upon the field at Parker's Store and was hastened along the plankroad to relieve the divisions of Heth and Wilcox. Kershaw's division was in the lead and began to form on the right of the road.

Humphreys says: "The advance through the forest, underbrush, and swamps more than a mile, in a hot contest, had separated and disordered Hancock's corps, and Birney's left, met in this condition by Kershaw's division, was not only brought to a standstill, but at some points swayed back and forward, until at length Kershaw, himself leading his division, forced Birney's left back as far as his center. Wadsworth's advance had crowded many of Birney's troops to the south side of the plankroad, so that the greater part of his, Birney's, command was on the left of that road. Field's division of Longstreet's corps following close on Kershaw's division, some of it coming on the ground at double-quick, was formed on the Confederate left of the plankroad, and, advancing, at once became hotly engaged with Birney's right and Wadsworth's troops, Gregg's Texans and Benning's Georgians in the lead, bearing the brunt of the fight and losing heavily in killed and wounded. R. H. Anderson's division of Hill's corps, following Field's division, formed on the same part of the line, one portion uniting with Field's troops in the attack, the other portions supporting. It was when Hancock's troops were partially checked by the fresh troops of Longstreet that the necessity of readjusting his formation became imperative. Regiments were separated from their brigades and mixed with others, and the line of battle was very irregular, and commanders were in this way losing the control of their troops. This was about half past six o'clock."

At 9 A.M. Hancock again attacked with the divisions of Birney, Mott, Wadsworth, Stevenson's of Burnside's corps, and three brigades of Gibbon's division and though fighting furiously made no headway, and at 11 o'clock the firing on his front died away. Meanwhile Longstreet had discovered that Hancock's left extended but a short distance from the plankroad and he moved a part of his command to the right to attack Hancock's left and rear, the flank movement to be followed by a general advance of his entire corps. The attack first fell on the left of the advanced line held by Frank's brigade, partly across the Brock road, which was fairly overrun and brushed away; it then struck the left of Mott's division, which in turn was driven back in confusion to the Brock road, and the confusion spread to the troops on the right, and Hancock was compelled to withdraw his entire corps to the Brock road, from which they had advanced in the morning, where they were reformed in two lines behind their intrenchments. Wadsworth, on the right of Hancock, made heroic efforts, but his troops broke, and while striving to rally them he was mortally wounded and died within the Confederate lines next day. When this movement had succeeded Longstreet ordered a general advance, and while riding at the head of column, moving by the flank down the plankroad, when opposite the force that had made the flank movement, which were drawn up parallel with the road, about 60 yards from it,

a volley was fired which killed General Jenkins, commanding the leading brigade of Field's division, and severely wounded General Longstreet. Lee soon came up, postponed the attack to a later hour and extended his line so that its right rested on the unfinished Orange Railroad.

Meanwhile a brigade of the Ninth corps, which had been sent to the left, under Gibbon, swept down in front of Hancock's line from left to right and cleared it of the enemy. In the action of the previous day there had existed an interval between Warren on the turnpike and Hancock on the plankroad, through which Burnside was expected to advance and attack Hill and Longstreet in flank, but in advancing through the woods the enemy was encountered on a wooded crest near the plankroad. An attack was not deemed advisable and Burnside's troops were moved farther to the left. It was not till afternoon and after Hancock's repulse that they became engaged, without accomplishing much, and toward evening they fell back and intrenched. The lull that had followed the successful attack of Longstreet gave Hancock time to re-establish his position now strengthened by fresh troops sent by Meade, and Hancock was directed to renew the fight at 6 P.M. But again Lee anticipated the Union commander, and at 4.15 P.M., having gotten well in hand the troops of Longstreet and Hill, he advanced in force against Hancock's intrenched lines, until he came within 100 yards of the front one, when he opened a severe fire, which was heaviest on Hancock's left, and at the end of half an hour a portion of Mott's division and of a brigade of Birney's gave way in disorder.

The moment this break occurred the Confederates pushed forward and Anderson's brigade of Field's division took possession of that part of the first line of intrenchments and planted their colors on them. Near the point where the line was broken through a fire had, during the afternoon, sprung up in the woods, and at the time of Lee's attack had communicated to the log breastworks on that part of the line. At the critical moment they became a mass of flames, which could not be extinguished and which extended for many hundred yards to the right and left. The heat and smoke were driven by the wind into the faces of the Union troops, preventing them on portions of the line from firing over the parapet, and at some points obliged them to abandon it. It was this condition of affairs that permitted Anderson's brigade to seize a part of the breastworks, from which they were quickly driven by Carroll's brigade, which was near at hand and which rushed upon them at the double-quick. By 5 P.M. Lee's troops had been completely repulsed on Hancock's front, and fell back with heavy losses in killed and wounded.

Just before dark Ewell moved two brigades of Early's division around the right of Sedgwick's corps, held by Ricketts' division, and in co-operation with the rest of Early's division, succeeded in forcing Ricketts back in some confusion, capturing Shaler and Seymour, brigade commanders, and a large number of their men. Wright's division, also, was thrown into some disorder but Wright restored order

and Early drew back and formed a new line in front of his old one.

During the night an entirely new line was taken up by the Sixth corps, its front and right thrown back, a change which was conformed to by the right of the Fifth corps. On the left Sheridan's and Stuart's cavalry had some severe fighting at and near Todd's Tavern in which Sheridan had the advantage. On the morning of the 7th reconnaissances were made of the Confederate position which was found well entrenched; neither commander showed any disposition to renew the fight on that field, and Grant decided to continue the movement by the left flank, and when darkness came the Union columns began their march for Spottsylvania Court House (q.v.). The Union troops engaged numbered about 101,000; the Confederates numbered about 60,000. The Union losses, as officially reported, were 2,246 killed, 12,037 wounded and 3,383 missing, an aggregate of 17,666. The Confederate reports are very incomplete; the most reliable estimate places their entire loss at 7,750.

**WILDERNESS ROUTE**, in American history, a famous emigrant road or trail from the Atlantic seaboard to Ohio through Cumberland Gap. Thousands of emigrants passed over this road to Ohio and Kentucky. The "Wilderness Road" was marked out by Daniel Boone. In 1775 the Transylvania Company, with Col. Richard Henderson as head, engaged Boone to mark out a road from Fort Wautaga, on a branch of the Holston, to the Kentucky River, where the company's newly-purchased lands lay. "This I accepted," wrote Boone, "and undertook to mark out a road in the best passage through the wilderness to Kentucky with such assistance as I thought necessary to employ for such an important undertaking."

**WILDES, Frank**, American naval officer: b. Boston, Mass., 17 June 1843; d. on steamer *China*, off San Francisco, Cal., 6 Feb. 1903. He was graduated from the United States Naval Academy in 1863, served in the West Gulf squadron, and later on the monitor *Chickasaw*. He was promoted master in 1866, became commander in 1880, was in charge of the Portsmouth, N. H., navy yard in 1885-88, and in 1894 was commissioned captain. He commanded the cruiser *Boston* at the Asiatic Station in 1895-98, and served under Dewey at the battle of Manila, 1 May 1898. In 1901 he was advanced to the grade of rear-admiral, was assigned to the Asiatic Station as junior squadron commander, and in 1903 was ordered home on sick-leave, but died on the way.

**WILDFOWL**, in modern usage, water-birds, as ducks, geese and swans, pursued by gunners for sport or for market. American methods of wild fowling will be found where

these birds are described. (See **DUCKS**). An interesting method in Europe, still extensively pursued in some parts of England, at the Fens, is by decoying wild ducks in large trap-ponds. The pond is constructed in a secluded place, well sheltered by trees, and with a plentiful supply of reeds and sedges. From this pond pipes or narrow passages are led, 60 to 80 yards, gradually narrowing toward the termination. Above, the pipe is bridged and covered by a light network, and at its termination it ends in a tunnel net, which is, as a rule, carried out on to the land. Decoy ducks, which come to be fed at the call of the attendants, are used to entice their wild neighbors into the pipe; but the decoy dog is perhaps a more valuable ally of the fowler. This dog is named a "piper." It is of a small breed, and indulges in playful gambols by the side of the pipe, appearing now and then in advance of the fowl, which led by curiosity, swims onward toward the dog, and is thus drawn toward the terminal net. The dog preserves a perfect silence during its manœuvres. Devices of the same character are used in the Orient, especially in Japan. Another Old World method is by employing the stalking horse, still used in some parts of England; the body of the horse—which requires special training for its work—being used to conceal the sportsman from the game. Consult Sanford and Van Dyke, 'Water Fowl,' American Sportsman's Library (New York 1903); Grinnell, 'American Duck-shooting' (New York 1901); Elliot, 'The Wild Fowl of the United States, Etc.' (New York 1898); Mayer, 'Sport with Rod and Gun' (New York 1892); Aflalo, 'Sport in Europe' (London 1901); Hornaday, W. T., 'Our Vanishing Wild Life' (New York 1913); the files of *Outing*, and 'Bulletins' of the United States Bureau of Biological Survey (Washington, D. C.)

**WILES, Irving Ramsay**, American artist: b. Utica, N. Y., 8 April 1861. He was the son of Lemuel L. Wiles, also an artist and director of fine arts at Ingham University, Le Roy, N. Y. He studied under his father and at the Art Students League, New York, and under Carolus-Durand in Paris in 1882-84. He afterward established himself in New York and specialized in the painting of figures and portraits. His fine conception of line and coloring and his strong and sympathetic characterizations have gained him a high place among American artists. He was elected to the National Academy in 1897. He received gold medals at the expositions at Buffalo (1901); Saint Louis (1904); Buenos Aires (1910); and at San Francisco (1915); and was awarded the Proctor portrait prize at the National Academy of Design. Among his paintings are 'Golden Dreams' (Saint Louis Museum), 'Shelter Island, Summer' (Metropolitan Museum, New York); 'The Student' (Corcoran Art Gallery, Washington); 'Russian Tea' (National Gallery, Washington); 'Julia Marlowe' portrait (1903); 'Mrs. Gilbert,' portrait (1904); 'Lemuel Maynard Wiles,' portrait (Metropolitan Museum, 1904); 'George A. Hearn,' portrait (Metropolitan Museum, 1914), etc.

**WILEY, Harvey Washington**, American chemist: b. Kent, Ind., 18 Oct. 1844. He was

graduated from Hanover College in 1867; from the Indiana Medical College in 1872; from Harvard in 1873, and in 1878-79 studied abroad, chiefly at the University of Berlin. He was professor of chemistry at Purdue University in 1874-83, and in 1881-83 was also State chemist of Indiana. In 1883 he became chief chemist of the United States Department of Agriculture, occupying also the position of professor of agricultural chemistry at the graduate school of Columbia University from 1895. He was secretary of the Association of Official Agricultural Chemists in 1889; was president of the American Chemical Society in 1893-95, and was sent to Europe several times as the leading American scientist on the chemistry of foods. He made a specialty of sugar and glucose investigations and was interested in the prevention of food adulteration. In this work he was so active, and wrote so much against the use of artificial "preservatives" in foods, that he gradually antagonized the leading food companies of the country, and through political pressure was removed from the Department of Agriculture. He is deserving of high commendation for his long fight to help keep pure the food of the nation. He has published 'Songs of Agricultural Chemists' (1892); 'Principles and Practices of Agricultural Chemistry' (3 vols., 1894-97); 'Foods and Their Adulterations' (1911); 'The Lure of the Land' (1915), and the 'Bulletins' of the United States Department of Agriculture, etc.

**WILEY UNIVERSITY**, an institution for the education of the colored race, located in Marshall, Tex. It was founded in 1873 by the Freedmen's Aid and Southern Educational Society of the Methodist Episcopal Church, by which it is now chiefly supported. It is open to both men and women. It has elementary, secondary and collegiate departments, and normal, commercial and industrial courses. The Collegiate Department confers the degrees of A.B. and B.L. Industrial work and instruction is given in carpentry, bricklaying, printing, sewing and cooking. The grounds and buildings in 1909 were valued at \$60,000; a building for general purposes was erected in 1900-01. The income in 1917 amounted to \$28,000; the library contained 6,000 volumes; the students numbered 400, and the faculty 26.

**WILFRID, or WILFRITH, Saint**, Anglo-Saxon prelate: b. about 634; d. Oundle, Northamptonshire, 709. He studied at Lindisfarne, became a monk, and in 653 accompanied Benedict Biscop to Rome in order to obtain an authoritative answer to the question of the proper time for celebrating Easter. On his return he obtained from Alchfrid, king of Northumbria, a grant of land and a monastery at Ripon, and here he was ordained priest in 664. In this same year he took a leading part in the conference at Whitby, where he persuaded the king to decree that, in the celebration of Easter, the Roman usage should be substituted for that of the Scottish Church, which had hitherto prevailed in Northumbria. At this time also the king appointed him archbishop of York, but having gone to France to be consecrated by a bishop holding orthodox views on the Easter question, he found on his

return that his see was occupied by one of the opposite party, and he did not get possession till 669. Becoming obnoxious to King Egfrid (who had succeeded Alchfrid in 670), the king, to reduce his influence, divided his diocese into three, and when Wilfrid opposed this proceeding, deprived him of his see altogether (678). Wilfrid thereupon set out for Rome to obtain from the Pope a reversal of the king's act of deposition. Having been driven by a storm on the coast of Friesland, he preached to the people (who had no difficulty in understanding the Anglo-Saxon) with such effect that all the princes and many thousands of the people offered themselves for baptism. Having reached Rome he easily obtained from the Pope the desired decision, but during the reign of Egfrid remained under persecution or in exile; in 687, however, Aldfrid, who had succeeded Edfrid, reinstated him. But Aldfrid also in course of time was offended by his devotion to Rome, and Wilfrid was again deposed in 691. He then made another journey to Rome, and did not return till 705. Consult Eddis, 'Vita Wilfridi,' in 'Historians of York' (Vol. I, 'Rolls Series'); Bright, 'Early English Church History' (3d ed., 1897); Hunt, 'The English Church from its Foundation to the Norman Conquest' (1899).

**WILGUS, William John**, American railroad engineer: b. Buffalo, N. Y., 20 Nov. 1865. He studied civil engineering and entered railroad service in 1885; and was later division engineer of construction on the Minnesota and Northwestern Railroad. He was in charge of the construction of the Chicago Union Transfer Railroad in 1890-93; and in 1893-1907 he was with the New York Central Railroad. He was chief engineer of construction with that railroad in 1899-1903; and later, as vice-president in charge of construction on the New York Central, he superintended the electrification of the lines within a certain radius of New York. He was chairman of the board of engineers constructing the tunnel under the Detroit River. Since 1908 he has been established as a consulting engineer. He was appointed major in the Engineering Reserve Corps of the United States in 1917, and was later colonel in the Railway Transportation Corps with the American Expeditionary Force in France. He was awarded the Rowland prize of the American Society of Civil Engineers in 1909 and the Telford medal of the Institute of Civil Engineers, London, in 1911. He has published 'Physical Valuation of the Railroads' (1913).

**WILHELM MEISTER**, Goethe's greatest novel, consists of 'Wilhelm Meister's Apprenticeship,' published in 1796, and 'Wilhelm Meister's Travels or the Renunciants,' published in final form in 1829. Both parts of the novel deal with the adventures of a young man and the development of his character, each part, however, being conceived from a different point of view. In the 'Apprenticeship' Wilhelm Meister, the son of a well-to-do merchant, decides to join a band of strolling actors, both from personal enthusiasm for their profession and for the noble purpose of raising the German stage to a higher level. But he realizes, after some time, that he is not a born

actor; the company to which he belongs can not keep up the high standard which it had reached in the presentation of Shakespeare's 'Hamlet' (book 5), and makes the stage a place of cheap amusement instead of a place of education; the life of the actors is of an indifferent, drifting nature, depending on the opportunities of the moment. Wilhelm withdraws from the stage and feels more at home with a certain secret society—The Society of the Tower—whose members as a rule belong to the nobility. Real culture and superior skill in worldly matters can be found among them. The high goal which they pursue in the education of man is to develop and to reconcile with each other all the qualities with which the individual is endowed by nature. The common problem which all men have to solve in the course of their lives is the reconciliation of the moral and the sensual, the ideal and the real, while art and perhaps religion are considered the means for attaining such a complete, harmonious personality. Man is to make himself a work of art which, independent of its surroundings, has its object exclusively in itself. Against this inspiring conception of man by which Wilhelm is attracted and which his fiancée Natalie and to some extent also her aunt represent (Cf. 'Confessions of a Fair Saint,' book VI), stand out the pathetic figures of Mignon and the harper, who are doomed to a tragic end. Characteristic features of Germany in the 18th century are the separation of classes into nobles and commoners, the conception of the theatre as a place of education, and the tendency to form secret societies. The construction of the 'Travels' is decidedly loose. Wilhelm himself no longer plays so prominent a part; reflections and maxims, descriptions of conditions and institutions take up a great deal of space, and a number of short stories but vaguely connected with the main story are inserted at different places. The whole is conceived in a new spirit, the spirit of renunciation, the power of which every individual must experience in the course of his life and without which mutually beneficial relations with our fellowmen cannot be established. Accordingly a new standard is set up for the individual and for society. Above all, the individual is to be made a useful member of society, and to this end it is necessary that he should confine his best efforts to one definite activity; Wilhelm chooses surgery for his speciality. The separation of classes, already disregarded at the end of the 'Apprenticeship,' where marriages between nobles and commoners are contracted, is set aside for democratic ideas in the 'Travels' where noblemen in leading positions consider themselves no better than their fellow-workers. The feeling between men has become wider and freer, and so has the feeling between countries. While, in the first part of the novel, emigration to America is rejected, the second part pronounces both emigrating and staying at home equally good, indeed the chief characters—among them Wilhelm—make up their minds to go to America. For good men are at home anywhere where they are useful. A world-society is hoped for which will inform its members about all parts of the world and foster in them a "world-piety" which respects all

forms of religion and government serving mankind while fulfilling their special tasks. The individual, æsthetic man of the 18th century is replaced by the social, practical man of the 19th century; the ideal of the harmony of the individual is eclipsed by the ideal of the harmony of the world. We see the author of 'Wilhelm Meister' like the colossal mythical statue of Apollo at Rhodes standing as it were on the shores of two centuries. Consult edition of Goethe's works in 'Deutsche National-Literatur' (Vols. XV-XVI, 1882-98); 'Wilhelm Meister's theatralische Sendung' (1911); English translations in 'Everyman's Library,' by Carlyle, and in 'Bohn's Libraries,' Bielschowsky, 'Goethe' (Vol. II, 26th edition, pp. 128-183, 513-568); Creizenach, introductions and notes in 'Goethe's Samtliche Werke, Jubiläums-Ausgabe' (Vols. XVII-XX); EWALD EISERHARDT.

**WILHELM TELL.** Schiller's most popular play, if not his best, is 'William Tell,' of which more copies have been sold than of any other German work of literature. During the years 1899 to 1905 a yearly average of 232 stage performances in German lands was maintained, a record equalled by no other German drama. Many critics condemn its structure, others find Tell's slaying of the tyrant Gessler from ambush morally indefensible; but it has become the national poem of the Swiss people. Read and seen on the stage in Germany's dark days it inspired the revolt against the despotism of the great Napoleon, and again in 1848 and later in 1870 its powerful influence was felt and the Rütli oath became the motto of the new empire. On the 100th anniversary of Schiller's birth in 1859 the 'Urkantone' dedicated the immense Mythenstein near the Rütli "To Schiller, Tell's Singer."

Although every child knows the story of Tell's appleshot, it is not Tell but the Swiss people who are the heroes of the drama, or more exactly the three forest cantons Schwyz, Uri and Unterwalden, who by their historical defeat of the forces of the duke of Austria at Morgarten in 1315 and by later victories made themselves independent of the House of Habsburg while remaining in the empire down to the Thirty Years' War. Still, the drama is built about the Tell legend, for history knows no Tell, nor any tyrannical Gessler, nor was there any revolt against Kaiser Albrecht, as in the drama, which follows the chronicle of Ægidius Tschudi (1505-72). The legend, itself, most probably came we know not how, from the Dane Saxo Grammaticus, who wrote in the 12th century, but long before Goethe's visit to the Forest Cantons in 1797, it had been accepted by the Swiss as fact. Goethe had wished to treat the subject in an epic, but resigned it to Schiller for dramatic treatment, helping him with all his data and knowledge of Swiss customs, topography and local color, for Schiller never saw Switzerland. It was finished and first produced in March 1804, and rapidly made its way over delighted Germany, but was not tolerated in Vienna till 1827.

In their revolt against Habsburg tyranny, representatives of the three original cantons met on the Rütli and swore their "desire to be a united people of brothers, to be separated

in no trial and danger; to be free as their fathers were; to suffer death rather than live in servitude; to trust in God on high and not to fear the power of men." Hence Schiller carried three parallel plots, of which Tell, the yeomanry and the nobles were the protagonists, but all blend into one compact whole, leading from a common revolt against tyranny to common success.

The noble blank verse, the occasional lyrics and the striking scenery conspire to make a drama of irresistible charm, such that amateur actors give the play twice a week during the summer at Altorf to never-diminishing audiences.

Editions: Schiller's 'Werke,' (Goedeke,) etc., 1868-76 (Vol. XIV); 'Säkular-ausgabe' (Vol. VII); American school editions: E. C. Roedder, 1905; Arthur H. Palmer, 1915, and a dozen others. Consult Bultaupt, Heinrich, 'Dramaturgie des Schauspiels' (Vol. I); Kuenen, E., 'Schiller's Wilhelm Tell, erläutert und gewürdigt.' There is an English translation by E. B. Lytton, 1844, and nearly 20 others.

CARL E. EGGERT.

**WILHELMINA I**, wîl-hël-mé'nä (Wilhelmina Helene Pauline Marie), queen of the Netherlands: b. The Hague, 31 Aug. 1880. She is the daughter of King William III of the Netherlands by his second wife, Emma of Waldeck. She became queen on the death of her father in 1890, but as she had not attained her majority her mother ruled as queen-regent; Wilhelmina meanwhile was carefully educated under the best tutors. Shortly after her 18th birthday, on 6 Sept. 1898, she was crowned queen at Amsterdam. Her charming personality and strength of character have made her very popular with her people; she has also been strongly influenced by her mother, who is equally well loved by the people. In February 1901 she was married to Henry Frederick, Duke of Mecklenburg-Schwerin; and 30 April 1909 she became the mother of Juliana, Duchess of Mecklenburg.

**WILHELMSHAVEN**, wîl'helms-hä-fën, Germany, town and naval station, on the northern coast of the duchy of Oldenburg, at the west entrance of the Bay of Jade, 40 miles northwest of Bremen, with which it is connected by rail. In 1853 the land was bought from Oldenburg by Prussia, and the town laid out in 1856; it was first used as a naval station in the Franco-Prussian War, and since then has been made a fortress of the first rank. The harbor and fortifications were built at great cost, as the ground is soft and marshy and without natural advantages. The harbor basin, which is artificially constructed and walled with granite, is connected with the bay by a canal and contains three large dry docks; it is defended by forts of immense strength and provided with a torpedo station. The naval workshops were located here; it was one of the most important naval stores of the German empire in the World War. There is also a commercial harbor connected with the naval harbor, but the town has not attained commercial importance. Pop. about 36,000.

**WILIBROD**, wîl'î-brôrd, or **WILLIBROD**, Saint, English missionary, called the Apostle of the Friesians: b. Northumbria,

about 657; d. about 738. He was brought up in Saint Wilfred's monastery at Ripon, spent 13 years in Ireland, and at 33, with several associates, embarked as a missionary for Friesland, where he was warmly welcomed by the Frisian prince, Pepin. Wilibrord made two visits to Rome (692 and 695), and on the latter occasion was made bishop by Pope Sergius over all the converted Friesians. In that part of Friesland under the rule of the Franks, he founded many Christian churches, some of which were destroyed a few years later in consequence of the successes of the pagan Friesians. He was buried in the monastery of Echternach, near Treves, and is commemorated in the Roman Catholic Church on 7 November.

**WILKES**, wîlks, Charles, American naval officer and explorer: b. New York, 1798; d. Washington, 8 Feb. 1877. He entered the navy as a midshipman in 1818, served on the Mediterranean Station in 1819-20, in the Pacific 1821-23 and was then selected for separate command. In 1826 he was promoted lieutenant, and in 1830 was appointed to take charge of the government charts and instruments. In 1838 he was put in command of an expedition for exploring and surveying the Southern seas, the first scientific expedition ever fitted out by the United States government. During the next five years the expedition visited Madeira, Rio de Janeiro, Tierra del Fuego, Chile, Peru, the Paumotu group, Tahiti, Tutuila and the Samoan group, New South Wales, the Antarctic regions, New Zealand, the Fiji group, the Sandwich (Hawaiian) Islands, the Columbia River, Willamette Valley, the coast of California, the Philippine Islands, Sulu Archipelago, Saint Helena, Singapore and the Polynesian Islands. The results of the expedition were published in 19 volumes, those on 'Hydrography' and 'Meteorology' being written by Wilkes himself, who also wrote the 'Narrative of the United States Exploring Expedition' (1845). Wilkes claimed to have discovered an Antarctic continent, but the claim was long disputed. Shackleton's recent discoveries tend to prove the accuracy of Wilkes' announcement. In 1843 he was made commander, in 1855 a captain, and at the beginning of the Civil War in 1861 was placed in command of the *San Jacinto*, in which he went to the West Indies in search of the Confederate vessel *Sumter*. On 8 November of that year he took the Confederate commissioners Mason and Slidell from the British mail steamer *Trent*. (See TRENT AFFAIR, THE). In 1862 Wilkes was in command of the Potomac flotilla and afterward of the flying squadron that operated against blockade-runners. In July 1862 he was promoted commodore, in 1864 was placed on the retired list, and thereon in July 1866 became rear-admiral. Besides those above mentioned his publications are 'Western America, Including California and Oregon' (1849); and 'The Theory of the Wind' (1855).

**WILKES**, John, English politician: b. London, 1727; d. December 1797. He was the son of a wealthy distiller and was educated at the University of Leyden. In 1757 he was returned to Parliament as member for Aylesbury and in 1762 attained considerable reputation by the publication of a paper entitled the *North Briton*, in which the administration of Lord

Bute was severely attacked. These papers hastened the resignation of Lord Bute, April 1763, and the same month the *North Briton* commented on the king's speech in such caustic terms that a prosecution was determined upon. Wilkes, among others, was apprehended; but he asserted the illegality of the warrant and refusing to answer interrogatories was committed to the Tower. Some days after, he was brought by writ of habeas corpus before the court and ordered discharged on the ground that his privilege as a member of Parliament had been violated. On the next meeting of Parliament, however, a special law was passed to sanction Wilkes' prosecution, and in January 1764 he was expelled from the House of Commons. A second charge was also brought against him for printing an obscene poem, entitled an 'Essay on Women,' and he was found guilty of blasphemy as well as libel. As he had by this time withdrawn to France and did not appear to receive sentence, he was outlawed. He made vain attempts to procure the reversal of his outlawry, but trusting to his popularity ventured to return on a change of ministry (1768). He was elected to Parliament for Middlesex, but before he could take his seat was committed to prison to fulfil the sentences previously passed upon him, and not long after was expelled from the House for an alleged libel upon the Secretary of State and Secretary at War. Three times after this he was re-elected within a few months, but the House of Commons persisted in keeping him out, and after the third election the other candidate, although he had got but a small minority of the votes, was declared duly returned. In 1770 he was released from his imprisonment. He was now more than ever the idol of the people. He was elected alderman of London, sheriff of Middlesex, and finally mayor (1774). In 1774 he was again elected to Parliament for Middlesex and allowed to take his seat, which he held till 1790. His last triumph was obtained in 1782, when the resolutions respecting the disputed Middlesex elections were ordered to be expunged from the journal of the House of Commons. From the year 1779 he was chamberlain of the city of London. Wilkes, as a writer and speaker, did not reach beyond mediocrity. His private character was very licentious, but he possessed elegant manners, fine taste, ready wit and pleasing conversation. His 'Letters and Speeches' were published by himself in 1786; and much light is thrown upon his conduct by the 'Letters from the Year 1774 to the Year 1796 to His Daughter' (1894). His correspondence was also published (1805), with a memoir by Almon. Consult Fitzgerald, 'The Life and Times of John Wilkes, M.P.' (1888).

**WILKES-BARRE**, Pa., county-seat of Luzerne County and regarded by many as the most beautiful city in the State, on the north branch of the Susquehanna River, and on the Central Railroad of New Jersey, the Wilkes-Barre and Eastern, the Delaware and Hudson, the Wilkes-Barre and Hazleton, the Delaware, Lackawanna and Western, the Lehigh Valley, the Lackawanna and Wyoming Valley and the Pennsylvania railroads, 110 miles northwest of Philadelphia and 110 miles west of New York City. It was first settled in 1769 by New England people, mainly from Connecticut, under

the auspices of The Susquehanna Company, and was named in honor of John Wilkes and Isaac Barré (qq.v.), members of the British Parliament. During the Revolutionary War the settlers were, with few exceptions, loyal to the patriot cause. July 3, 1778, the male inhabitants of Wyoming Valley, who were assembled at Forty Fort to repel an invading foe, were attacked near the fort (on Abraham's Plains, some seven miles from Wilkes-Barre) by a battalion of British Rangers with their Indian allies, and were badly defeated. The Wyoming Monument, erected near the field of battle, commemorates the valor of the Americans who fought on this bloody field. Following the surrender of Forty Fort, on 4 July 1778, Wilkes-Barre was almost wholly destroyed by the enemy. Wilkes-Barre was, in the period of 1769 to 1784, the centre of the controversy between Connecticut and Pennsylvania, each State claiming territorial jurisdiction over the Wyoming region (see PENNSYLVANIA, *History*) and was the scene of several conflicts during that controversy, being almost entirely destroyed by fire at one time in 1784. It was gradually rebuilt and was incorporated as a borough in 1806; its growth has been rapid since the Civil War; and in 1871 it was incorporated as a city. It is situated near the centre of Wyoming Valley, in the midst of picturesque scenery. Wilkes-Barre is the birthplace of the anthracite coal-mining industry. It was here the discovery was made that there existed on this continent such a mineral as anthracite (or "stone coal" as it was early called). Here anthracite was first used for fires in naileries and blacksmiths' shops; and was thus used for upward of 20 years before the existence of anthracite in any part of Pennsylvania save Wyoming Valley was known. Here anthracite first came into use as a fuel for domestic purposes. Wilkes-Barre lies in the seventh anthracite mining district of Pennsylvania and from the 37 mines and washeries in operation in the district there are produced annually about 5,000,000 tons of coal. The manufacturing and mechanical industries of the city are large; the census for 1914 reported over 400 establishments, with a combined invested capital of \$19,000,000 and a gross production of nearly \$17,000,000. Among these, silk and lace mills, axle-works, foundries and machine shops and wire-rope works are the most important. The city also contains breweries, manufactories of cotton goods and the Lehigh Valley Railroad shops. There are three national banks and six savings banks and trust companies working under State charters. The city is well built and has a public square containing four acres and a park ("The River Common") containing 35 acres along the river front. In the vicinity of the city are the Wyoming Monument, already mentioned, the old Forty Fort Church, Harvey's Lake (the largest lake in Pennsylvania) and other points of historic interest. The notable public buildings are the city hall, courthouse, jail, post office, armory and Memorial Hall. The city has a number of charitable institutions, including two hospitals - one the City Hospital and the other Mercy Hospital (under the management of the Roman Catholics); a Home for Friendless Children and a Home for Homeless Women. It has 20 public school buildings, including the

high school building erected in 1890, in which, in addition to the usual studies, instruction in manual training is given. It has also six Roman Catholic parish schools and is the seat of Harry Hillman Academy (for boys), the Wilkes-Barre Institute (for girls), the Wilkes-Barre Business College, the New Century School of Correspondence and two Roman Catholic academies for girls—Saint Mary's, connected with Saint Mary's Convent, and Saint Ann's, connected with Mallinckrodt Convent. There are two large public libraries—The Osterhout Free Library (having reference and circulating departments), and the reference library of the Wyoming Historical and Geological Society. In addition, the Law and Library Association, the Young Men's Christian Association and other organizations have library collections. The government of the city is of commission form, the mayor being elected for four years and the four councilmen for two years; the appointing power rests with the mayor and commission. Pop. 75,000. But, elbowing the city on all its boundaries are boroughs and hamlets, so that within a radius of nine miles from the centre of Wilkes-Barre there is a population of approximately 200,000.

**WILKIE**, wil'ki, SIR David, Scottish painter: b. Cults, Fifeshire, 18 Nov. 1785; d. at sea, off Gibraltar, 1 June 1841. In 1799 he entered the Trustees' Academy, Edinburgh, where he studied for several years. In 1804 he returned home and painted 'Pitless Fair,' the first of that class of works for which he became famous. In 1805 he went to London, taking with him the 'Village Recruit,' which at length found a purchaser for £6. The Earl of Mansfield purchased his 'Village Politicians,' which at the Royal Academy (1806) excited universal admiration. It was succeeded by the 'Blind Fiddler' and among the works painted between this period and 1821 may be mentioned the 'Rent Day' (1807); 'Blindman's Buff' (1813); 'Distraint for Rent' (1814); 'The Penny Wedding' (1818); the 'Reading of the Will' (1820); and the 'Chelsea Pensioners,' begun in 1817 and finished in 1821, for the Duke of Wellington. Among the most noted of his later pictures are the 'Entrance of George IV into Holyrood'; the 'Spanish Council of War'; and the 'Maid of Saragossa.' In 1836 William IV created him a knight. In 1840 he made a journey to the East and on the way home was attacked by fever at Malta and died at sea.

**WILKINS**, wil'kinz, Mary Eleanor. See FREEMAN, MARY ELEANOR WILKINS.

**WILKINSBURG**, wil'kinz-bërg, Pa., borough, Allegheny County, on the Pennsylvania Railroad, seven miles east of Pittsburgh. It was formerly called McNairville and Rippeyville and was given its present name in honor of William Wilkins, Secretary of War in 1843-45; it was incorporated as a borough in 1887. Its business interests are identified with those of Pittsburgh and it is almost entirely a residential town; it contains two banks and two newspapers. It is the seat of a home for aged women (Protestant) and of the United Presbyterian Home for the Aged; and there is a high school, established in 1898. Pop. 25,000.

**WILKINSON**, wil'kin-son, Henry Spenser, English author: b. Manchester, England, 1 May 1853. He was educated at Owens College,

Manchester, and at Merton College, Oxford, and in 1880 was called to the bar. He was on the staff of the Manchester *Guardian*, 1883-92, and since 1895 has been on the staff of the London *Morning Post*. His writings include 'Essays Toward the Improvement of the Volunteer Forces' (1886); 'The Brain of an Army' (1890); 'The Great Alternative, a Plea for a National Policy' (1894); 'The Nation's Awakening' (1896); 'British Policy in South Africa' (1899); 'War and Policy' (1900); 'The Nation's Need, Chapters on Education' (edited, 1903), etc.

**WILKINSON**, James, American soldier: b. Benedict, Md., 1757; d. near City of Mexico, 28 Dec. 1825. He studied medicine in Philadelphia and in 1775 enlisted in Washington's army. He became intimate with Benedict Arnold and Aaron Burr, and, having received a captain's commission, joined Arnold's expedition to Canada. He was later appointed to the staff of General Gates, was promoted colonel, and subsequently became deputy adjutant-general of the army of the northern department. In the Saratoga campaign he appropriated as his own the information of the British position and strength which had been secured by Col. John Hardin and after the surrender of Burgoyne was commissioned to bear the news to Congress, carrying with him also the recommendation of Gates that he be appointed brigadier-general. He was 18 days in making the journey and the news was a week old when he delivered his message. Congress refused to grant his promotion at that time, but a few weeks later, through the influence of Gates, he was brevetted brigadier-general and subsequently was appointed secretary of the board of war, of which Gates was also a member. He was deeply implicated in the Conway Cabal (q.v.), which his indiscretion betrayed and was then forced to resign his brevet rank, though retaining his colonelcy. He took no further active share in the war until 1779, when he was appointed clothier-general, an office which he resigned in 1781. He removed to Kentucky in 1784 and in 1786 founded Frankfort. He gained considerable political influence there, intrigued with the Spanish government, with the hope of forming of the Western country a separate republic under the protection of Spain. His reward for this betrayal of his country was to be the exclusive control of commerce on the Mississippi and a yearly pension from the Spanish government. The plot was to be consummated at the convention which met in 1788 for the purpose of forming a constitution for the new State of Kentucky. Wilkinson's influence, however, proved insufficient, and the plot, becoming known to other leaders, fell through. The part of Wilkinson remained a secret, and though he continued to receive his pension from the Spanish government until 1800, he applied in 1791 for service in the army. His treasonable act not being known, he was appointed lieutenant-colonel, served in the Indian wars of the West and was prominent in Anthony Wayne's campaign. He was promoted brigadier-general in 1792, and in 1796 succeeded Wayne in the command of the army. After the acquisition of Louisiana he was appointed in 1805 governor of the Territory of Louisiana and in this position engaged with Aaron Burr (q.v.) in the latter's scheme for founding an empire in Mexico.

In 1806 Wilkinson, perceiving an opportunity to drive a double bargain, betrayed the scheme to the President, and at the same time demanded from the viceroy of Mexico a reward for saving that kingdom to Spain. The assertions of Burr as to Wilkinson's complicity in the plot were generally believed, but at that time no proof of his guilt was obtainable, though he barely escaped indictment on the same charge with Burr in 1807. Inquiry concerning his pension from the Spanish government was made in that year upon a resolution of John Randolph, but he was exonerated. Charges were again made against him in 1810 on the score of complicity with Burr and of receiving pay from the Spanish government, but he was finally acquitted in December 1811, and resumed command in the army. He was promoted major-general during the War of 1812, and commanded the Canada Expedition, but proved incompetent and in 1814 was superseded. He was court-martialed in that year on several serious charges—neglect of duty, conduct unbecoming an officer, drunkenness, etc.—but in 1815 was acquitted and honorably discharged from the army. He then removed to the City of Mexico, where he spent the remainder of his life. He published 'The Aaron Burr Conspiracy Exposed' (1808); and 'Memoirs of My Own Times' (1816). Consult Clark, 'Proofs of the Corruption of Gen. James Wilkinson' (1809); Gayarré, 'Spanish Dominion in Louisiana' (1854); Gilmore, 'Advance-Guard of Western Civilization' (1887); Roosevelt, 'Winning of the West,' Vol. III (1894); Green, 'The Spanish Conspiracy' (1891); McCaleb, 'The Aaron Burr Conspiracy' (1903); and 'Later Intrigues of Wilkinson with the Spaniards' (in 'Amer. Hist. Review,' Vol. XIX, New York 1914).

**WILKINSON, Jemima**, American religious visionary: b. Cumberland, R. I., 1753; d. Jerusalem, Yates County, N. Y., 1 July 1819. She was educated as a Quaker and at 20, after a severe attack of fever, professed that she had been raised from the dead, that her carnal life was ended and that henceforth her body was reanimated by the spirit and power of Christ. She pretended to work miracles, and, though entirely illiterate, induced many intelligent people to become her followers, her attractive person and extraordinary tact and shrewdness aiding her in maintaining the imposture. In 1786, at a meeting of her disciples, it was resolved to found a colony in Yates County, N. Y., in the present town of Torrey. The next year 25 of her followers went to the new purchase and prepared the land for wheat. In 1789 two of the number purchased 14,000 acres of land in that vicinity, to which was afterward added the township of Jerusalem. The same year Jemima and a large number of her followers came, and a house was erected for her. She had taken the name of the "universal friend," and assumed a costume which belonged about equally to either sex, as she asserted that in her spiritual body there was no sex. She was accompanied by two "witnesses," Sarah Richards and Rachael Miller. She exacted from her followers the most complete submission and the most menial services, her influence over them being practically supreme. A farm of 1,000 acres was set apart for her special use

and cultivated freely by her followers. She insisted on the Shaker doctrine of celibacy, and the exercises at her religious meetings resembled those of that sect. She never relinquished her pretensions, but after some years her influence waned, and the latter part of her life was embittered by jealousies and annoyances which she bore with no great fortitude. After her death the sect was entirely broken up. Consult Hudson, 'Jemima Wilkinson, a Preacheress of the 18th Century' (1821); 'Memoir of Jemima Wilkinson' (Bath, N. Y. 1844).

**WILKINSON, Sir John Gardner**, English archaeologist: b. Haxendale, Westmoreland, 5 Oct. 1797; d. Llandovery, Caermarthenshire, 29 Oct. 1875. He was educated at Harrow and Oxford, and after leaving Oxford lived in Egypt 1821-33, during his stay making a thorough study of the ancient monuments of that country as well as of the languages and manners of the modern inhabitants. The most important fruit of his labors was a work entitled 'Manners and Customs of the Ancient Egyptians Derived from a Comparison of the Painting, Sculpture, and Monuments Still Existing, with the Accounts of Ancient Authors' (1837-41), which still remains a standard authority on all that relates to Egyptian art. His later works about Egypt are of a more popular character. Among them are 'Modern Egypt and Thebes' (1833), afterward abridged and published as a 'Handbook for Travelers in Modern Egypt' (1847); 'A Popular Account of the Ancient Egyptians' (1853), and 'The Egyptians under the Pharaohs' (1851), forming a supplement to the previous work. His principal other works are 'Dalmatia and Montenegro' (1848), and 'Color, and the Necessity of a General Diffusion of Taste Among All Classes' (1858). He was knighted in 1839. The collections made by him were given in part to the British Museum, but a considerable proportion of them was presented to Harrow.

**WILKINSON, William Cleaver**, American educator: b. Westford, Vt., 19 Oct. 1831. He was graduated from the University of Rochester in 1857, was ordained in the Baptist ministry in 1859 and in 1859-61 was pastor of the Second Baptist Church, New Haven, Conn. He was professor *ad interim* of modern languages at the University of Rochester in 1863-64, and was engaged in pastoral work at Cincinnati, 1863-66. He was professor of homiletics and pastoral theology at the Rochester Theological Seminary in 1872-81, was engaged in literary work in 1873-92 and has since been professor of poetry and criticism at the University of Chicago. He was counsellor of the Chautauqua Literary and Scientific Circle and has published 'The Dance of Modern Society' (1868); 'A Free Lance in the Field of Life and Letters' (1874); 'The Baptist Principle' (1881); 'Poems' (1883); 'Edwin Arnold as Poetizer and Paganizer' (1885); 'Classic German Course in English' (1887); 'The Epic of Saul' (1891); 'The Epic of Paul' (1898); 'The Epic of Moses' (1903); 'Daniel Webster: a Vindication' (1911); 'Paul and the Revolt Against Him' (1914).

**WILKINSONIANS.** See **RELIGIOUS SECTS**

**WILL.** It has been usual to classify mental phenomena under the three headings of cognition, feeling and will or conation. In the last class are included all those processes in which the mind is regarded as effecting some change in its own states, or in the physical environment by means of bodily movements. These changes may take place in a more or less conscious way: that is, in producing changes by means of inner or outer acts of will, we may be more or less explicitly aware of the nature of the result to be attained and of other possible lines of action. It is an essential characteristic of the states that we name impulses or instincts that they are not deliberative. These processes, however, as expressions of the appetitive or active powers of the mind, are conative in character. Automatic or reflex acts, on the other hand, being brought about without any mediation of consciousness, cannot be regarded as belonging to will at all. In impulse the act is initiated by a feeling of uneasiness or craving which has a tendency to discharge immediately in some movement to relieve this feeling. It is from such immediate and impulsive reactions of consciousness that those more explicit and conscious processes that we call voluntary acts develop. We are not born with the power of performing voluntary acts, but this is a progressive acquirement that presupposes an experience of the results of involuntary acts, and the means of obtaining or avoiding these results. The development of will, in the true sense in which it is an endowment that belongs only to rational beings, as it passes from the stage of impulse and instinct, involves a growing consciousness of the relative value of various ends, and also of the means that may be used for the realization of these ends. The development of will is thus only possible through the development of the mind as a whole. Moreover, it is to be noted that this development implies further the systematic integration and union of the rational and emotional sides of mind with its active or conative aspect. As mind develops, all of its functions become more closely and organically connected.

What has just been said may serve to show the fallacy in the view of the older psychology which regarded will as a distinct faculty, opposed, as if it were a separate department, to feeling and cognition. It was too often forgotten in making this division that these faculties were not each *sui generis*, and that the so-called "faculty" is only an abstraction if thought of as a kind of entity apart from the concrete processes of consciousness. Moreover, the emotional and cognitive states of mind do not exist in separation from the conative aspect, but the latter is necessarily implicated and involved in them. It has been one of the most important achievements of recent psychological analysis to exhibit the presence of will in various intellectual processes, like perception, association and thinking, in the form of the selective activity of attention. The true view then is that cognition, feeling and conation are "moments" or "aspects" of mind that can be distinguished by analysis, but which exist and function concretely only in relation to each other. At the present time, psychologists are not agreed as to whether it is possible to discover by analysis any definite conative process as a structural ele-

ment in conscious life, corresponding to the elementary sensations or feelings. The reality and functional efficiency of the will is not really at stake in this question, however, as has been too hastily assumed by certain representatives of both parties to the dispute. Even if it is found that the processes of will cannot be isolated as separate and distinct states of mind, there will be no ground for denying the real activity of the subject. The truth seems to be that will cannot properly be represented in the form of one particular kind of mental content, just because it is the expression of the attitude of the self toward all mental content.

We have seen that those processes of fully explicit will that we term voluntary acts are always accompanied by a somewhat clear consciousness of the end to be realized and of the relation of means to this end. Moreover, in a fully deliberative act of will, there is also a recognition of various competing possibilities and a conscious selection of one to the exclusion of the others. Instead of allowing an impulse to pass at once into action in accordance with the immediate demands of some single want or uneasiness, in voluntary states consciousness takes control, looking before and after and comparing the consequences of different lines of action. In many cases its efficiency and control are shown by checking or inhibiting the immediate impulse by the thought of some more valuable end with which it conflicts.

How are such volitions to be described psychologically? What actually goes on when a decision is voluntarily made? If we leave out of account the various sensations of muscular strain that accompany volitions, we may say that the essence of the act consists in fixing one alternative and holding it fast before us by means of selective attention. This attention is not passively determined by the greater intensity or immediate attractiveness of one object, but is the result of the fullest activity of the subject, and is at once a psychological fact and a moving force in the external world. As Professor James remarks: "We do not first have a sensation or thought, and then have to add something to it to get a movement. Movement is the natural immediate effect of feeling, irrespective of what the quality of the feeling may be. It is so in reflex action, it is so in emotional expression, it is so in voluntary life."

**The Freedom of the Will.**—The vexed problem of the freedom of the will arises from the fact that there seems to be an antagonism between the demands of our intellect and those of our moral nature. On the one hand, there is the requirement that all phenomena of the inner life, like those of external nature, shall be capable of explanation according to the law of cause and effect. On the other hand, it is maintained that if morality is to have any meaning, the individual must be free and thus responsible for his acts. In favor of determinism, it is argued that the mental life is composed of a series of states or processes that are related to each other causally just as are events in the external world; this is the necessary assumption of psychology and of all the sciences that attempt to explain the mental life. "Whenever determination by necessary laws ceases, there ceases also the possibility of any explanation." Moreover, determinists point out

that the individual is moved to act by certain motives and that these motives are the resultant of certain external influences as modified by his character. This character again is the product of previous acts, either of his own or of his ancestors; so that at any time the act performed is the necessary reaction of the individual in the given circumstances. Furthermore, it is maintained that there is an unbroken line between acts that are performed from instinct or impulse, and where consequently there can be no claim made for freedom, and the most complicated and deliberate acts of will. On the other side, those who contend for freedom argue that we have no right to consider the mind of man as simply a part of nature and subject like it to necessary laws of causation. They urge in support of their position that personality, the principle of intelligence itself, cannot properly be represented as one factor on a level with others, but that it is the centre from which the very conception of law springs, and on another side is the determining ground of all motives and furnishes the standard by which they are evaluated. Appeal is also made to the immediate conviction of freedom that is present in all genuine cases of willing. Further, it is said that it is only on the assumption of freedom that such terms as "responsibility," "duty," "obligation" and "remorse" have any meaning. He who denies freedom, then, declares the experiences denoted by these words to be illusory.

It is impossible to give in the present article a detailed examination of these arguments. A few remarks may, however, be added regarding the general nature of the problem and the lines along which a reconciliation may be effected. In the first place, it is obvious that this controversy is a special phase of the general problem of mechanism (q.v.) and teleology (q.v.). Is everything to be explained according to necessary laws of cause and effect, or is it possible without doing violence to this principle to maintain a determination according to ends? If it is possible for the individual to set before himself the ends of his life, and to work for their realization, he is free in the only sense in which the word has any meaning. If, however, his acts are determined by some force that acts independently of him, he cannot be held responsible. Again, determinism is the only standpoint from which psychology as a natural science can proceed. For this science views the mental life as made up of a series of processes or mental phenomena. Its task, therefore, is to discover how these various elements are linked together according to causal laws. From the very nature of its postulates it is impossible to admit that there is any break in the line of causes and effects; every "state of mind" must be explained by showing that it stands in necessary relations to some other phenomena belonging to the same series. But this is to look at the mind from the outside, as composed of a number of phenomena, or mere occurrences in time. It is, however, possible to describe mind in a way that is truer to the direct experience of life, as a system of conscious functions or acts in which purposes are being realized and ends attained through the self-directed activity of the subject. As soon as this point of view is taken the causal and deterministic position is

left behind, and the only possible assumption that of self-determination or freedom. conclusion we have reached then is that, so as we regard mind from the standpoint of psychology as a science, everything must be explained causally, and that there is no possibility of introducing here the conception of free will. But we have also seen that this standpoint is not final, but that experience can be more adequately interpreted as a process in which the conscious subject realizes ends that he himself sets, and that this view necessarily regards mind as something more than a series of causally determined phenomena.

JAMES E. CREIGH  
*Professor of Logic and Metaphysics, Columbia University.*

**WILL, in law,** is a disposition made by a competent person known as the testator, the form more or less prescribed by law, or the act over which he has the legal power and authority, to take effect at death. Technical term "will" is used to describe a document which disposes of real property, while "testament" is used to describe one that disposes of personal property, "will and testament" including both. Broadly, and by common usage, the term "will" covers both meanings and is accepted as describing a written instrument which disposes of both realty and personalty. A person of legal age, being of sound mind and memory and not under duress, may make a will disposing of whatever interest he has in his property at his death in either real or personal property. All wills to be valid in the United States must be in writing, with the exception of a favored class known as "nuncupative wills" which are oral, unwritten and signed by the testator and witnessed by at least two (or in several of the United States three) persons, who must be in the presence of the testator and of other, and are not beneficiaries under the will. The maker of a will must be 21 years of age in most of the States, but a few allow a person of 18 to thus legally dispose of their property. Oral wills are permitted in the case of soldiers and sailors in actual service, and these "nuncupative" wills are definite statements of the will of the maker with two or more witnesses who shall within a reasonable time thereafter reduce the statement to writing and sign the same. A beneficiary cannot be a witness to a nuncupative will. A will may be altered or amended by the addition of a subsequent will or by the amendment known as a "codicil," which must be made by the testator and witnessed with the same formality as the original will. A will may be revoked by the testator by destroying, canceling, tearing, burning or otherwise

ing it, or by making a new will, which later document invalidates all preceding wills. The destruction of a later will revives a former will if still in existence, which will then have full effect. In some States the subsequent marriage of the testator invalidates a will. The laws of the different States vary as to the provisions for the heirs and next of kin.

A will may be written in any form of language that expresses the intention of the testator. A very common form of beginning a will is: "In the name of God, amen. I, John Smith, being of sound mind," etc. It need not be written in any prescribed form, but must show the intention. It may be written in any sort of writing material or on several pieces of paper if their sense shows them to be connected each to the other. Separate documents may be included in the will if the will speaks of their incorporation in the will as a part of it, and in such a way as to identify the documents. Publication is the act of making known in the presence of witnesses that the instrument executed is the will of the testator. It is not necessary for the witnesses to know the contents of the will, but the fact that it is a will. Publication is not necessary in all States. A will usually names one or more persons who shall carry out the will of the testator. This person is known as the executor or executrix. When no person is named in the will the court appoints such person, who is known as the administrator or administratrix. At the death of the testator the will is placed on file for probate in the Probate or Surrogate Court. A will is construed liberally, the words taken in their plain and usual sense, and the intention of the testator allowed to prevail wherever possible to understand such intention. Effect is given to every part of a will. Rules of construction are valuable only in case the will is contested. Favor is shown in case of contest to natural heirs and next of kin. Conditions may be made, and trust estates created, and whatever interest the testator may have at death may be disposed of by will during his lifetime to take effect at death. When a testator has a large estate it is customary to have his will drawn up by an attorney who is familiar with rules of construction and of evidence. This is not necessary to the validity of a will, which may be written by any one so long as it is properly signed and witnessed.

**WILL-O'-THE-WISP.** See *IGNIS FATUUS*.

**WILLAMETTE**, wil-ä'mët, a river in Oregon which has its rise in Lane County, flows nearly north and enters the Columbia River in Columbia County, in the northwestern part of the State. The total length is about 225 miles. It was originally navigable only for large steamers to Portland (q.v.), 15 miles from its mouth, but the canal around the Willamette Falls permits river traffic 100 miles or more.

**WILLAMETTE UNIVERSITY**, a co-educational institution of higher learning at Salem, Ore. It was founded as an Indian mission school in 1834 and became a school for white children in 1844; while it was established as the present university in 1853. Its school of medicine was organized in 1867 and that of law in 1884. Its other courses include liberal arts,

theology, art and music. It confers the degrees A.B., A.M., B.D., M.D., D.D. and LL.D. In 1918 it had 283 students enrolled, 46 with the colors, and there were 16 instructors. The grounds and buildings are valued at \$350,000, while the endowment is about \$575,000.

**WILLARD, Archibald M.**, American painter and illustrator, son of a Baptist clergyman: b. Bedford, Ohio, 1836; d. Cleveland, Ohio, 11 Oct. 1918. The family settled later at Wellington, where the boy developed a marked interest in sketching, but opportunity for training in artistic lines being wanting, he worked for some years at decorative painting and continued his efforts in sketches and portraits. At the outbreak of the Civil War he enlisted with the 88th Ohio regiment and served as color-bearer. After the war he made battle sketches but at length found his forte in sketches showing humor and intensity of action and emotion. His better known subjects are 'Pluck'; 'The Nursery'; 'The Drummer's Last Yarn'; 'Deacon Jones's Experience'; and 'Pitching the Tune.' His more serious work includes 'Minute Men of the Revolution' and 'Spirit of '76.' The last named was originally entitled 'Yankee Doodle,' and was produced for Centennial year. The models used were Hugh Mosher, a local fifer, and his father, and Harry, son of Gen. J. W. Devereux, as the drummers. The picture was received with popular enthusiasm and exhibited at the Philadelphia Centennial and the larger cities of the United States. It was finally purchased and presented by General Devereux to his native town, Marblehead, Mass., where it hangs in Abbott Hall. The artist lived for some years in New York but passed his earlier and later years in Cleveland.

**WILLARD, Ashton Rollins**, American art critic: b. Montpelier, Vt., 14 April 1858. He was graduated from Dartmouth in 1879, removed to Boston in 1887 and has since spent much time in Europe. In 1902 was made chevalier of the Order of the Crown of Italy. His writings include 'Life and Work of Painter Domenico Morelli' (1895); 'History of Modern Italian Art' (1898); 'Land of the Latins' (1902).

**WILLARD, Edward S.**, English actor: b. Brighton, Sussex, 1853; d. 9 Nov. 1915. His first appearance on the stage was made at Weymouth in 1869, but his London début was not made until 1881. He became manager of the Shaftesbury Theatre in 1889 and in 1890 came to the United States, where he played successfully for three years. He leased the Comedy and Garrick Theatres in London in 1894 and later made several tours of the United States, playing various leading parts under his own management.

**WILLARD, Emma Hart**, American educator: b. Berlin, Conn., 23 Feb. 1787; d. Troy, N. Y., 15 April 1870. She began her career as a teacher in 1803, subsequently became principal of a girls' academy at Middlebury, Vt., and in 1809 was married to Dr. John Willard. She opened at her home in Middlebury, Vt., in 1814, a boarding school for girls in which she introduced various improvements in methods of instruction and also taught subjects hitherto not included in the curriculum of girls' schools.

Desiring a broader field for the development of her ideas of education she addressed to the New York legislature in 1819 a treatise entitled 'A Plan for Improving Female Education.' It was an able exposition of excellent ideas and found favor with Gov. John Clinton, resulting in the establishment in that year of a seminary for girls at Waterford, N. Y., which was incorporated and was partially supported by the State. She removed to Troy in 1823, where she was presented by the city with a suitable building for her school, henceforth known as the Troy Female Seminary. After the death of her husband in 1825 she conducted the business management of the school in addition to her other work until 1838, when she resigned her duties into the hands of her son. She traveled in Europe in 1830, assisted in founding a school for girls in Athens, Greece, and afterward published 'Journal and Letters from France and Great Britain' (1833), the proceeds of which she presented to the school. She was married to Dr. Christopher C. Yates in 1838, but in 1843 she secured a divorce from him and resumed her former name. She traveled 8,000 miles through the Southern States in 1846 engaged in lecturing before conventions of teachers, and in 1854 was present at the World's Educational Convention in London. Mrs. Willard is one of the most prominent figures in the history for higher education for women in the United States. She was not only an advocate of advancement but a practical worker for it, and brought to her task great earnestness of purpose, coupled with high abilities and executive capacity. Her school-books were widely used and were translated into European and Asiatic languages. They include 'The Woodbridge and Willard Geographies and Atlases' (1823); 'History of the United States' (1828); 'Treatise on the Circulation of the Blood' (1846); 'Last Leaves of American History' (1849); 'Astronomy' (1853); 'Morals for the Young' (1857), etc. She also wrote some excellent verse, which includes the famous 'Rocked in the Cradle of the Deep.' A statue was unveiled to her memory at Troy in 1895. Consult Lord, John, 'Life of Emma Willard' (1874).

**WILLARD, Frances Elizabeth**, American educator and temperance reformer: b. Churchville, N. Y., 28 Sept. 1839; d. New York, 18 Feb. 1898. She was graduated from the Northwestern Female College, Evanston, Ill., in 1859, engaged in teaching, was appointed professor of esthetics in the Northwestern University in 1869, and became dean of the Women's College of that institution in 1871. In 1874 she resigned this position, was elected secretary of the Woman's Christian Temperance Union in that year, and in 1879 she became its president, an office she held until her death. In her management of the association she displayed great executive ability and a remarkable genius for organization. She founded in 1883 the World's Christian Temperance Union, and in 1888 became its president. She declared herself in favor of woman's suffrage in 1876, and thereafter lectured occasionally upon the subject, deeming the ballot a protection to women from the miseries caused by drink. In 1892 she visited England, where she was the guest of Lady Henry Somerset, the temperance re-

former, and while there addressed a mass meeting at Exeter Hall, said to have been one of the largest assemblages ever held there. She devoted her life to a cause, and won the admiration and love of a vast number of people, even those who did not agree with many of her views. In all the long list of reformers who have sought to rid the world of the evils of the liquor traffic there is no name that stands higher than that of Frances E. Willard. In her work Miss Willard displayed an untiring energy, and for 10 years she averaged a meeting a day, meanwhile continuing her literary labors. She was editor of the *Chicago Post and Mail* for a short time after 1878, and from 1892-98 editor-in-chief of the *Union Signal*, the official organ of the temperance movement. Her publications include 'Nineteen Beautiful Years' (1868); 'Woman and Temperance' (1883); 'Glimpses of Fifty Years' (1889); 'A Great Mother' (1894), etc. She also edited with Mary A. Livermore, 'A Woman of the Century' (1893).

**WILLARD, Joseph**, American clergyman and university president, great-grandson of Samuel Willard (q.v.): b. Biddeford, Me., 9 Jan. 1738; d. New Bedford, Mass., 25 Sept. 1804. He was graduated at Harvard University in 1765 and was a tutor there in 1766-72. In 1772 he was ordained in the Congregationalist ministry and became joint pastor of the First Congregationalist Church at Beverly, Mass. From 1781 until his death he was president of Harvard University. His publications include a number of sermons and some papers on astronomy and mathematics. He left an unpublished Greek grammar.

**WILLARD, Joseph Edward**, American Ambassador: b. Washington, D. C., 1 May 1865. He was graduated at the Virginia Military Institute in 1886 and later took a summer course in law at the University of Virginia. He served as a captain of United States volunteers in the Spanish-American War. He was a member of the Virginia legislature in 1894-1902; was lieutenant-governor of Virginia in 1902-06; and was State Corporation Commissioner in 1906-10. He was appointed United States Minister to Spain by President Wilson in 1913, and his rank was raised to Ambassador 13 Sept. 1913.

**WILLARD, Josiah Flynt**, American author and sociologist: b. Appleton, Wis., 23 Jan. 1869; d. Chicago, Ill., 20 Jan. 1907. While studying at the University of Berlin in 1890-95 he became interested in sociological problems, and was impressed with the danger impending to the United States through its being a haven of refuge for European criminals when their own country would no longer suffer their being at liberty. In order thoroughly to understand the situation and the actual conditions and feelings governing the tramp world he led for several years the life of a vagrant, publishing the results of his observations in 'Tramping with Tramps' (1899). His other writings include 'Powers that Prey' with F. Walton (1900); 'Notes of an Itinerant Policeman' (1900); 'The World of Graft' (1901); 'The Little Brother' (1902); 'The Rise of Rudrick Clowd' (1903).

**WILLARD, Samuel**, American clergyman, scholar and educator: b. Concord, Mass., 31 Jan. 1640; d. Boston, Mass., 12 Sept. 1707. Graduated from Harvard in 1659, he studied theology, and in 1663 was ordained minister at Groton, Mass. This village having been destroyed by the Indians (1676) during King Philip's War, he removed to Boston, where he was made colleague of Thomas Thacher, pastor of Old South, and upon the latter's death (15 Oct. 1678) succeeded to the pastorate, which he held until his death. In 1700 he became vice-president of Harvard, and in 1701, upon the resignation of President Increase Mather (q.v.) (6 Sept.), assumed the direction of the institution. He retained the active pastorate of the South Church, however, and by order of the General Court was debarred from the title of president. He was opposed to the persecutions for witchcraft, and wrote and spoke against the delusion. In 1688 he began to give a series of Tuesday afternoon lectures on theology, and these he continued for the rest of his life. The lectures were printed in 1726 in a folio of 914 double columned pages. "The thought and expression of this literary mammoth," says Tyler, "are lucid, firm, and close." Willard published numerous sermons and other writings.

**WILLARD SCHOOL, The Emma.** The Emma Willard School, which in 1914 entered on its second century of usefulness, is one of the oldest institutions for the higher education of women in the United States. It is the outgrowth of an institution founded by Emma Willard (q.v.) in Middlebury, Vt., in 1814. In 1819, the patrons of Waterford, N. Y., urged removal of the school to that place, believing the richer State of New York would grant it an appropriation. The legislature did not grant an endowment, but the application led to the allowing of a portion of the literature fund for girls' schools, to be given to the school, the first legislative appropriation of money for the education of girls. In 1821, Mrs. Willard accepted an invitation from the citizens of Troy to remove the seminary to that city, where the school became known as the Troy Female Seminary. From the establishment of the seminary in Troy in 1821, to 1875, more than 15,000 pupils were connected with the school. In 1892, a complete reorganization of the course of study was made, the art department was introduced, the boarding department was opened in Russell Sage Hall, and the old name gave way to that of Emma Willard School, thus bringing the school into close touch with its famous past and associating it in name with its illustrious founder. The school is situated in Troy, N. Y., on the Hudson River, in a healthful climate.

**WILLCOX, Cornélis DeWitt**, American army officer and educator: b. Geneva, Switzerland, 26 Feb. 1861. He came to the United States, was graduated at the University of Georgia in 1880, at the United States Military Academy in 1885, at the Artillery School in 1892, and in 1913 studied at the University of Grenoble. He was a captain of volunteers in the Spanish-American War, and in 1908-10 he was chief of the military information division at Manila, P. I. He was ap-

pointed professor of modern languages with rank of lieutenant-colonel at the United States Military Academy in 1910 and was promoted colonel in 1914. He was one of the founders of the *Journal of the United States Artillery* in 1892; and from 1915 was editor of the *International Military Digest*. In 1917-18 he was with the American Expeditionary Force in France. Besides translating several works from the Spanish he is author of 'A French-English Military Technical Dictionary' (1900; new ed., 1910); 'The Head Hunters of Northern Luzon' (1912); 'A Reader of Scientific and Technical Spanish' (1913); 'Spanish Official Account of the Attack on the Colony of Georgia' (1913); 'War French' (1917).

**WILLCOX, Orlando Bolivar**, American soldier: b. Detroit, Mich., 16 April 1823; d. Cobourg, Ontario, Canada, 10 May 1907. He was graduated from West Point in 1847, served in the Mexican War and later in the Seminole War and other Indian campaigns. He was promoted lieutenant in 1850 and in 1857 resigned from the army, thereafter engaging in law practice at Detroit until the outbreak of the Civil War, when he re-entered the army as colonel of volunteers. He was engaged at the capture of Alexandria, and at the first battle of Bull Run was wounded and taken prisoner. He was exchanged in 1862 and afterward participated in the battles at South Mountain, Antietam and Fredericksburg, led a division at the battle of the Wilderness and in the Richmond campaign, and in 1864 was brevetted major-general of volunteers. He was the first to enter Petersburg, receiving its surrender, and in 1866 was mustered out of service. He re-entered the regular army with rank as colonel in 1866, was brevetted brigadier-general and major-general in the regular army in 1867 for services at Petersburg and Spottsylvania, and was voted a Congressional medal of honor for gallantry at Bull Run in 1861. He received full rank as brigadier-general in 1886 and in the following year was retired. He wrote 'Shoepac Recollections by Walter March' (1856); and 'Faca: An Army Memoir, by Major March' (1857).

**WILLCOX, Walter Francis**, American statistician: b. Reading, Mass., 22 March 1861. He was graduated at Amherst College in 1884, at the Columbia Law School in 1887, later studied at the universities of Yale and Berlin and received the degree of Ph.D. at Columbia University in 1891. He was appointed professor of statistics and economics at Cornell University in 1901 and served also as dean of the faculty of arts and sciences in 1902-07. He was one of the five chief statisticians of the 12th United States Census in 1890-1901; was president of the American Statistical Association in 1911-12 and of the American Economic Association in 1915. His works include 'The Divorce Problem: A Study in Statistics' (1891; 2d ed., 1897); 'Supplementary Analysis and Derivative Tables, Twelfth Census' (1906). He has also contributed to periodicals and encyclopedias.

**WILLCOX, William Russell**, American lawyer and public official: b. Smyrna, N. Y., 11 April 1863. He studied at the University of Rochester and was graduated at the Columbia

Law School in 1889. He engaged in law practice in New York in 1890; served as president of the New York park board in 1902-03; and was postmaster of New York in 1905-07. He was chairman of the New York Public Service Commission in the first district in 1907-15, and in 1916 was appointed chairman of the Republican National Committee.

**WILLEMITE**, an important ore of zinc and a mineral of much mineralogical interest. It is essentially a zinc orthosilicate,  $Zn_2SiO_4$ , but all of the many varieties from Franklin Furnace and Ogdensburg, N. J., its two most prolific localities, contain considerable manganese. The colors of the New Jersey willemite are very varied, white, green, yellow, flesh-red, brown and gray, the last three being characteristic of the variety troostite which occurs in crystals up to six inches in length. The crystallization of willemite is rhombohedral, the common form being a hexagonal prism, either stout or much elongated, terminated by obtuse rhombohedrons. It occurs in small crystals of prismatic or obtuse rhombohedral habit in New Mexico. A granular form is also found in New Jersey in large quantities, intimately mixed with franklinite. Crystals from Belgium have an easy basal cleavage, but this cleavage is difficult in New Jersey crystals, which have eminent prismatic cleavage. The mineral has a hardness of 5.5 and a specific gravity of 3.9 to 4.2. Transparent crystals and masses have been found in New Jersey which yield gems whose beauty is much enhanced by the strong double refraction of the mineral, though the inferior hardness precludes their use as jewels. Ordinarily willemite is opaque, but with transparent portions scattered through the mass. The green phosphorescence of willemite when struck with a hammer has been known for many years. During exposure to the Röntgen rays and to the ultra-violet and other rays of the Piffard lamp a gorgeous green fluorescence is observed in the New Jersey mineral and some specimens are also highly phosphorescent, but these properties are not possessed by willemite from other localities. Radium salts excite instant luminescence in the New Jersey mineral. These observations have attracted widespread interest.

**WILLEMS**, *vil'lemz*, Florent, Belgian artist: b. Liège, Belgium, 9 Jan. 1823; d. Neuilly, France, 22 Oct. 1905. He studied at the Academy of Mechlin and formed his style upon that of the old Dutch masters. He removed to Paris in 1844 and was awarded first-class medals in 1855, 1867 and 1878. His work has been well received in the United States and examples of it are included in many private collections. Especially good canvases by him may be seen at the Metropolitan Museum of Art in New York, and at the Art Institute of Chicago.

**WILLEMS, Jan Frans**, Flemish philologist: b. Bouchout, near Antwerp, Belgium, 11 March 1793; d. Ghent, 14 June 1846. In 1809 he was placed in the office of an Antwerp notary, and in 1811 won a prize for the best poem on the battle of Friedland and peace of Tilsit (1811). His ode, 'Aen de Belgen' ('To the Belgians,' 1818), hailing the revival of Belgian nationality under Holland's protection,

brought him a position under the Dutch government and a series of masterly philological works, including 'Over de Nederduitsche Taal en Letterkunde' (1819-20), procured him admission to the Academy of Antwerp. On the formal separation of Belgium from Holland in 1830 he was removed from office and settling at Enclou, he labored there on the Flemish version of "Reynard the Fox," in his edition of it (1834) calling on Flemings to help to preserve their ancient tongue. As archivist of Ghent from 1835 he edited the 'Rymkronyk van Fan van Helu' (1836), 'Brabantsche Yeesten' (1839-43), etc., and after his death appeared his collection of old Flemish songs, and his 'Mengelingen van Vaderlandschen Inhoud' (Consult 'Lives' by Snellaert (1847); Rooses (1874); and Rooses, Buylsteede, and Bergmann. 'Jan Frans Willems' (1893).

**WILLET**, a large American snipe of the genus *Symphania*; sometimes called pill-willet. The bill is thick, compressed, straight, longer than the head; wings long, legs long and strong; tail short and nearly even. The *S. semipalmata* is about 15 inches long and 31 in alar extent, the bill  $2\frac{1}{2}$ ; it is darkly speckled above; rump, upper tail coverts, and under parts white; tail ashy white, the two middle feathers spotted; secondaries white, with brownish black spots. The young are spotted and transversely banded with brownish black. It is found throughout eastern temperate North America, and in South America, rarely going far from shore; on the Pacific it is represented by a distinct subspecies. It goes South in winter as far as the Gulf States where it also breeds sparingly; and is often found in company with the godwits. It breeds in both fresh and salt marshes on the ground and remains in separate flocks during the fall and winter. The eggs and the flesh, especially of the young birds, are excellent eating. The food consists of small crustaceans, and aquatic worms and insects. They are rather shy, rapid and strong fliers, and good swimmers if necessary, though they cannot dive. They are noisy while breeding, the shrill cry being reiterated as long as an intruder remains in sight. The name is derived from the resemblance of their notes to the "will-willet." Owing to their shyness, the keen sight which enables them to detect the sham of decoys, and their swift, often elevated flight they are difficult to shoot, and offer fine sport to the skillful sportsman. For these reasons, and because of their large size and excellent table qualities they are much sought. Consult Eliot, 'North American Shorebirds' (New York 1895).

**WILLETT**, Marinus, American soldier: b. Jamaica, N. Y., 31 July 1740; d. New York, 22 Aug. 1830. He served in the French War with rank as lieutenant, was especially prominent in the expedition against Ticonderoga in 1758, and in the capture of Fort Frontenac. He was active in the movements of the Sons of Liberty and on 6 June 1775 took measures to prevent the forwarding of arms from New York to the British troops in Boston Harbor. He served as captain under Montgomery in his expedition against Canada in 1775, remaining in command of the post at Saint John's until January 1776; was second in command at Fort Stanwix in

1777, led and held the fort until relieved by Arnold. In June 1794 he accepted a mission to the Creek Indians present at Monmouth, and in 1779 joined the expedition of General Sullivan against the Six Nations. He commanded the forces in the Mohawk Valley from 1780 until the close of the war, conducting in 1783 the attempted surprise of the garrison at Oswego, which was the last hostile movement against the British. In 1784-92 he was sheriff of New York, and in 1794 accepted a mission to the Creek Indians and succeeded in concluding with them a treaty of peace. He was appointed mayor of New York to succeed De Witt Clinton in 1807, and in 1812 was secretary of a mass meeting which favored military preparations against the British. He left several manuscript journals from which his son, W. M. Willett, prepared 'A Narrative of the Military Actions of Col. Marinus Willet' (1831).

**WILLETTS POINT**, N. Y., national military reservation on the south shore of East River at its entrance to Long Island Sound. The reservation comprises 136 acres, purchased partially in 1857 and partially in 1863; the construction of a fort was begun here in 1862, but the work was suspended and the fort remains unfinished. After the war an engineer battalion was ordered here to establish a depot for stores, a station for torpedo experiments, and a school of practice. The post which constitutes one of the defenses of New York Harbor is also known as Fort Totten (q.v.).

**WILLEY**, **Waitman T.**, American statesman: b. Monongalia County, Va. (now W. Va.), 18 Oct. 1811; d. Morgantown, W. Va., 3 May 1900. In 1828, at the age of 17, he entered Madison College (now Allegheny College), Pennsylvania, from which he graduated in June 1831. In 1832 he began the study of law with the distinguished Philip Doddridge at Wellsburg, Va., and in September 1833 was admitted to the bar. Thereafter he resided at Morgantown. He was clerk of both county and circuit courts of Monongalia County from 1841 to 1852. For a quarter of a century before the Civil War, he and George W. Summers of Kanawha County were universally regarded as the Whig wheel-horses of western Virginia. He was a member of the constitutional convention of Virginia, 1850-51. He was the Whig candidate for Congress in 1852, but was defeated, and was also the Whig candidate for lieutenant-governor of Virginia in 1859 but was again defeated. In 1860 he was a delegate to the constitutional union convention which nominated Bell for President. In 1861 he was a member of the Virginia convention in which he voted against the ordinance of secession. In the same year he was elected by the legislature of the "Restored government of Virginia at Wheeling" to a seat in the United States Senate, in place of James M. Mason who had resigned after the secession of Virginia. He was a member of the Wheeling constitutional convention which framed the first constitution of West Virginia, and in 1863 he was chosen to represent the new State in the Senate. In 1864 he was re-elected to the Senate for a term of six years which expired 4 March 1871. In 1871 he served as a member of the second constitutional convention of West Virginia which met at Charleston and framed the present constitution

of the State. In 1876 he was a delegate at large to the National Republican Convention which met at Cincinnati.

**WILLIAM (Friedrich Wilhelm Viktor August Ernst)**, ex-crown prince of Prussia and of the German Empire, eldest son of William II, ex-German emperor, and of ex-Empress Auguste Victoria: b. Potsdam, 6 May 1882. In 1905 he was married to Cecilie Auguste Marie, daughter of the Grand Duke Frederick Franz III, of Mecklenburg-Schwerin, of which union several sons were born. He was closely allied with the militaristic group in Germany and was often at variance with his father. He was bitterly criticized for his attitude toward the Zabern incident of 1913. He was also in disfavor with his father because of his book, 'Aus meinem Jagdtagebuch' (1912). At the outbreak of the European War, however, all differences between the emperor and the crown prince appeared forgotten. He commanded the army employed in the operations against Verdun and apparently every effort possible was exerted in the attempt to give him the prestige of victory. At the close of the war he fled to Holland where he was interned at Wieringen, an island in the Zuider Zee. Consult Liman, Paul, 'Der Kronprinz' (Minden 1914), and Gardiner, A. G., 'The War Lords' (New York 1915). See WAR, EUROPEAN—MILITARY OPERATIONS ON THE WESTERN FRONT.

**WILLIAM I**, surnamed the CONQUEROR, king of England and Duke of Normandy: b. Falaise, Normandy, 1027 or 1028; d. Rouen, 9 Sept. 1087. He was the natural son of Robert, Duke of Normandy, by Arletta, the daughter of a tanner of Falaise, and his father, having no legitimate son, when about to set out on a pilgrimage to Jerusalem, nominated him as his heir. Robert died in 1035, while returning from Palestine; and Normandy fell for a time into a condition of anarchy. When William succeeded to the dukedom his vigor and ability soon restored order, and his power increased so much as to excite the jealousy not only of the surrounding nobles, but of his suzerain the king of France. Two combinations were formed against him, and twice his territory was invaded; but he repelled these aggressions, and reduced the French king to the necessity of peace. The opportunity of gaining a wider dominion presented itself on the death of his second cousin, Edward the Confessor, king of England. When this event took place he laid claim to the English Crown, alleging that Edward had bequeathed it to him. To enforce his claim he invaded England, and the victory of Senlac or Hastings, in which his rival Harold was killed, ensured his success (1066). On the following Christmas Day, William was crowned, after tumultuary election on the part of the English nobles, and took the customary coronation oath. His first measures were mild: he sought to ingratiate himself with his new subjects, preserved his army in strict discipline, confirmed the liberties of London and other cities, and administered justice impartially. On his return to Normandy, however, the English, being treated by the Norman leaders like a conquered people, revolted, and a conspiracy was planned for the massacre of all the Normans in the country. On this intelligence William returned, and began with a show of justice by
